The genus of Sphenophyllum, investigated by Renault, Williamson and others, is highly characteristic (fig. 5, Plate). The stem is traversed by a single stele, with solid wood, without pith; the primary xylem is triangular in section, the spiral elements forming one or two groups at each angle, while the phloem occupied the bays, so that the structure resembles that of a triarch root. Two leaf-trace bundles started from each angle of the stele, and forked, in passing through to the cortex, to supply the veins of the leaf, or its subdivisions. The cortex was deeply furrowed on its outer surface. The primary structure is only found unaltered in the younger specimens; secondarily it is changed by means of a cambium set in very early, xylem being formed internally and phloem externally in a perfectly normal manner. At the same time a deep-seated periderm arose, by which the primary cortex was soon entirely cut off. The secondary wood in the Lower Carboniferous species, S. insignis, has scalariform tracheides, and is traversed by regular medullary rays, but in the forms from later horizons the tracheides are more or less pitted, and the rays are for the most part replaced by a network of xylem-parenchyma. There are no recent stems with a structure quite like that of Sphenophyllum; so far as the primary structure is concerned, the nearest approach is among the higher Psilotaceae, with which, in spite of differences, the characters indicate some affinity: the base of the stem in Psilotum forms some secondary wood. The diarch roots of a Sphenophyllum have been described by Renault, who has also investigated the leaves; they were strongly constructed mechanically, and traversed by a single vascular bundle branching dichotomously.

2. Cheirostrobus.—The family Cheirostrobeae is only known from the petrified fructification (Cheirostrobus petrycurensis) derived from the Lower Carboniferous of Burntisland in Scotland. The excellence of the preservation of the specimens has rendered it possible to investigate the complex structure in detail, but a cone is of large size—3.5 cm. in diameter; the stouter axis bears numerous whorls of compound sporophylls, the members of successive verticils being superposed. The sporophyll, of which there are eleven or

which in structure resembles the vegetative stem in its primary condition, bears numerous verticils of bracts, those of each verticil being coherent in their lower part, so as to form a disc or cup, from the margin of which the free limbs of the bracts arise. The sporangia, which are about twice as numerous as the bracts, are seated singly on pedicels or sporangiofores springing from the upper surface of the bract-verticil, near its insertion on the axis (fig. 6). As a rule two sporangiofores belong to each bract. The sporangium is attached to the enlarged distal end of the pedicel, from which it hangs down, so as to suggest an anatropous ovule on its funicle. Dehiscence appears to have taken place at the free end of the sporangium; the spores are numerous, and, so far as observed of one kind only. Each sporangiofores is traversed throughout by a vascular bundle connected with that which supplies the subtending bract. This form of fructification appears, from Zeiller's researches, to have been common to several species of Cheirostrobus, but others also show important differences. Thus Bowmanites Römeri, a fructification fully investigated by Solms-Laubsch, differs from S. Dawsoni in the fact that each sporangiofores bears two sporangia, attached to a distal expansion approaching the petal scale of the Equisetum. It is thus proved that the sporangiofores is not a more sporangial stalk, but a distinct organ, in all probability representing a ventral lobe of the subtending bract. The recently discovered species, Sphenophyllum fertile, while resembling Bowmanites Römeri in its peltate, bisporangiophorous sporangiofores, is peculiar in the fact that both dorsal and ventral lobes of the sporophyll were fertile, dividing in a palinate manner into several branches, each of which constitutes a sporangiofores. Thus the sterile bracts of other species are here replaced by sporangium-bearing sporangiophores, the latter bearing a group of sporangia and other sporangiophores, the former characterizing species of Sphenophyllum, both others also showing important differences.

Palaeobotany

Calamarian fructification (fig. 7). The great length and slender proportions of the segments give the cone a peculiar character, but the relations of position appear to leave no doubt as to the homologies with the fructification of Sphenophyllum; as regards the sporangiophores, Bennettites Komeri occurs exactly between the middle place between S. Davesoni and Chetostrous. The axis of the cone in Chetostrous contains a polyarch stem, with solid wood, from the angles of which vascular bundles pass out, dividing in the root, to give out the various segments of the sporangiophyls. In the peduncle of the strobilus secondary tissues are formed. When the anatomy has a somewhat Lycopodiaceae character, the arrangement of the appendages is altogether that of the Sphenophyllum Lycophyta, and the Calamaria are indicated by the characters of the sporangiophores and sporangia.

The Sphenophyllales as a whole are best regarded as a synthetic group, containing certain characters of the ferns and Lycopods with those of the Equisetales, while showing marked peculiarities of their own. Among existing plants their nearest affinities would appear to be with Psilotaeae, as indicated not merely by the anatomy, but much more strongly by the way in which the sporangia are borne. There is good reason to believe that the ventral sporeangium of the Psilotaeae corresponds to the ventral sporangiophyl with its sporangia in the Sphenophyllales.

Professor Thomas of Auckland, New Zealand, has brought forward some interesting variation in the Psilotaeae which afford additional support to this view.

Pseudobornia.—Professor Nathorst has described a remarkable Devonian plant, Pseudobornia urssina (from Bear Island, in the Arctic Ocean), which shows affinity both with the Equisetales and Sphenophyllales. The stem is articulated and branched, and is one of the various segments of the sporangiophyls. The fructification consists of long, lax spikes, with whorled sporophylls; indications of megaspores have been detected in the sporangia. The discoverer makes this plant the type of a new class, the Pseudoborniales. At present only the external characters are known.

III. Lycopodiales.—In Palaeozoic ages the Lycopods formed one of the dominant groups of plants, remarkable alike for the number of species and for the great stature which many of them attained. The best known of the Palaeozoic Lycopods were trees, reaching 100 ft. or more in height, but side by side with these gigantic representatives of the class, small herbaceous Club-mosses, resembling those of the present day, also occurred. Broadly speaking, the Palaeozoic Lycopods, whatever their dimensions, show a general agreement in habit and structure with those living forms, though often attaining a much higher grade of organization. We will first take the arborescent Lycopods, as in every respect the more important group. They may all be classed under the one family Lepidodendraceae, which is here taken to include Sigillaria.

Lepidodendraceae.—The genus Lepidodendron, with very numerous species, ranging from the Devonian to the Permian, consisted of trees, with a tall upright shaft, bearing a dense crown of dichotomous branches, clothed with simple narrow leaves, ranging in some complex spiral phyllostaxis. In some cases the foliage is preserved in situ; more often, however, especially in the main stem and larger branches, the leaves had been shed, leaving behind them their scars and persistent bases, on which the characteristic sculpturing of the Lepidodendron surface depends. The cones, of large size, were either terminal on the smaller twigs, or, if it is alleged, borne laterally on special branches of considerable dimensions. At its base the main stem terminated in dichotomous roots or rhizophores, bearing numerous lateral roots. To these unbranched organs the name Stigmaria is applied; they are not clearly distinguishable from the corresponding parts of Sigillaria. The numerous described species of Lepidodendron are founded on the peculiarities of the leaf-cushions and scars, as shown on casts or impressions of the stem. The usually crowded leaf-cushions are spirally arranged, and present no obvious orthostichies, thus differing from those of Sigillaria. Each leaf-cushion is slightly prominent; towards its upper end is the diamond-shaped or triangular scar left by the fall of the actual leaf (fig. 5). On the scar are three prints, the central one alone representing the vascular bundle, while the lateral prints (parichnos) mark the position of merely parenchymatous strands. In the median line, immediately above the leaf-scar, is a print representing the ligule, or rather the pit in which it was seated. On the flanks of the cushion, below the scar, are two superficial prints, perhaps comparable to lenticles. In the genus Lepidophloios the leaf-cushions are more prominent than in Lepidodendron, and their greatest diameter is in the transverse direction; on the older stems the leaf-scar lies towards the lower side of the cushion. The genus Bothrodendron, going back to the Upper Devonian, differs from Lepidodendron in its minute leaf-scar and the absence of leaf-cushions, the scars being flush with the smooth surface of the stem. In the Lower Carboniferous of central Russia beds of coal occur consisting of the cuticles of a Bothrodendron, which are not fossilized, but retain the consistency and chemical composition of similar tissues in recent plants.

The anatomy of Lepidodendron and its immediate allies is now well known in a number of species; the Carboniferous rocks of Great Britain are especially rich in petrified specimens, which formed the subject of Williamson's extensive investigations. The stem is in all cases monostele; in most of the forms the central cylinder underwent secondary growth, and the distinction between primary and secondary wood is very sharply marked. In L. Hibbertii, however, the species earliest investigated (by Witham, 1833, and Brongniart, 1837), and in one or two other species, no secondary wood has yet been found. The primary wood of Lepidodendron forms a continuous cylinder, not broken up into distinct bundles; its development was clearly centripetal, the spiral elements forming more or less prominent peripheral groups. In the larger stems of most species there was a central pith, but in certain of the smaller branches, and throughout the stem in some species (L. rhoianense, L. saligoioides), the wood was solid. A single leaf-scar, usually collateral in structure, passed out into each leaf. The primary structure of the stem was thus of a simple Lycopodiaceae type, resembling on a larger scale what we find in the upright stem of Selaginella spinulosa. In most species (e.g. L. helodendricus, L. Wünschianum, L. Feldeinum) secondary growth in thickness took place, and secondary wood was added,
primary phloem can be recognized with certainty in favourable cases, the question of the formation of secondary phloem by the cambium is not yet fully cleared up. In the Lepidodendron fuliginosum of Williamson, shown by its leaf-bases to have been a Lepidophytes, the secondary wood is irregular, and consists largely of parenchyma. The same is the case in Lepidodendron obovatum, one of the few species in which both external and internal characters are known. The occurrence of secondary growth in these plants, demonstrated by Williamson and others, is of great interest. Some analogy among recent Lycopods is afforded by the stem of Isoetes, and by the base of the stem in Selaginella spinosa; in the fossils the process was of a more normal type, but some of its details need further investigation. The development of periderm was a constant feature, and this tissue attained a great thickness, consisting chiefly of a phelloderm, produced on the inner side of the formative layer, and no doubt subserving a mechanical function.

The structure of a Bathrodonstemon has recently been investigated and described by Carruthers, to whom the name Lepidodendron mendum is due. The anatomy of the usual medullate Lepidodendron type; no secondary growth has yet been detected in the stem.

The most interesting point in the structure of the leaf-base is the presence of a ligule, like that of Isoetes or Selaginella, which was seated in a deep pit, opening on the upper surface of the cushion, just above the insertion of the lamina. The latter shows marked xerophytic adaptations; the single vascular bundle was surrounded by a sheath of short, flat sclerenchyma cells and the stomata were in deep furrows of the lower surface.

The cones of Lepidodendron and its immediate allies are for the most part grouped under the names Lepidostrobus. These cones, varying in form from simple cylindrical to cone-shaped, are supposed to have been formed by the pressure of the bases of sessile cones, though this interpretation of the scars is open to doubt, and it is now more probable that they bore deciduous vegetative branches; in the Haloniae characteristics of the genus Lepidodendron and the allies in the Upper Carboniferous. The points of insertion of pedunculate strobili. The organization of Lepidostrobus is essentially that of a Lycopodiaceous cone. The axis, which in anatomical structure resembles a vegetative twig, bears on each of its spirally arranged sporangia a single large sporangium on its upper surface (fig. 10). The sporophylls, usually almost horizontal in position, have an upturned lamina beyond the sporangium and a shorter dorsal lobe, so that the whole is somewhat peltate. A ligule is present immediately below the lamina, its position being such that the whole (fig. 11) of the elongated horizontal pedicel on which the sporangium is seated corresponds in its structure to that of the vegetative leaf. The sporangia, usually of very large size compared with those of most Lycopods, have a palisade-like outer wall, and contain either an immense number of microspores (fig. 12) or a smaller number of megasporangia. In some cases the sporangia are sparsely provided with a single megaspore, but in others the whole number of spores is four megasporangia are shown, each consisting of exceedingly large spores (fig. 10). It is very doubtful whether any homosporous Lepidostrobus existed, but there is reason to believe that here, as in the closely related Lycopods, spore and megasporangia were in some cases borne on different strobili. In other species (e.g., in the cone attributed to the Lower Carboniferous Lepidodendron Velthuesianum) the arrangement was that usual in Selaginella, the micropylar tube occurring at the megasporangia below in the same strobilus (diagram, fig. 10). The genus Sigillaria (Lower Coal Measures) differs from Lepidostrobus mainly in the insertion of the sporangium, which, instead of being attached along the whole upper surface of the sporophyll, was connected with an outgrowth from the base of the leaf. The spore masses of this genus are curiously widened and intermediate in size between the microspores and megasporangia of Lepidostrobus; the question of homospory or heterospory is not yet decided. The cones of Bothrodendron and another form named Mesostrobus are in some respects intermediate between Lepidodendron and Sigillaria. A more important deviation from ordinary Lepidodendroid structure is shown by the genus Lepidocarpon, from the English Coal Measures and the Lower Carboniferous of Scotland. In this fructification the organization is at first altogether that of a Lepidostrobus; but in each megasporangium, however, only a single megasporangium came to maturity, occupying almost the whole of the sporangial cavity (see fig. 12), but accompanied by the remains of its three abortive side cells. As development grew up from the superior surface of the sporophyll, completely surrounding the sporangium, except for a narrow crevice left open along the top. In favourable cases the prothallial tissue was preserved, within the functional megasporangium, the whole appearance, especially in a section tangential to the strobili, is then remarkably seed-like (see diagram, fig. 11). The seed-like body as detached as a whole from the cone, and in this condition was known for many years as the Vegetable Fossil. Lepidocarpon and Lepidocarpon anomalous, having been wrongly identified with a true Gymnosperm, is of seed-like form and is preserved, with the whole megasporangium, of which the seed is composed, being enclosed within the functional megasporangium of the cone. The seed-like character of the organ is even more striking in Miadmesium than in Lepidocarpon. There seems to be no near affinity between these genera in which the seed-like habit has arisen independently.

Sigillaria.—The great genus Sigillaria, next to Lepidodendron, is perhaps the most important of the Lower Carboniferous group, and is sometimes ranked among the Lepidodendroidae. It is characterized by the presence of a single sporangium in each strobilus, and by the absence of any development of integuments. Sigillaria has been assigned to the order Lepidodendripolites, but the evidence is not conclusive. Sigillaria, like the other Lepidodendroid group, was a marine plant, and its sporangia are found at the base of the crevice, which is the seat of the megasporangium (fig. 12). The megasporangium is enclosed in a single integument, which, according to its character, can be seen to have an inner microspore and an outer megaspore. It is therefore possible that the seed-like character of the organ is even more striking in Miadmesium than in Lepidocarpon. There seems to be no near affinity between these genera in which the seed-like habit has arisen independently.
In one great division of the genus—the Equiselligaria—the stems are ribbed, each rib bearing a vertical row of leaf-scars; the ribbed Sigillariae were formerly divided into two sub-genera—Rhizoidoplois, but in certain species (S. scutellata and S. mamillaris) there is evidence that they were of the Sigillariopsis type, the leaf being traversed by two parallel vascular strands, derived from the bifurcation of the leaf-trace.

The nature of the fructification of Sigillaria was first satisfactorily determined in 1834 by Zeiller, who found the characteristic Sigillarian leaf-scars on the peduncles of certain large strobili (Sigillariostrobus). The cones of which several species have been described, bear a strong general resemblance to Lepidostrobus, differing somewhat in the length of the leaf-trace. The megaspores (reaching 2 mm. or more in diameter) were found lying loose on the sporophylls by Zeiller; the sporangia containing them were first observed by Kidston, in a species from the Coal Measures at Westlar in Yorkshire. That the cones were heterosporous there can be no doubt, though little is known of the microsporangia.

The discovery of Sigillariostrobus, which was the fructification of Subsigillariae as well as of the ribbed species, has finally determined the nature of the genus Sigillaria. Sigillaria is now clearly proved to have been a genus of heterosporous Lycopsids, with the closest affinities to Lepidodendron.

Sigillaria.—On present evidence there is no satisfactory distinction to be drawn between the subterranean organs of Sigillaria and those of Lepidodendrum and its immediate allies, though some progress in the identification of special forms of Sigillaria has recently been made. These organs, to which the name Sigillaria was given by Bronnnaert, have been found in connexion with the subterranean Sigillariae. The Stigmas, which the Coal Measures they commonly occur in the underlay beneath the coal-seams. Complete specimens of the stumps show that from the base of the aerial stem (Sigillian branch) were given off, to form in an upward course, the leaf-trace, looking at least twice. These main Sigillarian axes may be 2 to 3 ft. in diameter at the base, and 30 or 40 ft. in length. Their surface is studded with the characteristic scars of their appendages as was the case with the Sigillariae. The main stem, which retained the leaf-scars of the main Stigmas, are frequent, and those of its rootlets extraordinarily abundant. The two parts are very different in structure: in the main axis, as in the common Coal Measure form Sigillaria, the stem was occupied by the xylem, which was surrounded by a phloem which was not significantly developed throughout. In other species, however, the centripetal primary xylem is represented. Phloem, surrounding the wood, is recognizable in good specimens; in the cortex the main feature is the great development of periderm. The rootlets, which have been examined and identified, contained a slender monochorone, exactly like that in the roots of Isoetes and some Selaginellae at the present day; they possessed, however, a complex absorptive apparatus, consisting of large strands of xylem, connecting the stele with the outer cortex. The morphology of Sigillaria has been much discussed; possibly the main xylem, which do not agree perfectly either with rhizomes or roots, may best be regarded as comparable with the rhizome of the Selaginellae. The roots, however, have also been compared with the embryonic stem, or protocon, of certain species of Lycopodium; the homologies of the appendages with the roots of recent Lycopsids appear manifest. It has been maintained by some paleobotanists that the aerial stems of Sigillaria arose as buds on a creeping rhizome, but the evidence for this conclusion is yet unconvincing.

Lycopodietae.—Under this name are included the fossil Lycopsids of herbaceous habit, which occur occasionally, from the Devonian onwards. One such plant, Miadesmia, has already been referred to, as one of the seed-bearing Lycopsids. In some Lycopodietae the leaves were all of one kind, while others were heterophyllous, like most species of Selaginella. The genus Selaginellae, Zeiller, is now used to include those organs which with the Lepidostrobus has proved to be heterosporous. In Selaginellae it has been a definite strobili bearing both micro- and megasporangia; in each of the latter from 16 to 24 megaspores were contained; in Selaginellae elongata, however, the number was only, as in Lycopodium; the resemblance to a recent Selaginella was thus complete. Selaginellae elongata, another heterosporous species, is remarkable for having no differentiated strobili, a condition not known in the recent genus. The antiquity of the Selaginellae type indicates that it must have arisen in connection with the Lepidostrobus, and it is a matter for surprise that the Lepidodendron has survived, having sprung from a distinct and equally ancient herbaceous stock. There is, however, some evidence that Isoetes, which in several respects agrees more nearly with the Lepidodendrane, may actually represent (see above) the Lepidodendron (P. Phanerog. E.—P. Silurico-S vaccino). No homosporous Lycopodietae have as yet been recognized.

IV. Filicaleae.—Of all Vascular Cryptogams the Ferns have best maintained their position down to the present day. Until recently it has been supposed that the class was well represented in the Palaeozoic period, and, indeed, that it was relatively, and perhaps absolutely far richer in species than in the recent flora. Within the last few years, however, the position has completely changed, and the majority of the supposed Palaeozoic
Ferns are now commonly regarded as more probably seed-bearing plants, a conclusion for which, in certain cases, there is already convincing evidence. The great majority of specimens of fossil fern-like plants are preserved in the form of carbonaceous impressions of fronds, often of remarkable perfection and beauty. The characters shown by such specimens, however, when, as is usually the case, they are in the barren state, are notoriously unstable, or of small taxonomic value, among recent plants.

Hence palaeobotanists have found it necessary to adopt a purely artificial system of classification, based on form and venation of the frond, in the absence of adequate data for a more natural grouping. The well-known form-genera Pecopteris, Sphenopteris, Odontopteris, &c., are of this provisional nature. The majority of these fronds have now fallen under suspicion and can no longer be accepted as those of Ferns; the indications often point to their having belonged to fern-like Spermatophyta, as will be shown below.

It has thus become very difficult to decide what Palaeozoic plants should still be referred to the Filices. The fructifications by themselves are not necessarily decisive, for in certain cases the supposed sporangia of Marattiaceous Ferns have turned out to be the microsporangia or pollen-sacs of seed-bearing plants (Pteridosperms). It is, however, probable that a considerable group of true Ferns, allied to Marattiaceae, existed in Palaeozoic times, side by side with simpler forms. In one respect the fronds of many Palaeozoic Ferns and Pteridosperms were peculiar, namely, in the presence on their rachis, and at the base of their pinnae, of anomalous leaflets, often totally different in form and venation from the ordinary pinnules. These curious appendages (Aphlebiae), at first regarded as parasitic growths, have been compared with the feathery outgrowths which occur on the rachis in the Cyathaceous genus Hemitelia, and with the anomalous pinnules found in certain species of Glaichenia, at the points of bifurcation of the frond.

Marattiaceae.—A considerable number of the Palaeozoic fern-like plants show indications—more or less decisive—of Marattiaceous affinities. Of this group the most important are those of the family Marattiaceae, included, as of course in the present flora, of these ferns to the family Marattiaceae, so restricted in the recent flora, rests, of course, primarily on evidence drawn from the fructifications. Typically Marattiaceous sorus, consisting of exannulate sporangia united to form synangium, are frequent, and are almost always found on fronds with the character of Pecopteris, large, repeatedly pinnate leaves, resembling those of Cyatheaee or some species of Nephrodium. In certain cases the antheridia are similar in appearance to these leaves, becoming, and found to correspond generally with that of recent coniferous fern-fronds. The petiole was usually traversed by a single vascular bundle, hippocrepiform in section—a marked point of difference from the more complex peltate fronds. There is evidence that in many cases these Pecopterid fronds belonged to arboraceous plants, the stems on which they were borne reaching a height of as much as 60 ft. These stems, known as Megaphyllum when the leaves were in two rows, and as Caulopteris in the case of polystichous arrangement, resemble some of the vegetative fronds, when petrified, so that their internal structure is preserved, the name Psaronius is employed. The structure is often a complex one, the central region containing an elaborate system of numerous pithy ducts, accompanied by sclerchyma; the cortex is permeated or coated by a multitude of adventitious roots, forming a thick envelope to the stem. The whole structure bears a general resemblance to that of recent Marattiaceae, though differing in details, which are descriptive of the fructifications, which are grouped under generic names of their own; these genera, having a more natural basis, tend to supersede the artificial groups found on vegetative characters. The genus Asterotheca includes a number of Ferns, chiefly of the Marattiaceous type. The sori, or synangia, ranged in twos or threes. When the under-side of the fertile pinnules, are circular, each consisting of 3 to 6 sporangia, attached to a central receptacle and partly united to each other (fig. 15, A); the sporangia separated when mature; the fronds were usually Central-leaved, while the sori were concentrated in a narrow band of the rachis, characterized by the separation of the sporangia, may only represent an advanced stage of an Asterotheca. In Physocarpus the fusion of the sporangia to form the synangium was much more complete, and the general character was not unlike that of Cystopteris, but each synangium is stalked. In all these genera there is an obvious similarity to the synangia of Calamites, while in some respects Marattia or Danaea is approached. In another Pecopterid genus, Sturitella, the synangium is surrounded by a cylindrical capsule, provided with a band of enlarged cells of the nature of an annulus (fig. 15, D). As a similar differentiation, though less marked, appears in the recent genus Angiopteris, the presumption is in favour of the Marattiaceous affinities of Sturitella, which also shows some relation to the genus Cystopteris (see below, Botryopteridae).

In the genus Danaea, from the Coal Measures of the Saar, the synangia are much like those of the recent Danaea, each sporangium opening by an apical pore. In the Grand-Etang of Stürmer the sporangia appear to have been free from each other, as in Angiopteris. On the whole there is thus good evidence for the frequency of Marattiaceae in the Palaeozoic period, though the possibility that the fructifications may really represent the microsporangia of fern-like Spermatophyta, must always be borne in mind. In a certain number of genera the reference to Marattiaceae is much more doubtful. In Dactylothea, for example (fig. 15, C), a Pecopterid genus, ranging throughout the Carboniferous, the elongated sporangia individually resemble those of Marattiaceae, but they are completely isolated, the characteristic grouping in sori being absent; the same remark applies to the Sphenopterid genus Renauldia of Zeiller (fig. 15, B), the foliage of Sphenopteris, on the other hand, being similar to the frond-genus of Palaeozoic frond-genus, with many different types of fructification, resembling that of various species of Astrophyllum or Davalia. In many fern-like plants of this period the fronds were dimorphic, the fertile leaves or pinnae having a form quite different from that of the vegetative portions. This was the case in Urostropteris (Kidston), with Sphenopterid sterile foliage; the sporangia, borne on the filiform pinnules of the fertile rachis, appear to have developed by an apical pore (fig. 15, J). The magnificent Devonian Fern Archaeopteris hibernica, with a somewhat Adiantiform habit, bore special fertile pinnules; the fructification is still imperfectly understood, but the presence of stipules, observed by Kidston, has been adduced in support of Marattiaceous affinities. In all these cases there is reason to suspect that the plants may have been Pteridosperms, rather than Ferns.
Other Families.—The Marattiaceae are the only recent family of Ferns which can be supposed to have existed in anything like its present form in Palaeozoic times. Of other recent orders the indications are meagre and dubious, and there can be no doubt that a large proportion of Ferns from the older rocks (as far as they were Ferns at all) belonged to families quite distinct from any which we recognize in the flora of our own day. Little or nothing is known of Palaeozoic Ophioglossaceae. Certain fructifications have been referred to Gleicheniaceae (Oligocarpus, fig. 15, E), Schizaceae (Senftenbergia, fig. 15, G), Hymenophyllaceae and Osmundaceae, and on good grounds, so far as the external characters of the sporangia are concerned; our knowledge of most of the Ferns in question is, however, far too incomplete to justify us in asserting that they actually belonged to the families indicated. In the case of the Osmundaceae there is good evidence, from anatomical characters, for tracing the family back to the Palaeozoic; their oldest members show a distinct relationship to the Botryopteridaceae described in the next paragraph. Numerous more or less isolated fern-sporangia occur in the petrified material of the Carboniferous formation; the presence of an annulus is a frequent character among these specimens, while syngamy is rare; it is thus certain that families remote from the Marattiaceae were abundantly represented during this period.

Botryopteridaceae.—The family Botryopteridaceae, first discovered by Renault, stands out with striking clearness among the Palaeozoic Ferns, and differs widely from any group now in existence. The Botryopteridaceae are known chiefly from petrified specimens; in the genus Botryopteris and certain species of Zygopteris we have a fairly complete knowledge of all parts of the plant. The type-genus Botryopteris, represented in the Perm-Carboniferous of France and in both the Lower and Upper Carboniferous of Great Britain, had a rhizome, with a very simple monostele structure, bearing spirally arranged compound leaves, with lobed pinnules, probably of a somewhat fleshy texture. In the French species, B. forestis, the plant was covered with characteristic jointed hairs, which have served to identify the various organs on which they occur. The sporangia were large, perforated sacs, shortly stalked, and borne in tufts on the branches of the fertile rachis, which developed no lamina. Each sporangium had, on one side only, a longitudinal or slightly oblique annulus, several cells in thickness; the spores were all of the same size; certain differences among them, which have been interpreted as indicating heterospory, have now proved to depend merely on the state of preservation. The genus Zygopteris, of which numerous and widely different species are known, likewise had a monostele stem, but the structure of its vascular cylinder was somewhat complex, resembling that of the most highly differentiated Hymenophyllaceae, with which some species of Zygopteris also agreed in the existence of sterile shoots. There is evidence that the stem in some species was a climbing one; the pinnate leaves, arranged on the stem in a two-or-three-filicate spiral, were dimorphic, the sterile fronds resembling some forms of the petiolar structure. It is characteristic of Zygopteris and its allies that two rows of pinnae were borne on each side of the rachis, at least in the fertile fronds. On the fertile rachis the sporangia were borne in tufts, much as in the preceding genus; they were still larger, reaching 2-5 mm. in length, and had a multi-annulate annulus, extending, however, to both sides of the sporangium (see fig. 16, A and B). In Stauropteris, a genus showing some affinity with Zygopteris, the branched rachis of the fertile frond terminates in fine branchlets, each bearing a single, spherical sporangium, without any differentiated annulus (fig. 17). The spores in the sporangia have been found in a germinating condition; the stages of germination correspond closely with those observed in recent homosporous Ferns (fig. 18). This fact strongly confirms the conclusion, drawn from morphological and anatomical characters, that the Botryopteridaceae were true Ferns.

The genus Corynextis of Baily is interesting from the fact that it has fronds almost indistinguishable from those of Zygopteris, were grouped in sori or syngangia, resembling those of an Asterotheca. The family Botryopteridaceae appears to have included a number of other genera, though in most cases the evidence from vegetative structure is alone available. The genus Diplalbis of Renault, shows much in common with Zygopteris as regards anatomical structure, but resembles Corynextis in possessing a syngamic fructification. The genus Asterotheca of Corda with a deeply-lobed stele, goes back to the Devonian. The family as a whole is of great interest, as presenting points of contact with various recent orders, especially Hymenophyllaceae, Osmundaceae and Ophioglossaceae; the group appears to have been a synthetic one, belonging to the Primofiliceae (the Primula Ferns of Arber) from which the later Fern families may have sprung.

A number of genera of Palaeozoic "fern-fronds" have been described, of the fructification of which nothing is known. This is the case, for example, with Diplomema, a genus only differing from Sphenopteris in the dichotomy of the primary pinnae, and with Mariopteris, which bears a similar relation to Pecopteris. The same holds good of the Pecopteroid Ferns included under Callipteris and Callipteridium. In such cases, as will be explained below, there is a strong presumption that the fronds were not those of Ferns, but of seed-bearing plants of the new class Pteridospermae.

On the present evidence it appears that the class Filicales was well represented in the Palaeozoic flora, though by no means so dominant as was formerly supposed. The simpler Ferns (Primulifilices) of the period are for the most part referred to the remarkable family Botryopteridaceae, a group very distinct from any of the more modern families, though showing analogies with them in various directions. On the other hand there was the far more complex Marattiacous type, strikingly similar in both vegetative and reproductive characters to the recent members of the family. Although doubts have lately been cast on the authenticity of Palaeozoic Marattiaceae owing to the difficulty in distinguishing between their fructifications and the pollen structures of ancient ferns, the anatomical evidence (Zygopteris of Psaronius) strongly confirms the opinion that a considerable group of these Ferns existed.

Spermatophyta.—The Pteridospermeae, for which Potonié's name Cycadelike is still sometimes used, include all the fern-like plants which, on the evidence available, appear to

PALAEOBOTANY

have been reproduced by means of seeds. The cases in which such evidence is decisive are but few, namely, Lyginodendron oldhamium, Neuropteris heterophylla, Pecopteris Pluck-eneti, Aneimites fertilis and Aneimtes tentusolius. In the first-named plant the structure, both of the vegetative and reproductive organs, is known, and the evidence, from comparison and association, is sufficiently strong. In the other cases there is direct proof of continuity between seed and plant, but only the external characters are known. In a great number of forms, amounting to a majority of the Palaeozoic plants of fern-like habit, the indirect evidence is in favour of their having possessed seeds. We will begin with the Lyginodendreae, a group in which the anatomical characters indicated a systematic position between Ferns and Cycads, long before the reproductive organs were discovered.

Lyginodendreae.—Of the genus Heterangium, which still stands very near the true Ferns, several species are known, the oldest being H. Grievii, of Williamson, from the Lower Carboniferous of Scotland. This plant had a long, somewhat slender, ridged stem, the ridges corresponding to the decurrent bases of the spirally arranged leaves (fig. 19). The specimens on which the genus was founded are petrified, showing structure rather than habit, but conclusive evidence has now been obtained that the foliage of H. Grievii was of the type of Sphenopteris (Diplomemna) elegans (fig. 20), and was thus in appearance altogether that of a Fern, with somewhat the habit of an Asplenium. The stem has a single stele, resembling in general primary structure that of one of the simpler species of Gleichenia; there is no pith, the wood extending to the centre of the stele. The leaf-traces, where they traverse the cortex, have the structure of the foliar bundles in Cycads, for they are of the collateral type, and their xylem is mesarch, the spiral elements lying in the interior of the ligneous strand. The leaf-traces can be distinguished as distinct strands at the periphery of the stele, as shown in fig. 21. Most of the specimens had formed a zone of secondary wood and phloem resembling the corresponding tissues in a recent Cycad; the similarity extended to minute histological details, as is shown especially in H. tiliaeoides, a Coal Measure species, where the preservation is remarkably perfect. The cortex was strongly constructed mechanically; in addition to the strands of fibres at the periphery, horizontal plates of stone-cells were present in the inner cortex, giving both stem and petiole a transversely striated appearance, which has served to identify the different parts of the plant, even in the carbonized condition (cf. figs. 19 and 20). The single vascular bundle which traversed the petiole and its branches was concentric, the leaves resembling those of Ferns in structure as well as in habit. Heterangium shows, on the whole, a decided preponderance of Filicin seatage characters, though in the leaf-traces and the secondary tissues the Cycads are approached. The organs of reproduction are not yet known, though there is a probability that an associated seed allied to Lagenasoma (see below) belonged to Heterangium. In the Coal Measure genus Megaloxylon, of Seward, which in structure bears a general resemblance to Heterangium, the primary wood consists for the most part of short wide tracheides; probably,

Coal Measures, is now the best-known of all Palaeozoic plants, the central wood has disappeared altogether and is replaced by pith; the primary wood is only represented in the leaf-trace strands, which form a ring of distinct collateral bundles around the pith;

(From a model after Oliver.)

The first definite evidence of the mode of reproduction of Lyginodendron oldhamium was due to F. W. Oliver, who in 1903 identified the seed, Lagenostoma Lomaxii, by means of the glands on its cupule, which agree exactly with those on the associated leaves and stems of the plant (cf. figs. 24 and 25). No similar glands are known on any other Palaeozoic plant. *Lagenostoma Lomaxii* is a small barrel-shaped seed (5.5 by 4.5 mm. when mature) enclosed in a husk or cupule, which completely enveloped it when young, but was ultimately open (figs. 23 and 26 and fig. 27 from another species). The seed was stalked, and there is an exact agreement in structure between the vascular strands of the stalk and cupule of the seed, and those of the rachis and leaflets of *Lyginodendron*, thus confirming the evidence from the glands. The seed itself is of a Cycadean type, and radially symmetrical. The single integument is united to the nucellus, except at the top, and is traversed by about nine vascular strands. In the apex of the nucellus, as in most Palaeozoic seeds and in recent Cycads, a pollen-chamber, for the reception of the pollen-grains or microspores (fig. 26). In *Lagenostoma* the pollen-chamber has a peculiar structure, a solid column of tissue rising up in the middle, leaving only a narrow annular crevice, in which pollen-grains are found. The neck of the flask-shaped pollen-chamber protected a little from the micropyle and no doubt received the pollen directly. The seed, which need not be described in further detail, was a highly organized structure, showing little trace of the cryptogamic megasporangium from which we must suppose it to have been derived. From the structure of the seed-bearing stalk, and from the analogy of the similar form *Lagenostoma Sinclairi* (fig. 27) it appears that the seed was borne on a leaf or part of a leaf, reduced to a branched rachis.

The male organs of *Lyginodendron* were discovered by Kidston, a year or two after the seeds were identified. They are of the type known as *Crossotheca*, formerly regarded as a Marattiaceous fructification, but now is characterized by the arrangement of the sporangia, which hang down from the lower surface of the little oval fertile leaflets, the whole resembling an epaulet with its fringe (fig. 15, F; fig. 28). In the case of *Lyginodendron* the Crossotheca occurs in contact with the vegetative parts of the frond. Each fertile pinnule bore six, or rarely seven fusiform microsporangia, described as bilocular; not improbably each may represent a synangium. The microspores are tetrahedral. This is the first case in which the pollen-bearing organs of a Pteridosperm have been identified with certainty.

It will be seen that, while the seeds of *Lyginodendron* were of an
advanced Cycadean type, the microsporangiate organs were more like those of a Fern, the reproductive organs thus showing the same combination of characters which appears in the vegetative

...compound leaves of enormous dimensions, belonging to various frond genera—especially, as has now been proved, to _Alethopteris_ and _Neuropteris_; these are among the most abundant of the Carboniferous fronds commonly attributed to Ferns, and extend back to the Devonian. In habit some species of _Alethopteris_ resembled the recent _Angiopteris_, while the _Neuropteris_ foliage may be compared with that of an _Osmunda_. The Medullosa stems have been found chiefly in the Permo-Carboniferous of France and Germany, but a Coal Measures species (M. anglica) has been discovered in Lancashire. The great anatomical characteristic of the stem of the Medullosa is its polyolec structure with secondary development of wood and bast around each stem. In _M. anglica_, the simplest species known, the steles are uniform, and usually only three in number; the structure of the stem is essentially that of a polyolec _Heterangium_. In the Permo-Carboniferous species, such as _M. stellata_ and _M. Lachnaiti_, the arrangement is more complicated, the steles showing a differentiation into a central and a peripheral system; the secondary growth was extensive and unequal, usually attaining its maximum on the outer side of the peripheral steles. In certain cases the structure was further complicated by the appearance of extrafascicular zones exterior to the whole stem system. The spirally arranged petioles (_Myloxyylon_) were of great size, and their recurrent bases clothed the surface of the stem; their structure is closely similar to that of recent Cyadoxylon petioles. In fact, the leaves generally resemble those of _Stangeria_ at the present day, while fern-like in habit, were Cycadean in structure. In the case of _Medullosa anglica_ we have an almost complete knowledge of the vegetative organs—stem, leaf and root; Cycadean characters do not predominate, but the primary organization of the stem was that of a polyolec Fern. In the new genus _Sutcliffia_, also from the Coal Measures of Lancashire, the stem had a single, large central stele, from which smaller strands were given off, forming a kind of network, which gave rise to the numerous concentric leaf-traces which entered the

*PALAEOBOTANY*

...also demonstrated that large seeds, of the size of a hazel-nut, were borne on the frond (fig. 29). In this case the internal structure is not known, but another seed, _Trigonocarpus Parkinsoni_, associated with, and probably belonging to, the _Alethopteris_ species, _Medullosa anglica_, occurs in the petrified condition and has been fully investigated. This is a large seed, with a very long micropyle; it has a beaked pollen-chamber, and a complex integument made up of hard and flay layer, closely resembling the seed of a modern Cycad; the nucellus, however, was free from the integument, each
having its own vascular system. Various other seeds of the same type are known, and in a great number of instances Grand' Eury has found the fronds of Neuropterideae (Medullosae) in close association with definite species of seeds, so there can be little doubt that the whole family was seed-bearing. Very little is known at present of the male organs. Some authors have been so much impressed by the similarity of this extinct family to the Cycads, that they have regarded them as being on the direct line of descent of the latter. This is more probable, however, that they formed a short divergent phyllum, distinct, though not remote, from the Cycadean-stock.

Pecopteridaceae.—It has now been established that the form-genus Aneitniteae, once regarded as representing the typical Marattiacese foliage, was in part made up of seed-bearing plants. In 1906 Grand' Eury discovered the seeds of Pecopteris Pluchekeni, an Upper Coal Measure species, attached, in immense numbers, to the fronds, which are but little modified as compared with the ordinary Cycadean type, and the seeds are flat and winged, closely resembling those of some Cordaitaeae (see below). Another form of fructification, compared to the sori of Dicksonia, appears to represent the male organs. There is reason to believe that other species of Pecopteris and similar genera, (Calopteris and Marattia), bore seeds, though the artificial group Pecopterideae probably also includes the fronds of true Marattiacese Ferns.

Aneitniteae.—The genus Anaitites, resembling the Maidenhair Ferns, has now been transferred to the Pteridosperms, the seeds having been discovered in 1904 by David White. In A. fertilis, from the Pottsville beds (Millstone Grit) of West Virginia, the rhomboidal seeds, flattened and winged like those of Cordaitaeae, are borne terminally on the lateral planes of a frond, whose edges bear the characteristic cuneiform leaflets. Continuity between seeds and frond was also demonstrated in another species, A. densifolius. The allied genus Eremopteris occurs in association with other genera of a similar plant-asemic type.

The Pteridosperms, of which only a few examples have been considered, evidently constituted a group of vast extent in Palaeozoic times. In a large majority of the Fern-like fossils of that period the evidence is in favour of reproduction by seeds, rather than by the cryptogamic methods of the true Ferns. The class, though closely allied to the typical Gymnosperms, may be kept distinct for the present on account of the relatively primitive characters shown in the anatomy and morphology, and may be provisionally defined as follows: plants resembling Ferns in habit and in many anatomical characters, but bearing seeds of a Cycadean type; seeds and microsporangia borne on fronds only slightly modified as compared with the vegetative leaves.

Gymnospermous remains are common in Palaeozoic strata from the Devonian onwards. The investigations of the last quarter of the 19th century established that these early representatives of the class did not, as a rule, conform to any of the typical families, but formed for the most part a distinct group, that of the Cordaitales, which has long since died out. Specimens of true Cycads or Conifers are rare or doubtful until we come to the latest Palaeozoic rocks. Our knowledge of the Cordaitaeae (the typical family of the class Cordaitales) is chiefly due to the French investigators, Grand' Eury and Renault, who successfully brought into connexion the various fragmentary remains, and made known their exact structure.

Cordaitales.—The discovery of the fossil trunks and of their rooted bases has shown that the Cordaitaeae were large trees, reaching 30 m. in height; the lofty shaft bore a dense crown of branches, clothed with long simple leaves, spirally arranged. Fig. 30, founded on one of Grand' Eury's restorations, gives an idea of the habit of a tree of the genus Dorycordaites, characterized by its lanceolate leaves; in the typical Cordaitaeae the leaves were of a blunter shape, while in Pecopteris they were narrow and grass-like. The leaves as a rule exceeded in size those of the Coniferae, attaining in some species a length of a metre. Of living genera, Agathis (to which the Kauri Pine of New Zealand belongs) probably comes nearest to the extinct family in habit, though at a long interval. The stem resembled that of Cycads in having a large pith, sometimes as much as 4 in. in diameter; the wood, however, was denser, and had the structure of that of an Araucarian Conifer; specimens of the wood have accordingly been commonly referred to the genus Araucarioxylon, and at one time the idea prevailed that wood of this type indicated actual affinity with Araucarian Conifers. Other characters, however, prove that the Cordaitaeae were remote from that family; and Araucarioxylon is best limited to wood from later horizons, where a near resemblance to Araucariaeae is more probable.1 In some cases the external

1 Endlicher's name Dadoxylon is conveniently used for Palaeozoic specimens of the kind in which nothing beyond the wood-structure is known.

boundary of the pith, as in the case in Lycopinodendron. Stems (Mesoxylon) intermediate in structure between Poroxylon and Cordaites have lately been discovered in the English Coal Measures. Artisia proving to be cause of the mediately cavity of Cordaitaeae; their true nature was first demonstrated by Williamson in 1850. In those stems which have been referred with certainty to the Cordaitaeae there is no centripetal wood; the spiral elements are adjacent to the pith, as in a recent Conifer or Cycad; certain stems, however, are known which connect this type of structure with that of the Lycopodineae; this, for example, is the case in the Permian genus Poroxylon, investigated by Bertrand and Renault, which in general structure has much in common with Cordaitaeae, but possesses strands of primary wood, mainly centripetal, at the
true Coniferae, though some resemblance to the stamens of Araucariae may be traced. The female inflorescences vary considerably in organization; in some species the axis of the spike bears solitary ovules, each accompanied by a few bracts, while in others the lateral appendages are catkins, each containing from two to several ovules. In the catkin shown in longitudinal section in fig. 32, A, it appears that each ovule was borne terminally on an extremely short axillary shoot, as in Taxus among recent Gymnosperms. The ovule consists of an integument (regarded by some writers as double) enclosing the nucellus. In the upper part of the nucellus is a cavity or 'pollen-chamber,' with a narrow canal leading into it, precisely as in the ovules of Stangeria or other Cycads at the present day (fig. 32, B). Within the pollen-chamber, and in the canal, pollen-grains are found, agreeing with those in the anthers, but usually of larger size (fig. 32, C). It was in this case that Renault first made the exceedingly interesting discovery that each pollen-grain contains a group of cells, presumably representing an antheridium (fig. 32, C). Recent observations have completely confirmed Renault's interpretation of the facts, on which some doubt had been entertained. Isolated seeds of Cordaites and of some other Gymnosperms, pollen-grains are often found within the pollen-chamber, and the pluricellular structure of these pollen-grains has been repeatedly demonstrated. In the light of our present knowledge of Ginkgo and the Cycads, there can scarcely be a doubt that spermatozoids derived from such pluricellular pollen-grains have been discovered. The antheridium of Cordaites is not yet fully cleared up, but Taxis and Ginkgo among recent plants appear to offer the nearest analogies. Much further investigation will be needed before the homologies between Cordaitesean and recent structures can be established.

Anatomically the connection of the female with the Pteridosperms (and through them, presumably, with some primitive group of Ferns) seems clear, but we have as yet no indications of the stages in the development of the structures of their reproductive organs. The class Cordaita extends back to the Devonian, and it must be borne in mind that our knowledge of their fructifications is practically limited to representatives from the latest Palaeozoic horizons. Isolated fossil seeds are common in the Carboniferous and Permian strata, in all cases they are of the type of the Anthophyta, and resemble the seeds of Cycads or Ginkgo more nearly than those of any other living plants. Their internal structure is sometimes admirably preserved, so that the endosperm with its archegonia is clearly shown (fig. 31, B, Plate). It is a curious fact that in all cases an embryo has been found in any of these seeds; probably fertilization took place after they were shed, and was followed immediately by germination. There is good evidence that many of the seeds belong to the Cordaites family, and their characters have been attributed to the group Cordaites. Many other forms of seed, and especially those which show radial symmetry, as for example Trigonocarpus, Stephanospermum and Lagerostoma, have been seen, to some of the plants occurring under Permian and Trias, but they have been regarded as seeds of plants which have flattened forms of fruit, and have been found among the几张的 or Chiefly representative of the families Pteridosperms and Araceae. The abundance and variety of Palaeozoic seeds, still so often of undetermined nature, indicate the vast extent of the sphenophytic flora of that period.

The modern Gymnospermous orders have but few authentic representatives in Palaeozoic rocks. The history of the Ginkgoales will be found in the Mesoicoic section of this article (see also Gymnosperms); their nearest Palaeozoic representatives were probably the Pteridosperms, and the Ctenophyllum order may be a remnant of which the Ginkgoaceae are closely connected. The remains referable to Cycopodium, so extraordinarily abundant in the succeeding period, are scanty. The curious genus Dicerophyllum (Scheuchzer), which of old had been attributed to the group Cordaites, from the Perm-Carboniferous of Autun, is represented by large, fleshy, reniform leaves or leaflets, with radiating dichotomous venation; the vascular bundles have in all respects the structure of those in the leaves of Cycads or Cordaitae. The male sporophylls are similar in form to the vegetative leaves, but smaller; sunk in their parenchyma are numerous tubular loculi, containing large pollen-grains, which are pluricellular like those of Cordaites; the female fructifications had not yet been identified with certainty. The curious male fructifications have perhaps been most recently discovered in the Mesozoic Cycadophyta of the group Bennettitae. Some leaves of Cycadean habit (e.g. Pterophyllum, Sphenozamites) are found in the Coal Measures and Permian, and it is possible that they may be referred to the genus Mesosperma, which was an important member of this order.

The modern Gymnosperms are largely represented by the family Gnetaceae in the Palaeozoic times. The remarkable coniferous genera described by Renault under the name Gnetopsis are of uncertain affinity, but have much in common with Lagenostoma, the seed of Lygodendron.}

---

**Palaeobotany**

in reality very distinct. Both male and female inflorescences have frequently been found in connexion with leaf-bearing branches (fig. 32). The inflorescence is usually a spike bearing lateral cones or catkins, arranged sometimes distichously, sometimes in a spiral order. The investigation of siliceous specimens has, in the hands of Renault, yielded striking results. A longitudinal section of a male Cordaites (the name applied to isolated fructifications) is shown in fig. 31, A. Plate. The organ figured is one of the catkins (about a centimetre in length) which were borne spirally on the spike. Some of the stamens are inserted between the bracts, in an apparently axillary position, while others are grouped about the apex of the axis. Each stamen consists of a long filament, bearing several erect, cylindrical pollen-sacs at its tip (cf. fig. 31, B, Plate). Some of the pollen-sacs had desiccated, while others still retained their pollen. The stamens are probably best compared with those of Ginkgo, but they have also been interpreted as corresponding to the male "flowers" of the Ginkgoaceae. In any case the morphology of the male Cordaitian fructification is clearly very remote from that of any of the Cycads or Ginkgoaceae.
Succession of Floras.

Our knowledge of vegetation older than the Carboniferous is still far too scanty for any satisfactory history of the Palaeozoic Floras to be even attempted; a few, however, of the facts may be advantageously recapitulated in chronological order.

No recognizable plant-remains, if we accept one or two doubtful Algae specimens, have so far been yielded by the Cambrian. From the Ordovician and Silurian, however, a certain number of authentic remains of Algae (among many more that are questionable) have been investigated; they are for the most part either verticillate Siphonae, or the large—possibly Laminariaceous—Algae named *Nematothecus*, with the problematical but perhaps allied *Pachytheca*. The evidence for terrestrial Silurian vegetation is still dubious; apart from some obscure North American specimens, the true nature of which is not established, Potonie has described well-characterized Pteridophytes (such as the fern-like *Sphenopteridium* and *Bothrodendron* among Lycopsids) from supposed Silurian strata in North Germany; the horizon, however, appears to be open to much doubt, and the specimens agree so nearly with some from the Lower Carboniferous as to render their Silurian age difficult of credence. The high development of the terrestrial flora in Devonian times renders it probable that land-plants existed far back in the Silurian ages, or still earlier. Even in the Lower Devonian, Ferns and Lepidodendridae have been recognized in the Middle and Upper Devonian floras of other parts of the globe, in which all the chief groups of Carboniferous plants are already represented. Considering the comparative meagerness of the Devonian record, we can scarcely doubt that the vegetation of that period, if adequately known, would prove to have been practically as rich as that of the succeeding age. Among Devonian plants, Equisetales, including not only *Archaeocalamites*, but forms referred to *Asterophyllites* and *Annularia*, occur; *Sphenophyllum* is known from Devonian strata in North America and Bear Island, and *Pseudobaria* from the latter; Lycopsids are represented by *Bothrodendron* and *Lepidodendron*; a typical *Lepidospermatum*, with structure preserved, has lately been found in the Upper Devonian of Kentucky. Fern-like plants such as *Sphenopterideae*, *Archaeopteris* and *Aneimites*, with occasional arborescent *Pecopterideae*, are frequent; many of the genera, including *Alethopteris*, *Neuropteris* and *Megalopteris*, probably belonged, not to true Ferns, but to Pteridosperms; although our knowledge of internal structure is still comparatively scanty, there is evidence to prove that such plants were already present, as for example, the genus *Calamodesmus*. The presence of *Sphenopteris* and some leaves, indicative that Gymnosperms of high organization already existed, a striking fact, showing the immense antiquity of this class compared with the angiospermous flowering plants.

Any detailed account of the horizons of Carboniferous plants would carry us much too far. For our present purpose we may divide the formation into Lower Carboniferous and Lower and Upper Coal Measures. In the Lower Carboniferous (Culm of Continental authors) many Devonian types survive—e.g. *Archaeocalamites*, *Bothrodendron*, *Archaeopteris*, *Megalopteris*, &c. Among fern-like fronds *Diplopteta* and *Rhacopteris* are characteristic. Some of the Lepidodendridae appear to approach *Sigillariae* in external characters. *Sphenophyllum* are still rare; it is to this horizon that the isolated type *Cheirolepidium* belongs. Many specimens with structure preserved are known from the Lower Carboniferous, and among them Pteridosperms (*Heterangium*, *Calamopitys*, *Cladophylon*, *Protolepidodendron*) are well represented, if we may judge by the anatomical characters. Of *Gymnosperms* we have *Archaeopteris* leaves, and the steams known as *Glyptophytes*, which probably belonged to the same family.

The Lower Coal Measures (Westphalian) have an enormously rich flora, embracing most of the types referred to in our systematic description. *Calamariaeae* with the *Arthrophytis* type of stem-structure abound, and *Sphenophyllum* are now well represented. *Bothrodendron* still survives, but *Lepidodendron*, *Lepidophloios*, and the ribbed *Sigillariae* are the characteristic Lycopsids. The heterogeneous *Ferns* grouped under *Sphenopterideae* are especially abundant. Ferns of the genera referred to *Marattiaeae* are common, but arborescent stems of the *Psaronia* type are still comparatively rare. Numerous species such as *Alethopteris* *Neuropteris*, *Maiopteris*, &c., belonged to Pteridosperms, of which specimens showing structure are frequent in certain beds. *Cordaites*, *Dorycordaites*, and many stems of the *Mezoxylon* type represent Gymnosperms; the seeds of Pteridosperms and Cordaitae begin to be common. The Upper Coal Measures (Stephanian) are characterized among the Calamariaeae, now more than ever abundant, by the prevalence of the Calamodendridae; new species of *Sphenophyllum* make their appearance; among the Lycopsids, *Lepidodendron* and its immediate allies diminish, and smooth-barked *Sigillariae* are the characteristic representatives. "Ferns" and Pteridosperms are even more strongly represented than before, and this is the age in which the supposed Marattiacceous tree-ferns reached their maximum development. Among Pteridosperms it is the family Medullosaceae which is especially characteristic. Cordaitae still increase, and Gymnospermous seeds become extraordinarily abundant. In the Upper Coal Measures the first Cycadophyta and Coniferæ make their appearance. The Permian, so far as known, is the lower in order of time, and is more certainly represented in the Coal Measures. Among the plants of the Upper Carboniferous epoch the vegetation of the world appears to have been remarkably uniform; while the deposition of the Coal Measures, however, was in progress, a differentiation of floral regions began. The sketch given above extends, for the later periods, to the vegetation of the northern hemisphere only.

**II. Mesozoic**

The period dealt with in this section does not strictly correspond with that which it is customary to include within the limits of the Mesozoic system. The Mesozoic era, as defined by geologists, begins with the Trias, and terminates with the Cretaceous epochs; but from the point of view of the evolution of plants and the succession of floras, this division is not the most natural or most convenient. Our aim is not simply to give a summary of the most striking botanical features of the several floras that have left traces in the sedimentary rocks, but rather to attempt to follow the different phases in the development of the vegetation of the world, as expressed in the contrasts exhibited by a comparison of the vegetation of the Coal period forests with that of the succeeding Mesozoic era up to the close of the Wealden period.

Towards the close of the Palaeozoic era, as represented by the Upper Carboniferous and Permian plant-bearing strata, the vegetation of the northern hemisphere and that of several regions in the southern hemisphere, consisted of numerous types of *Vascular Cryptogams*, with some members of the Gymnospermae, and several genera referred to the Pteridospermae and Cycadofilices (see section I. Palaeozoic). In the succeeding Permian period the vegetation retained for the most part the same general type, sometimes the Triassic genera died out, and a few new types made their appearance. The Upper Carboniferous and Permian plant may be grouped together as constituting a Permo-Carboniferous flora characterized by an abundance of arborescent Vascular Cryptogams and of an extinct class of plants to which the name Pteridosperms has recently been assigned—plants exhibiting a combination of Cycadean and filicaceous characters and distinguished by the production of true gymnospermous seeds of a complex type. This flora had a wide distribution in North America, Europe and parts of...
Asia; it extended to China and to the Zambesi region of tropical Africa (Map A, I. and II.).

On the other hand, the plant-beds of the Permo-Carboniferous age in South Africa, South America, India and Australia demonstrate the existence of a widely distributed vegetation which agrees in age with the Upper Carboniferous and Permian vegetation of the north, but differs from it to such an extent as to constitute a distict flora. We must begin by briefly considering this southern Palaeozoic province if we would trace the Mesozoic floras to their origin, and obtain a connected view of the vegetation of the globe as it existed in late Palaeozoic times and at the beginning of the succeeding era.

In Australia, South America and South Africa a few plant-beds have been found which agree closely with Lower Carboniferous types of the northern hemisphere. In New South Wales, for example, we have such genera as *Rhacopteris* and *Lepidodendron* represented by species very similar to those recorded from Lower Carboniferous or Cumb floras in Germany, Austria, England, Spitzbergen, North and South America and elsewhere. It is, in short, clear that the Cumb floras, as we know it in the northern hemisphere, existed in the extreme south, and it is probable that during the earlier part of the Permo-Carboniferous, a large part of the southern continents was occupied by a vegetation of similar type.

We may possibly go a step farther, and assume that the climatic conditions under which the Cumb floras of the Arctic regions flourished were not very different from those which prevailed in Europe and America during the Carboniferous period. We can see a parallel between certain plant-beds of New South Wales and South Wales overlaying Devonian and Lower Carboniferous rocks. Certain plants were discovered in the early part of the 19th century which were compared with European Jurassic genera, and for some years were considered to be the remains of plants which had been confined to the Jurassic series. These supposed Mesozoic plants include certain genera which are of special interest. Foremost among these is the genus *Glossopteris* (fig. 1), applied by Bronn in 1828 to sub-lanceolate or tongue-shaped leaves from India and Australia, which have generally been regarded as the fronds of ferns characterized by a central midrib giving off lateral veins which Anastomose and form a network, like that in the leaves of *Atrypum*, an existing member of the Polytypidae. The stems, long known from Australia and India as *Veleblavia*, have in recent years been described as the true stems of the *Glossopteris* family. It is clear that undoubted sporangia have been found in close association with *Glossopteris* leaves. The genus possessed small broadly oval or triangular leaves in addition to the large fronds like that shown in fig. 1; it is thought that these leaves were borne on long, slender stem formed certain points of resemblance to the microsporangia of modern Cycads. We cannot as yet say whether these bodies represent a somewhat unusual type of fern sporangium or whether they are microsporangia. If the latter supposition is correct the plant must have been heterosporous; but we are still without evidence on this point. Associated with *Glossopteris* occurs another fern, *Gangamopteris*, usually recognized by the absence of a well-marked midrib, though this character does not always afford a satisfactory distinguishing feature. In view of recent discoveries which have demonstrated the Pteridospore nature of many supposed ferns of Palaeozoic age, we must admit the possibility that the term fern as applied to *Glossopteris* and *Gangamopteris* may be incorrect. An Equisetaceous plant, which Bronn in 1828, is another member of the same flora; this type bears a close resemblance to *Equisetum* in the long internodes and the whitish or yellowish enging the nodes, but it is distinguished by the yellow or white, ribbon-shaped leaf-segments, as also in the structure of the cones. *Phyllocone* has been recognized in Europe in strata of Palaeozoic age, and Professor Zeiller has discovered a new species — F. Ralli — in the Moscow area. It is interesting to note that this plant bears a superficial resemblance to the Equisetaceae, which are represented by the genus *Phyllocone*.

We may next inquire what types occur in the *Glossopteris* flora agreeing more or less closely with members of the rich Permo-Carboniferous vegetation of the north. The genus *Sphenophyllum*, *Sphenopteris*, and *Glossopteris* are both well represented in the southern continents, and America is represented by a single species recorded from India, *Sphenopteris speciosa* (fig. 3), and a doubtful species from South Africa; *Amnula*, another common northern genus, is recorded from Australia, and the closely allied *Phyllocone* constitutes another link between the two Permo-Carboniferous floras. The genus *Coradias* may be compared, and indeed there is probably identical with certain forms recorded from India, South America, South Africa, and Sphenopteris speciosa. — A doubtful species from India. *Sphenopteris speciosa* (fig. 3), and a doubtful species from South Africa; *Amnula*, another common northern genus, is recorded from Australia, and the closely allied *Phyllocone* constitutes another link between the two Permo-Carboniferous floras. The genus *Coradias* may be compared, and indeed there is probably identical with certain forms recorded from India, South America, South Africa, and...
and Australia. While a few similar or even identical types may be recognized in both floras, there can be no doubt that, during a considerable period subsequent to that represented by the Lower Carboniferous or Culm rocks, there existed two distinct floras, one of which had its headquarters in the northern hemisphere, while the other flourished in a vast continental area in the south. Recent discoveries have shown that representatives of the two floras coexisted in certain regions; there was, in fact, a dovetailing between

the northern and southern botanical provinces. In 1895 Professor Zeiller described several plants from the province of Rio Grande do Sul in South America (Map A, Gs), including a few typical members of the Glossopteris flora associated with a European species, Lepidophloios laticlavis, one of the characteristic types of the Coal period, and with certain ferns resembling some species from European Permian rocks. A similar association was found also in Argentine rocks by Kurtz (Map A, Gs), and from South Africa Sigillaria Brachiophyllum, Bolbrodeni, and other northern types are recorded in company with Glossopteris, Gignemopteris and Naeggerathiopsis."The Coal-bearing strata which occupy a considerable area in China (Map A, II.), contain abundant samples of a vegetation which appears to have agreed in their main features with the Permo-Carboniferous floras of the northern hemisphere. In his account of some plants from the Coal Measures of Kansu (Map A, IV.) Dr. Krasser has drawn attention to the apparent identity of certain leaf-fragments with those of Naeggerathiopsis hislopi, a typical member of the Glossopteris flora; but this plant, so far as the evidence of vegetative leaves may be of value, differs in no essential respects from certain species of a European genus Corophite. A comparatively rich fossil flora was described in 1882 from Tongking (Map A, III.); by Professor Zeiller—and this author has recently made important additions to his original account—which demonstrates an admixture of Glossopteris types with others which were recognized as identical with plants characteristic of Rhaetic species which do not occur in the Glossopteris flora. Another plant found in the Vosges sandstones—Neuropteridium grandi folium—is also closely allied to species of the same "fern" recorded from the

Lower Gondwana strata of India (fig. 4). South America and South Africa. These two instances—the Tongking beds of Rhaetic age and the Bunter sandstones of the Vosges—afford evidence of a
northern extension of Glossopteris types and their association with European species. In 1898 an important discovery was made by Professor Amalitzky, which carries us a step further in our search for a connection between the northern and southern realms. Amalitzky recorded fossil beds of Upper Permian age in the province of Vologda (Russia) (Map A, V), species of Glossopteris and Nauggerathia of the typical members of the northern hemisphere, Permian species with migratory from the "Gondwanaland". This association of types clearly points to a penetration of representatives of the Glossopteris flora into the northern hemisphere, which was due to the climatic conditions of the Permian period. Evidence of the same northern extension is supplied by fossils described by Schmalhausen from Permian rocks in the Fuchsel valley (Map A, VI.), the Siberian genus Rheistroios being very similar, and probably generally identical with Nauggerathia of the Glossopteris flora. The Perm-Carboniferous beds of South Africa, India, and Australia are succeeded by other plant-bearing strata, containing numerous forms which are distinct only in the southern hemisphere, Permian species with members of the Rhaetic and Jurassic floras of the northern hemisphere. These post-Permian floras, as represented by the Upper Gondwana beds of India and corresponding strata in Australia, South Africa, and South America, differ but slightly from the northern floras, and are thus in the minority in the Rhaetic and Jurassic vegetation which is in contrast to the existence of two botanical provinces during the latter part of the Palaeozoic period. A few plants described by Pottini from German and Portuguese East Africa demonstrate the origin of the Glossopteris flora from other genera, referred to a Perm-Triassic horizon, in a region slightly to the north of the Tethys in the Zambesi district (Map A, I.), where typical European plants agreeing with Upper Carboniferous types were discovered several years ago, and described by Zeller in 1882 and 1901. The existence of Upper Gondwana plants, resembling Jurassic species from the Rajmahal beds of India, has been demonstrated in the Argentine by Dr. Kurtz.

Having seen how the Glossopteris flora of the south gradually spread to the north in the Permian period, we may now take a brief survey of the succession of floras in the northern hemisphere, which have left traces in Mesozoic rocks of North America, Europe and Asia. Our knowledge of the Triassic vegetation is far from extensive; this is due not in part to the fact that the conditions under which the Triassic rocks were deposited were not favourable to the existence of a luxuriant vegetation. Moreover, the Triassic rocks of southern Europe and other regions are typical marine sediments. The Bunter sandstones of the Vosges have afforded several species of Lower Triassic plants; these include the Equisetaceae genus Schizoneura—a member also of the Glossopteris flora—pinnate fern fronds referred to the genus Anomopteris, another fern, described originally as Neuropteris grandifolia, which agrees very closely with a southern hemisphere type (Neuropteris solidum, fig. 4), some large Equisetaceous stems apparently identical, varying closely with, and exhibiting, some of the same characteristics with, the European Neuropteris. Most of these occur several Conifers, among others Voltzia heterophylla and some twigs referred to the genus Alaria, bearing large leaves like those of Agathis australis and some of the Araucarias, also a few representatives of the Cycadea. Among plants from Lower Triassic strata there are a few which form connecting links with the older Permo-Carboniferous flora; of these we have a species, described by Blanckenhon as Sigillaria ocellata, which may be correctly referred to that genus, although an inspection of a plaster cast of the type-specimen in the Berlin Bergakademie left some doubt as to the sufficiency of the evidence for adopting the generic name Sigillaria. Another Triassic genus, Pseudosperm, is of interest as exhibiting, on the one hand, a striking resemblance to the recent genus Isoetes, from which it differs in its much larger stem, and on the other as agreeing fairly closely with the Palaeozoic genera Lepidodendron and Sigillaria. There is, however, a marked difference, as regards the flora as a whole, between the uppermost Palaeozoic flora of the northern hemisphere and similar species as have been recorded from Lower Triassic beds. There is evidence of a distinct break in the succession of the northern floras which is not apparent between the Permian and Trias floras of the south. Passing over the few known species of plants from the middle Trias (Muschelkalk) to the more abundant and more widely spread Upper Triassic species as recorded from Germany, Austria, Switzerland, North America and elsewhere, we find a vegetation characterized chiefly by an abundance of Ferns and Cycads, exhibiting the same general facies as that of the succeeding Rhaetic and Lower Jurassic floras. Among Cycads may be mentioned species of Pterophyllum (e.g. P. Jaegeri), represented by large pinnate fronds not unlike those of existing species of Zamiadi, some Equisetaceous plants and numerous Ferns which may be referred to such families as Gleicheniaceae, Dipteridaceae and Matoniaceae. Representatives of the Ginkgoales constitute characteristic members of the later Triassic floras, and these, with other types, carry us on without any break to the Rhaetic floras of Scandinavia, Germany, Austria, Switzerland, North America and throughout the northern and southern hemispheres. A comparative view of the plants found in various parts of the world, in beds ranging from the Upper Trias to the top of the Jurassic system, reveals a striking uniformity in the vegetation both in northern and southern latitudes during this long succession of ages. The Palaeozoic types are barely represented; the arborescent and aquatic types have been replaced by Cycads, Ginkgoales and Conifers as the dominant classes, while Ferns continue to hold their own. No undoubted Angiosperms have yet been found below the Cretaceous system. From the close of the Permian period, which marks the limit of the Upper Palaeozoic floras, to the period immediately preceding the apparently sudden appearance of Angiosperms, we have a succession of floras differing from one another in certain minor details, but linked together by the possession of many characters in common. It is impossible to consider in detail this long period in the history of plant-evolution, but we may briefly review the main characteristics of the vegetation as exhibited in the dominant types of the various classes of plants. Fragments of a Jurassic flora have recently been discovered by Dr. Anderson, a member of Norden- skold's Antarctic expedition, in Louis Philippe Land in lat. 63° 15' S. Among other well-known Jurassic genera Nanthosia has identified the following: Equisetites, Cladophlebis, Todites, Thynnfeldia, Osmoecites, Williamsoniapecten, Araucariaceae. The discovery of this Antarctic flora is a further demonstration of the world-wide distribution of a uniform Jurassic flora.

Under the head of Algae there is little of primary importance to record, but it is of interest to notice the occurrence of certain forms which throw light on the antiquity of existing families of Algae. Species of the genera Charophyta are represented by a few casts of oogonia and stem fragments, found in Jurassic and Wealden beds, which bear a striking resemblance to existing species. There is some evidence for the establishment of a similar genus of a plant of the "Phycopelites" type, in some fossilous rocks from the north German beds. Some of the fossilous rocks from the north German beds have also been cited as possible examples of the Charophyta. The oldest known Diatoms are represented by some specimens found entangled with the remains of a plant of the genus Pteridites, and some of the species of the recent genus Pyridula. The calcareous Siphonaceae are represented by several forms, identified as species of Diploneura, Trileoporea, Nemoria and other genera, from strata ranging from late Trias to the Eocene, and from Palestine, Mexico, and elsewhere. It is probable that the Jurassic Goniolina, described from French localities, and other genera which need not be mentioned, may also be reckoned among the Mesozoic Siphonaceae. A genus of the genus, compared with species of Cyanophyceae, was described as a Calcarea from Mexico and from the lime-stones of Norway.

The geological history of Mosses and Liverworts is at present very incomplete, and founded on few and generally unsatisfactory fragments. It is hardly too much to say that no absolutely trustworthy examples of Mosses have so far been found in Mesozoic strata. Of Liverworts there are a few species, such as Palaohepatica Rosafinksi from the Lower Jurassic.

t ner species, probably possessed the power of
secondary growth in thickness; the cones were of the modern type,
and the rhizomes occasionally formed large underground tubers
like those frequently met with in Equisetum arvense, E. sylvaticum
and other species. Equisetites Muensteri is a characteristic and
fairly widely spread Rhaetic and Liassic species, having a comparatively slender stem, with leaf-sheaths consisting of a few broad
and short leaf-segments. Equisetites columnaris, a common fossil
in the Jurassic plant -beds of the Yorkshire coast, represents another
type with relatively stout and occasionally branched vegetative
shoots, bearing leaf-sheaths very like those of Equisetum maximum
and other Horsetails. In the Wealden strata more slender forms
have been found e.g. Equisetites Burchardti and E. Lyelli in
England, Germany, Portugal, Japan and elsewhere, differing still

less in dimensions from modern species.
there are Schizoneurd and Phyllotheca; the former first appears in
Lower Gondwana rocks as a member of the Glossoptens flora,
migrating at a later epoch into Europe, where it is represented by
a Triassic species. The latter genus ranges from Upper Carboniferous to Jurassic rocks; it occurs in India, Australia, and elsewhere
in the " Gondwana Land " vegetation, as well as in Palaeozoic rocks
of Asia Minor, in Permian rocks ot Siberia, and in Jurassic plant-beds

Selaginellas, but lacking the more important reproductive organs.
Nathorst has recently described a new type of lycopodiaceous
cone, Lycostrobus Scotti, from Rhaetic rocks of Scania, from which
he obtained both megaspores and microspores. An investigation by
Miss Sollas of a plant long known from Rhaetic rocks in the Severn
valley as Naiadita acuminata has shown that this genus is in all
probability a small lycopodiaceous plant, and neither a Moss nor
a Monocotyledon, as some writers have supposed. One of the bestknown European species is Lycopodites falcatus, originally described
by Lindley and Hutton from the Inferior Oolite of Yorkshire.
Among the large number of Mesozoic Ferns there are several
species founded on sterile fronds which possess but little interest
from a botanical standpoint. Some plants, again, have
.
_...
ca *'*'
been referred by certain authors to Ferns, while others have
relegated them to the Cycads. As examples of these doubtful forms
may be mentioned Thinnfeldia, characteristic of Rhaetic and Lower
Jurassic rocks; Dichopteris, represented by some exceptionally fine
Jurassic specimens, described by Zigno,
from Italy; and Ctenis, a genus chiefly
from Jurassic beds, founded on pinnate
fronds like those of Zamia and other
Cycads, with linear pinnae characterized
by anastomosing veins. Plants referred
to Schimper's genus Lomatopteris and to
Cycadopteris of Zigno afford instances of
the difficulty of distinguishing between the
foliage of Ferns and Cycads. The close

Cycads persisted into the Mesozoic era; but without more anatomical knowledge than we at present possess, it is impossible to do
more than to point to a few indications afforded by external, and
to a slight extent by internal structure, of the survival of Cycadofilicinean types.
The genus Otozamites, which it is customary and
probably correct to include in the Cycadales, is represented by
certain species, such as Otozamites Beani (fig. 5, A), a characteristic
Yorkshire fossil of Jurassic age, which in the form of the frond, bearing
broad and relatively short pinnae, exhibits a striking agreement with
the sterile portions of the fronds of Aneimia rotundifolia, a member
of the fern family Schizaeaceae. Again, another species of the same
genus, 0. Bunburyanus (fig. 5, B), suggests a comparison with fern
fronds like that of the recent species Nephrolepis Duffi. The scaly
ramenta which occur in abundance on the leaf-stalk bases of fossil
Cycads constitute another fern-character surviving in Mesozoic Cycadales. Without a fuller knowledge of internal structure and of the
reproductive organs, we are compelled to speak of some of the
Mesozoic plants as possibly Ferns or possibly Cycads, and not referable with certainty to one or other class. It has been found useful
in some cases to examine microscopically the thin film of coal that
often covers the pinnae of fossil fronds, in order to determine the

form

of the epidermal cells

which

may be

preserved in the carbon-

ized cuticle; rectilinear epidermal cell -walls are usually considered
characteristic of Cycads, while cells with undulating walls are more
likely to belong to Ferns. This distinction does not, however, afford
a safe guide; the epidermal cells of some ferns, e.g. Angiopteris,
have straight walls, and occasionally the surface cells of a Cycadean
leaf-segment exhibit a fern-like character. Leaving out of account
the numerous sterile fronds which cannot be certainly referred to
particular families of Ferns, there are several genera which bear
evidence in their sori, and to some extent in the form of the leaf, of
their relationship to existing types.
The abundance of Palaeozoic plants with sporangia and sori of
the Marattiaceous type is in striking contrast to the scarcity of
Mesozoic ferns which can be reasonably included in the
„
KaratMarattiaceae.
One of the few forms so far recorded
ttaceae.
is that known as Marattia Muensteri from
Rhaetic
localities in Europe and Asia.
Some species included in the genus
Danaeites or Danaeopsis from Jurassic rocks of Poland, Austria and
Switzerland may possibly be closely allied to the recent tropical
genus Danaea. Of the Ophioglossaceae there are no satisfactory
examples; one of the few fossils compared with a recent species,
Ophioglossum palmatum, was described several years ago from
Triassic rocks under the name Cheiropteris, but the resemblance is
one of external form only, and practically valueless as a taxonomic
criterion.
It would appear that the eusporangiate Ferns suddenly
sank to very subordinate position after the Palaeozoic era.
The Osmundaceae, represented by a few forms of Palaeozoic age,
played a more prominent part in the Mesozoic floras.

names are sterile, and cannot be assigned to a particular family, but some are undoubtedly


the leaves of Todites, a genus which may often be recognized by the broad and relatively short bluntly-terminated pinnales. The Jurassic species Cladophlebis denticulata (fig. 6), recorded from several European localities, as well as from North America, Japan, China, Australia, India and Persia, affords an instance of such pinnae of bipinnate form similar to Todites Willkonschatz, which has been included in the Polypodiaceae; but such meagre evidence of the soral characters as we possess also points to a comparison with the fern of Todea barbara. Our knowledge of the ferns of fossil Osmundaceae has recently been considerably extended by Kidston and Gwynne-Vaughan. (For references, see Seward, *Fossil Plants*, vol. ii., 1910.)

The Schizaeaceae include a widely spread species, originally named *Pseudopteris exilis*, and subsequently placed in a new genus, *Klukia* (fig. 7), which is characterized by trippinate fronds with short linear ultimate segments, bearing a single row of sporangia with an apical annulus ("monangiate") stalk. Probably a member of the Schizaeaceae, has been recorded from England, Belgium, among other European countries, and Japan.

The Glossopteridaceae appear to have been represented by two species in North America and Europe, and more abundantly in Jurassic, Wealden, or Lower Cretaceous rocks in Belgium, Greenland, Poland and elsewhere. Some exceptionally perfect fragments of rhizomes have been found by Dr C. B. Clarke of Bangor, in Polonanthy, Wealden deposits at Hanhout in Belgium; but these have not yet been fully described.

A characteristic feature of the Jurassic ferns is the dichotomously-branching fronds, and the existence of a family which occupied a position in the vegetation of the far north, and which now occur only in the southern tropics of India and other regions. The recent Malayan genus *Matonia* (Map B, Matonia), represented by two species, *M. fuscata* and *M. sarmentosa*, is clearly a survival in southern regions of the Mesozoic flora, and the type of ferns which occupied an important place in the vegetation of the far north during Jurassic and Wealden periods. The genera *Laobsia* and *Matonia* (fig. B) may be cited as the two most important types, both as regards geographical and geological range.

Fig. 7.—Klukia exilis. 1—3, Sporangia enlarged.
4. Single fertile pinnae slightly enlarged.

The type represented by several recent species of *Gleichenia*, *Dichotoma, &c.*, are abundant in Lower Cretaceous plant-beds of Greenland, and suggest that in the latter part of the Mesozoic period the Gleicheniaceae held a position in the vegetation of the far north, which they now occupy in the southern tropics of India and other regions.

The recent genus *Dictyophyllum*, with its four existing species, occurring chiefly in the Indo-Malayan region (Map B, Dictyophyllum), is also a modern survival of several Mesozoic types represented by such genera as *Dictyophyllum*, which were abundant during the Early Triassic and *Combreya*, and *Pseudopteris*, which were abundant during the Jurassic and Cretaceous periods in England, Germany, Sweden and elsewhere in Europe (Map B, D). Important additions to our knowledge of the fertile leaves and rhiiforms of certain Rhacites species of *Dictyophyllum* and other genera have recently been made by Professor Nathorst of Stockholm, and Professor Richter of Japan, and the former has also described the foliage organs of *Hausmannia*, a genus possibly identical with *Protobryites*, which is abundant in Lower Cretaceous and other strata in various European localities. The Diplaziaceae are represented by species from Mesozoic rocks of Persia (Map B, D), Greenland (Map B, D), North America (D), South America (D) and China (D).

The Cyatheaceae constitute another family of leptosporangiate *Ferns* which have several representatives in Mesozoic floras. The numerous species of fronds from Japan, and some from Sweden, have been referred to *Thysanoptera*, a recent monotypic genus. But the recent *Cyathea Vischeri*, a new species discovered in the Lower Jurassic of North America and Europe referred to *Thysanoptera*, a recent monotypic genus, is a Cretaceous fern, which is possibly identical with *Protobryites*. The recent *Cyathea Cretacea—^B^, &c.* which indicate a wide Mesozoic distribution for this family. Among Jurassic species which should probably be classed as Cyatheaceae, *Conopogon humifusus* is recorded from England, France, Denmark, and also from South Africa, Japan, China, Australia and India. A few tree-ferns have been described from the Japanese and from Lower Cretaceous rocks of England, Germany and Australia. It is by no means easy in dealing with fossil ferns to distinguish between such genera as *Davalia* and members of the Cyatheaceae.

It is a striking fact that among the numerous Mesozoic ferns there are comparatively few that can with good reason be referred to a short list of genera, which are popularly known in North America and elsewhere as *Platycerium*, *Asplenium*, *Davalia*, and other Polypodiaceae genera in lists of fossil ferns is thoroughly misleading. There are many species which show traces of sori like those of modern species of *Asplenium* and other genera, but in most cases the names of recent ferns have been used on insufficient grounds.

The Wealden and Jurassic ferns of England, Germany, South Africa and Australia, bears a close resemblance to the recent *Onychium* (Cryptopteris). Other Jurassic Ferns described by Riccardi from Poland suggest a comparison with *Davalia*, *Mantonia* and *Matonia*. The resemblance of *Davalia* in association with Rhacitaceous fern leaves, and more recently figured by Halle under a new generic name (*Hydropiperangium*)—to the sporocarps of *Marilia* is an argument in favour of the early Mesozoic history of such ferns, and the specimens included in the genus *Cladophlebis*, the Mesozoic representative of the Palaeozoic Peceopteris type of frond, are known only in sterile condition, and are not assigned to their family position. *A. Wealden*, in the latter part of the Mesozoic period, is worth mention as a species of very wide geographical distribution, and one of the most characteristic members of the Wealden flora.

The type is distinguished by its large bipinnate fronds bearing long and narrow pinnae with close-set pinnae, characterized by its length and fine division of the fronds. It is a characteristic feature of *Dictyophyllum* species, and the fronds of this genus is very wide geographical distribution, and one of the most characteristic members of the Wealden flora.

The abundance of Cycadean plants is one of the most striking features of the Mesozoic floras. In no case have we only the evidence of sterile fronds, and this is necessarily unsatisfactory; *Cycadales*, but the occurrence of numerous stems and fertile shoots demonstrates the wealth of Cycadean plants in many parts of the world, particularly during the Jurassic and Wealden periods. From Palaeozoic rocks a few fronds have been described, such as *Pterophyllum Foyali*, *P. Combrayi", *Platycerium* and
**PALAEOBOTANY**

*Sphenosamites*, chiefly from French localities, which are referred to the Cycads because of their similarity to the pinnate fronds of modern Cycadaceae. In the succeeding Triassic system Cycadean fronds, which there is good reason to refer to the Cycadaceae in Upper Triassic, Rhaetic, Jurassic and Wealden rocks in India, Australia, Japan, China and elsewhere in the southern hemisphere.

from Rhaetic rocks a still greater number of types have been recorded, among which may be mentioned *Nilssonia* (fig. 10). *Anomozamites, Pierophyllum, Olozamites, Cycadites* (fig. 11). The species of *Nilssonia* shown in fig. 10 (*N. compla*) is a characteristic member of the Jurassic flora, practically identical with a form from Rhaetic rocks described as *Nilssonia polymorpha*. The large frond of *Cycadites* represented in fig. 11 (*C. Saporae*) is from the Wealden strata of Sussex, and possibly identical with *Cycadites transicatus* from Portugal. In addition to these genera there are others, such as *Clenosamites, Cenosis, and Podosamites*, the position of which is less certain. *Clenosamites* occurs chiefly in the Rhaetic coal-bearing beds of Scania, and has been found also in the Liasic clays of as well in North America, Greenland, and other Arctic lands and throughout Europe. It is noteworthy that Tertiary plant-beds have yielded hardly any specimens that can be recognized as Cycads.

A more important question is, What knowledge have we of the reproductive organs and stems of these fossil Cycads? Cycadean stems have recently been found in great abundance in Jurassic and possibly higher strata in Wyoming, South Dakota, and other parts of the United States. Cycadean stems have been found also in the uppermost Jurassic, Wealden and Lower Cretaceous rocks of England, India and other parts of the world. An example of an Indian Cycadean stem from Upper Gondwana rocks is represented in fig. 13; the surface of the trunk is covered with persistent bases (fig. 13, A) of the fronds known as *Pterophyllum cutchenii*, which are practically the same as the European species *Williamsonia peten* (fig. 17). In a section of the stem (fig. 13, B) a large pith is seen to occupy the axial region, and this is surrounded by a zone of secondary wood, which appears to differ from the characteristic wood of modern Cycads (see *Gymnosperms*) in having a more compact structure. It is in *fig. 11.—Cycadites Saporae*. interesting to find that G. R. Widland of *palaeo England.*

**Fig. 10.—Nilssonia compla*. Inferior Oolite, England.**

Dorsetshire and in the Inferior Oolite beds of Yorkshire, as well as in Rhaetic strata in Persia and elsewhere; it is characterized by its bipinnate fronds, and may be compared with the recent Australian genus *Booena*, peculiar among living Cycads in having bipinnate fronds. *Cenosis* has been incorrectly placed among the ferns by some authors, on account of the occurrence of supposed sporangia on its pinnule; but there is reason to believe that these so-called sporangia are probably nothing more than prominent papillose cells of the epidermis. *Podosamites* (fig. 12) is usually considered to be a Cycad, but the broad pinnule (or leaf) and their arrangement on the axis suggests a possible relationship with the southern coniferous genus *Aegiphila*, represented by the Kauri pine and other recent species. The considerable variation in size the pinnule of *Podosamites*, as represented by species from the Jurassic rocks in the Arctic regions and various European localities, recalls the variation in length and breadth of the leaves of *Aegiphila*. With regard to the distinguishing features and the distribution of the numerous Cycadean leaves of Mesozoic age, the most striking fact is the abundance of **Fig. 11.—Cycadites Saporae.** Wealden, England.

**XX. 18**
Yale University has noticed in some of the Cycadean stems from the Black Hills of Dakota and Wyoming that the wood appears to possess a similar structure, differing in its narrower medullary rays from the wood of modern Cycads. The lozenge-shaped areas external to the axis of the stem represent the sections of petioles of some of which are shown in fig. 13 A, attached to the stem. The majority of Mesozoic stems agree in external appearance with those of recent species of Encephalartos, Macrozamia, and some other genera; the trunk is encased in a mass of persistent petiole-bases separated from one another by a dense felt of packing of scaly ramenta. The structure of the leaf-stalks is like that of modern Cycads, but the ramenta, instead of having the form of long uniseriate hairs like those on the petals and bud-scales of existing species, are exactly like the paleae or ramental scales characteristic of the majority of ferns. This fern-like character affords an interesting survival of the close relationship between Cycads and Ferns. Some examples of Jurassic Cycadean stems from Wyoming are characterized by an unusually rich development of ramental scales; the ramenta from the old leaf-bases form an almost complete covering over the surface of the trunk. Professor Lester Ward has instituted a new generic name, Cycadelia, for these woolly forms. In a few cases the fossil stems show no trace of any lateral flowering shoots, and in that respect agree with modern forms; an instance of this kind is afforded by a large Cycadane trunk discovered some years ago in one of the Portland quarries, and named Cycadeoides gigantea (fig. 14). In this stem the flowers may have been terminal, as in existing Cycads. As a rule, however, the fossil stems show a marked difference from modern forms in the possession of lateral flowering shoots, the number of which is often many times that of the axes of leaves, and terminating in a flower of complex structure containing numerous orthotropous seeds. These reproductive shoots of the true Bennettites type so far described are from the Lower Greensand and Wealden of England, and from Upper Mesozoic strata in North America, Italy, and France. A study of the anatomical structure of the vegetative stem, which on the whole is very similar to that of recent Cycads (fig. 15, 4 and 2), reveals certain characters which are not met with in modern Cycads. The chief distinguishing feature is afforded by the leaf-traces; in recent species (see Gymnosperms) these pursue a somewhat complicated course as they pass from the petiole towards the vascular cylinder of the stem, but in Bennettites the vascular bundles from the leaves followed a more direct course through the cortex of the stem (fig. 15, 1). Owing to this striking difference, it appears to show the nearest approach to this simple structure of the leaf-traces. In a Floridian species of Zamia the leaf-traces are described as characterized by a more direct course from the stele to the leaves than in most modern genera, thus approximating Bennettites. In other genera the typical Bennettites female flower (fig. 15, 4 and 7), as investigated in English, French, Italian, and American specimens, may be briefly described as a short lateral shoot or peduncle, arising in a leaf-axis and terminating in a bluntly rounded apex bearing numerous flower-buds enclosing a central group of appendages, some of which consist of slender pedicels traversed by a vascular strand and bearing a single terminal ovule enclosed in an integument, which forms a closed and mature ovary. As a rule, the gonocarpous pedicels occur sterile appendages consisting of slender stalks, terminating in distal expansions, which form a fleshy covering over the surface of the flower, leaving small apertures immediately above the micropyles for the entrance of the pollen-grains. It has been suggested by Wieland and other authors that the almost complete development of the small Bennettites seeds by the surrounding swollen ends of the interseminal scales (fig. 15, 7) represents an approach to the angiospermous ovary. In Bennettites the ovules are left exposed at the apex, but they are by no means exclusively anomalous as in recent Cycads and Conifers. The seeds have in some cases been preserved in wonderful perfection, enabling one to make out the structure of the embryo, with its bluntly conical radicle and two fleshy cotyledons filling the equatorial cavity of the seed.

Our knowledge of the reproductive organs of the Bennettitaceae has until recently been confined to the female flowers, as described by Carruthers, Solms-Laubach, Lignier, and others. The fortunate discovery of a well-preserved example of a Bennettitacean flower, in the United States, of Lower Cretaceous and Upper Jurassic age, has supplied abundant material which has lately been investigated and is still receiving attention at the hands of Mr. Wieland. This investigator has already published a well-illustrated account of his discoveries, which have throw a wonderful light on the early history of the male organs, and lead us to expect additional results in the future of the greatest importance and interest. On some of the American stems flowers have been found, borne at the apex of lateral shoots, which possess fully developed male organs consisting of sporangia with spores (pollen-grains), surrounding a conical central receptacle bearing numerous small and probably functionless or immature ovules (fig. 15, 10). The structure of this type of flower may be briefly described as follows: A flower may be regarded as similar to that known as the female flower of Bennettites and Williamsonia. A number of hairy lateral bracts enclose the whole; internal to these occur 12 to 20 crowded pinnate leaves (sporophylls), with their apices bent or curved over the ovary. A flower, the bases of the petals being fused laterally into a disk surrounding the base of the conical receptacle. Numerous pairs of pinnules are attached to the rachis of each sporophyll, and the larger pinnules bear 20 to 30 synangia (sori or plurilocular sporangia) (fig. 15, 8 and 9). The synangial sori consist of a stroma wall of thick-walled cells, succeeded by a layer of more delicate and smaller elements; and internal to the wall occur two rows of sporangial loculi containing microspores. When the synangia are ripe desiccation takes place along a median line between the two rows of loculi. In size, position, arrangement, and manner of dehiscence the sporangia bear a striking resemblance to those of Marattia and Danaea among recent Marattiaceae. The most important point elucidated by this discovery is the very close correspondence of the male organs of the Bennettites flower with the sporrhophylls and synangia of Marattiacceous ferns—a further relic of the common origin of Cycads and Ferns. It remains to be seen if the ovuliferous cone in the center of the wood could function as a functioning gynoecium, as in Welwitschia and abnormal cones of certain Cycads, if the flowers were hermaphroditic, with both male and female organs fully developed. We have a combination in the same flower of stalked ovules, the structure of which has already been described, and the pollen-sacs constituting a compound cone, which exhibits in certain features an approach to the angiospermous type, and differs in structure from other Gymnosperm flowers, associated with male organs constructed on a plan almost identical with that of the male buds in Marattiaceous ferns. These flowers described by Mr. Wieland the structure is identical in essential features with that of the female flowers of Bennettites Gibsonianus described by Carruthers and by Solms-Laubach, and with that of certain species described by Lignier. This is a form consisting of a convex receptacle bearing mature seeds at the tips of pedicels associated with interseminal scales (fig. 15, 7) as already described. Mr. Wieland's researches have, however, demonstrated the existence in flowers of this type of the remains of a disk at the base of the sessile receptacle and the surrounding bracts, to which staminate leaves were originally attached. The flowers hermaphroditic in the Southern Hemisphere (see Gymnosperms)
but the male organs had been thrown off before the complete development of the gynoecium. This fact suggests the possibility that the flowers described by Mr Wieland, in which the male organs are mature and the gynoecium is composed of very short and immature ovuliferous stalks and interseminal scales, are not essentially distinct from those which have lost the staminate leaves that one at least of the flowers, that originally described by Mr Carruthers from the Inferior Oolite of Yorkshire as Beania gracilis, may have been borne by a member of the Ginkgoales. From Jurassic rocks of France and Italy a few imperfect specimens have been described as carpels of Cycads, like those of the recent genus Cycas (see Gymnosperms); while a few of these may have been correctly identified, an inspection of some of the original specimens in the Paris collections leads one to express the opinion that others are also imperfectly determined. Pinnate fronds of the Cycas type, characterized by the presence of a midrib and no lateral veins in the linear pinnate, are recorded from Rhätische rocks of Germany, from Wealden strata in England (fig. 11) and Portugal, and from Liassic beds in Dorsetshire. One large specimen is figured by Heer from Lower Liassic rocks of Greenland, and by the side of the frond is shown a carpel with lateral ovules, as in the female flower of Cycas; but an examination of the type-specimen in the Copenhagen Museum led the present writer to regard this supposed carpel as valueless. Professor Nathorst, as the result of a more recent examination of Heer's specimen, found that the segments of the frond are characterized by the presence of two parallel veins instead of a single midrib, with a row of stomata between them; for this type of Cycadean leaf he proposed the generic name Pseudo-cycas. Another well-known Cycadean genus is Williamsonia, so named by Mr Carruthers in 1870, and now applied to certain pinnate fronds—e.g. those previously described as Zamites gigas (fig. 10), and others known under such names as Pterophyllum or Philopteris pecten, &c., both common Jurassic species—as well as to stems bearing peduncles with terminal oval flowers, similar in form to that of Bennettites. There is good evidence for supporting Professor Williamson's conclusions as to the organic connexion between the flowers, originally described from Inferior Oolite rocks of Yorkshire and subsequently named Williamsonia (fig. 15, 4), and the fronds of Zamites gigas, now known as Williamsonia gigas (fig. 16). There can be little doubt that the majority of the Cycadean fronds of Jurassic and Wealden age, which were nearly always found detached from the rest of the plant, were borne on stems of the Bennettitalean type. Williamson was the first to express the opinion that the Bennettitalean flowers of Williamsonia are borne on the trunks which terminated in a crown of pinnate fronds of the type long known as Zamites gigas; this view was regarded by Saporta and others as incorrect, and the nature of the Bennettitalean foliage was left an open question. A re-examination of the English material in the museums of Paris and elsewhere has confirmed Williamson's conclusions. Mr Wieland has also described young bipinnate fronds, very like those of recent species of Zamia and Euphyllopteris, attached to a Bennettitalean stem and exhibiting the same venation characters of many recent Cycads (fig. 15, 5). In Williamsonia the stem bore comparatively long fertile shoots, which, in contrast to those of Bennettites, projected several inches beyond the surface of the main trunk, and terminated in a flower which appears to have resembled those of the true Bennettitalean type. Nathorst has recently described specimens of Williamsonia from the Jurassic rocks of Whitby with micro-Sporophyta like those of Wieland's species. Williamsonia occurs in the Upper Gondwana rocks of India; it is recorded also from the Jurassic strata from the Rhätische to the Lower Cretaceous period in England, Portugal, Sweden, Bornholm, Greenland, Italy and North America. Professor Nathorst has described another type of stem from the Rhätische beds of Scania. It consists of a comparatively small and repeatedly forked axis bearing in each fork a flower; the flowers, which are regarded as male and female, appear to be similar to those of Bennettites. The leaves, borne on the regions between the false dichotomies, are those of Anemozamites minor, a type of Cycadean frond originally determined.
by Brongniart. The flowers, or some of them, were originally described by Nathorst as *Williamsonia angustiloba*. This form of stem, of a habit entirely different from that of recent Cycads and extinct *Bennettites*, points to the existence in the Mesozoic era of another type of Gymnosperm allied to the *Bennettites* of the Jurassic and Cretaceous periods by its flowers, but possessing a distinctive character in its vegetative organs. There is no doubt that the Cycadophyta, using the term suggested by Nathorst in 1902, was represented in the Mesozoic period by several distinct families or classes which played a dominant part in the floras of the world before the advent of the Angiosperms. In addition to the bisporangiate reproductive shoots of *Bennettites*, distinguished by many important features from the flowers of recent Cycads, a few specimens of flowers have been discovered exhibiting a much closer resemblance to those of existing Cycads, e.g. *Androstrobus thalwalti* from Bartholinian rocks of France; *Zamites familiaris*, described many years ago by Corda, from Lower Cretaceous rocks of Bohemia, and *Androstrobus Nathorstii*, from Wealden beds in Sussex. The majority of the species were, however, characterized by flowers of a different type known as *Bennettites* and *Williamsonia*.

The living Maidenhair-tree (*Ginkgo biloba*) (see *Gymnosperms*) remains, like *Matonia* and *Dipteris*, among the ferns, as an isolated relic in the midst of the *Ginkgoales*, of recent vegetation. In Rhaetic, Jurassic, and Wealden floras, the *Ginkgoales* were exceedingly abundant (Map B, G1–G7); in addition to leaves agreeing almost exactly with those of the recent species (fig. 18), there are others separated as a distinct genus, *Baiera* (fig. 18, G), characterized by the greater number and narrower form of the segments, which may be compared with such leaves as those of the recent fern *Achnipteris* and certain species of *Schizaeas*. Male flowers, like those of *Ginkgo biloba*, but usually characterized by a rather larger number of oval pollen-sacs on the stamens, have been found in England, Germany, Siberia and elsewhere in association with *Ginkgo* and *Baiera* foliage. The occasional occurrence of three or even four pollen-sacs on the stamens of the recent species affords a still closer agreement between the extinct and living types. Seeds like those of *Ginkgo biloba* have also been recorded as fossils in Jurassic rocks, and it is possible that the type of flower known as *Beania*, from the Inferior Oolite rocks of Yorkshire, may have been borne by *Ginkgo or Baiera*.

and Wealden age, but an abundance of fossil wood (*Araucarioxylon*) from Jurassic and Cretaceous strata in Europe, North America, Madagascar and elsewhere agreeing with that of recent *Araucariaeae*, in addition to several well-preserved female flowers. C. A. Hollick and E. C. Jeffrey have recently shown that some Lower Cretaceous specimens of the well-known genus *Brachyphyllum* obtained from Isle of Wight, England, N.Y., possess wood of the *Araucariaeae* type. This genus has long been known as a common and widely spread Jurassic and Cretaceous conifer, but owing to the absence of petrified specimens and of well-preserved cones, it has been impossible to refer it to a definite position in the Coniferae. It is now clear that some of the species of *Brachyphyllum* must be referred to the *Araucariaeae*. In a recently published paper Seward and Ford have given a general account of the *Araucariaeae*, recent and extinct, to which reference may be made for further details as to the geological history of this ancient section of the Coniferae. Some of the fossils referred to the genus *Kaidocarpus*, and originally described as monocotyledonous inflorescences, are undoubtedly *Araucarian* cones; other cones of the same type have been placed in the genus *Cycadeostrobus* and referred to Cycads. *Araucariaceae Iludlestoni*, described by Mr Carruthers from the Coralline Oolite rocks of Malton in Yorkshire; *Araucariaceae sphaerocephala* from the Inferior Oolite of Somersett, also another cone found in the Northampton Sands, which is probably specifically identical with *A. Iludlestoni*, and named by Carruthers *Kaidocarpus ooliticum*, afford good illustrations of British Jurassic flowers. A flower of a rather different type, *Pseudaracaraceae major*, exhibiting in the occurrence of seeds in both scale an approach to the cones of *Abietineae*, has been described by Professor Fliche from Lower Cretaceous rocks of Argonne. The well-known Whitby jet of Upper Liassic age appears to have been formed to a large extent from *Araucarian* wood. Among the more abundant Jurassic teeth of *Araucariaeae* may be mentioned such genera as *Thyletes* and *Cupressaceae*, which agree in their vegetative characters with members of the *Cupressinae*, but our knowledge of the cones is far from satisfactory. Many of ours born on shales with foliage of the *Cupressaceae* type consist of spiral disposed and not verticillate scales, e.g. *Thyletes expansus*, a common Jurassic species.

Fossil wood, described under the name *Cupressinoxylon*, has been recorded from several Mesozoic horizons in Europe and elsewhere, but this term has been employed in a wide sense as a designation for a type of structure met with not only in the *Cupressinae*, but in members of other families of Coniferae. The *Abietineae* do not appear to have played a prominent part before the Wealden period; various other species, e.g. *Abietineae* specimens from *Scania*, are recorded, but it is not until we come to the Upper Jurassic and Wealden periods that this modern family was abundantly represented. Fossil wood of the *Piniaceae* type (*Pityoxylon*) has been described from England, France, Germany, Sweden, Spitsbergen, North America and elsewhere; some of the best British examples have been obtained from the so-called Pine-raft, the remains of water-logged and petrified wood of Lower Greensand age, seen at low water near Brook Point in the Isle of Wight. Well-preserved *Abietineae* female flowers have been obtained from the Wealden rocks of England and Belgium, e.g. *Piniaceae Dunkeri*, *P. Solmi*, &c.; specimens of seeds and vegetative shoots are recorded also from Spitsbergen and other regions. Hollick and Jeffrey have recently added to our knowledge of the anatomy of *Cretaceous*
species of Pinus, and Miss Stopes and Dr Fujii have made important contributions on the structure of Cretaceous plants from Japan. Cones of Lower Cretaceous age have been described by Fliche from Argonne, which bear a close resemblance to the female cones of recent species of Cedrus. The two surviving species of Sequoia afford an illustration of the persistence of an old type, but unfortunately most of the Mesozoic species referred to this genus do not possess sufficiently perfect cones to confirm their identification, as examples of Sequoia. Some of the best examples of cones and twigs referred to Sequoia are those described by Heer from Cretaceous rocks of Greenland, and Professor D. P. Penhallow of Montreal has described the anatomical structure of the stem of Sequoia tamosa, a Tertiary species occurring in Europe and North America.

There are a few points suggested by a general survey of the Mesozoic floras, which may be briefly touched on in conclusion. In following the progress of plant-life through those periods in the history of the earth of which records are left in ancient sediments, seams of coal or old land-surfaces, we recognize at certain stages a want of continuity between the floras of successive ages. The imperfection of the geological record, considered from the point of view of evolution, has been rendered familiar by Darwin's remarkable chapter in the Origin of Species. In the chain of life, as represented by gaps in the blurred and incomplete documents afforded by fragmentary fossils, are a necessary consequence of the general plan of geological evolution; they manifest the chapters rather than the sudden breaks in any evolutionary series. On the other hand, a study of the plant-life of past ages tends to the conviction that too much stress may be laid on the imperfection of the geological record as a factor in the interpretation of palaeontological data. The doctrine of Uniformitarianism, as propounded by Lyell, served to establish geology on a firmer and more rational basis than it had previously possessed; but latterly the tendency has been to modify the Lyellian view by an admission of the probability of a more intense action of groups of forces at certain stages of the earth's history. As a definite instance a short review may be given of the evidence of palaeobotanical records as regards their bearing on plant-evolution. Starting with the Permo-Carboniferous vegetation, and omitting for the moment the Glossopteris flora, we find a comparatively homogeneous flora of wide geographical range, consisting to a large extent of arborescent lycopsids, calamites, and other vascular cryptogams, plants which occupied a place of importance in the flora of the Carboniferous in our modern forests; with them were other types of the gymnospermous type, which serve as finger-posts pointing to lines of evolution of which we have but the faintest signs among existing plants. Other types, again, which may be referred to the Gymnosperms, played a not unimportant part in the Palaeozoic vegetation. No conclusive proof has so far been adduced of the existence in those days of the Cycads, nor is there more than partial evidence of the occurrence of genera which can be placed with confidence in any of the existing families of Conifers. There are, moreover, no facts furnished by fossil plants in support of the view that Angiosperms were represented either in the low-lying forests or on the slopes of the mountains of the Coal period. Passing higher up the geological series, we find but scanty records of the vegetation that existed during the closing ages of the Permian period, and of the plants which witnessed the beginning of the Triassic period we have to be content with the most fragmentary. The Upper Triassic and the Rhaetic age that abundant remains of rich floras are met with, and an examination of the general features of the vegetation reveals a striking contrast between the Lower Mesozoic plants and those of the Palaeozoic period. Arborescent Pteridophytes are barely represented, and such dominant types as Lepidodendron, Sigillaria, Calamites and Sphenophyllum have practically ceased to exist; Cycads and Conifers have assumed the leading rôle, and the still luxuriant fern vegetation has put on a different aspect. This description applies almost equally to the floras of the succeeding Jurassic and Wealden periods. The change to this newer type of vegetation was no doubt less sudden than it appears as read from palaeobotanical records, but the transition period between the Palaeozoic type of vegetation and that which flourished in the Lower Mesozoic era, and continued to the close of the Wealden age, was probably characterized by rapid or almost sudden changes. In the southern hemisphere the Glossopteris flora succeeded a Lower Carboniferous vegetation with a rapidity of transition that marked the passage in the north from Palaeozoic to Mesozoic floras. This apparently rapid alteration in the character of the southern vegetation took place at an earlier period than that which witnessed the transformation in the northern hemisphere. The appearance of a new type of vegetation in India and the southern hemisphere was probably connected with a widespread lowering of temperature, to which reference has already been made. It was from this Glossopteris flora that several types gradually migrated across the equator, where they formed part of the vegetation of more northern regions. The difference between the Glossopteris flora and those which have left traces in the Upper Gondwana rocks of India, in the Wianamatta and Hawkesbury beds of Australia, and in the Stormberg series of South Africa is much less marked than that between the Permo-Carboniferous flora of the northern hemisphere and the succeeding Mesozoic vegetation. In other words, the change took place in a later period in the south than in the north. To return to the northern hemisphere, it is clear that the Wealden flora, as represented by plants recorded from England, France, Belgium, Portugal, Russia, Germany and other European regions, as also from Japan and elsewhere, carries on, with minor differences, the facies of the older Jurassic floras. It was at the close of the Wealden period that a second evolutionary wave swept over the vegetation of the world. This change is most strikingly illustrated by the inrush of Angiosperms, in the equally marked decrease in the Cycads, and in the altered character of the ferns. It would appear that in this case the new influence, supplied by the advent of Angiosperms, had its origin in the north. Unfortunately, our knowledge of the later floras in the southern hemisphere is very incomplete, but a similar transformation appears to have characterized the vegetation south of the equator. As to the nature of the chief factors concerned in the two revolutions in the vegetable kingdom, if it is admissible to use so strong a term, we are still ignorant. What doubt played an important part, but whatever cause may have had the greatest share in disturbing the equilibrium of evolution forces, it would seem that the apparently sudden appearance of Cycads and other types at the close of the Palaeozoic period made a widespread and sudden impression on the whole character of the vegetation. At a later stage—in post-Wealden days—it was the appearance of Angiosperms, probably in northern latitudes, that formed the chief motive power in accelerating the transition in the facies of plant-life from that which marked what we have called the Mesozoic floras, to the vegetation of the Upper Cretaceous and Tertiary periods. With the advent of Angiosperms began, as the late marquis of Saporta expressed it, “Une révolution, ainsi rapide dans sa marche qu'universelle dans ses effets.” From the floras of the Tertiary age we pass by gradual stages to those which characterize the present phase of evolutionary progress. Among these we find floras of mixed types, such as Ginkgo, Sequoia, Matonia, Dypsis and the Cycads, as well as more successful survivals which have held their own course through the ages. These floras remain as vestiges from a remote past, and as links connecting the vegetation of to-day with that of the Mesozoic era.

PALAEOBOTANY

The earliest Angiosperm yet found in Europe is a single monocotyledonous leaf of doubtful affinities, named by Saporta

**Amaranthus primus** (fig. 1), and found in the Valen
ginin series of Portugal. These deposits seem to be equivalent to British Wealden rocks,
though in the latter, even in their upper part, no trace of Angiosperms has been discovered.

No other undoubted Angio

osperm has yet been discovered in Europe

in strata of this age, but Heer records a poplar-like leaf from Urgonian strata, a stage

tamer than the Valen
ginian, in Greenland, and Saporta has described from strata of the same date in Portugal a

Euphorbiaceous plant apparently closely allied to the living Phyllanthus and named by

him Chofatio Francheti (fig. 2). We must turn to North America for a fuller

knowledge of the earliest flowering-plants.

In S. Dakota a remarkable series has been discovered, lying

unmistakably between the Urgonian and Jurassic rocks below and above

Cretaceous strata. There has been a certain amount of confusion as to the

true position of the plants occur, but this has now been cleared up by the

researches of Lester F. Ward, who has shown how the Secondary flora gives

to place to one of Tertiary character.

The lower strata—i.e. those most allied to the Jurassic—

contain only Gymnosperms and Cryptogams. The next division (Dakota

No. 2 of Meek and Hayden)

contains Gymnosperms and Ferns of Neocomian type, as well as

a number of Neocomian species; but mingled with these occur a few dicotyle
donous leaves belonging to four genera, the specific characters of which are

still fragmentary, and all that can be said is that one of the forms may be

alike to oak, another to fig, a third to *Sapindus*, and a fourth to *Cedrus* or

may perhaps be near to elm.

The *Potamophyllum Formation* of Virginia and Maryland is doubtless also

mainly of Neocomian age, though it rests unconformably on much

older strata, the successional flora found in it are so different to those of S. Dakota as to

be hardly included in the same group. Nevertheless, the species of the *Potamophyllum* are

a peculiarly interesting one, and the genus may perhaps be near to *Elm*.

The *Pomatophyllum Formation* of Virginia and Maryland is doubtless also

mainly of Neocomian age, though it rests unconformably on much

older strata, the successional flora found in it are so different to those of S. Dakota as to

be hardly included in the same group. Nevertheless, the species of the *Potamophyllum* are

a peculiarly interesting one, and the genus may perhaps be near to *Elm*.

The *Potamophyllum Formation* of Virginia and Maryland is doubtless also

mainly of Neocomian age, though it rests unconformably on much

older strata, the successional flora found in it are so different to those of S. Dakota as to

be hardly included in the same group. Nevertheless, the species of the *Potamophyllum* are

a peculiarly interesting one, and the genus may perhaps be near to *Elm*.
though already more than 350 species have been determined from this newer series. The plants from the Abboy Clay, which form the most important division of the Newer Potomac series and were monographed in 1895 by J. S. Newberry, seem to belong to the com-
munity of the Neocomian and Cretaceous.
It is remarkable that nearly 80% of the species are Dicotyledons, and that no Monocotyledons have been found. The mere enumeration of the genera will indicate how close the flowering plants are to living forms, and the following are the most noteworthy species of the Salix (5 species), Quercus, Planera, Ficus (3 species), Persea, and another extinct Proterozoic genus named Proteoides, Magnolia (7 species), Liriodendron (4 species), Menispermites, Laurus and all their allies. Among the Cryptogams, the Lycopods of the genus Equisetum (8 species), Lepidodendron (4 species), Myrurus, Sphenophyllum, Dicotyledons, Acoraceae, and various genera of uncertain affinities. The points that suggest themselves with regard to this flora are, that it includes a fair representation of the flora of the upland, temperate, mono-
tropic trees; that the more primitive types—such as the Amentacae—do not appear to preponderate to a greater extent than they do in the existing temperate flora; that the assemblage somewhat suggests American affinities; and that, while the highest take into account deficient conditions, and the non-preservation of soft local plants, there is no reason for saying that certain other orders must have been absent. The great rarity of Monocotyledons is a common characteristic of fossil floras known only, as this one is, from leaves practically belonging to evergreen trees. With regard to so-called American affinities, it must be borne in mind that the Neocomian flora is not formed by a world-wide distribution. We know that this was the case with some, such as Liriodendron; and in Equisetum we see the converse, whose genus formerly American is now confined to a far distant region. The Neocomian flora has been preserved from an area extending over about 35° of latitude; but there is little evidence of any corresponding climatic change. We cannot yet say, however, that the deposits are exactly contemporaneous, and the great climatic variations that have taken place since the existence of these ancient trees can be explained away. The flora should make us hesitate to correlate too minutely from the evidence of plants alone.

The highest division of the Dakota series (known as the Dakota) is not one that lies immediately beneath the Upper Cretaceous strata with marine fossils, contains a flora so like that of the Tertiary deposits that only the clearest geological evidence has been considered sufficient to prove that Heer was wrong when he spoke of the plants as Miocene. The higher plant-bearing strata rest, according to Lester Ward, somewhat unconformably on the Dakota No. 2; they show also a marked difference in the included plants. The genera of Dicotyledons represented are Quercus, Sassafras, Phellodendron, Viburnum, Stilites, Eucalyptus, and others. In the central parts of North America the lacustrine plant-bearing deposits are of enormous thickness, the Dakota series being followed by marine Cretaceous strata known as the Colorado and Montana groups. The deposits have been divided into several members or beds of lacustrine shales, sandstones, and conehelms, belonging to the Laramie series. This also contains occasional marine Upper Cretaceous fossils, as well as reptiles of Cretaceous types. An extensive collection of the earlier writers included in the Lower strata, for owing to the Tertiary aspect of the contained plants, geologists were slow to recognize that they could be truly contemporaneous and interbedded with others yielding Cretaceous animals. In addition to the Dakota No. 2, the earlier writers included in the Lower strata, for owing to the Tertiary aspect of the contained plants, geologists were slow to recognize that they could be truly contemporaneous and interbedded with others yielding Cretaceous animals. In addition to the Dakota No. 2, the earlier writers included in the Lower strata, many deposits now known to have existed in that place and truly Tertiary, and the process of separation is even now only partially completed. It will be safest in these circumstances to accept as our guide to the flora the so-called ‘Catalogue’ of F. H. Knowlton. According to this catalogue, the true Laramie flora includes about 250 species, more than half of which are deciduous forest trees, herbaceous Dicotyledons, Monocotyledons, and Cryptogams, all being but poorly represented. Among the few Monocotyledons are leaves and fruits of palms, and traces of grasses and sedges. The Dicotyledons include several water-lilies, a somewhat doubtful Tropa, and many genera of forest trees still considerable. The genera best represented are Ficus (21 species), Quercus (16 species), Populus (11 species), Robinia (9 species), and others. The flora is remarkable for, no fewer than 6 genera, containing 8 species, are referred to the Proteaceae, which is an order of the Invasion of the Cretaceous flora of Bohemia is large and equally peculiar. Among the Dicotyledonous leaves described, the following are the following: Credneria (5 species), Aralaceae (17 species), Proteaceae (8 species), Myrica (3 species), Ficus (2 species), Magnoliaceae (5 species), Bombacaceae (3 species), Lauraceae (2 species), Vitaceae (2 species), Verbenaceae, Combretaceae, and Sapindaceae (2 species), Camellaceae, Amaryllidaceae, and Bignoniaceae (5 species), Eucalyptus (2 species), Pisonia, Phyllirea, Rhous, Prunus, Bignonia,
The British Eocene and Oligocene strata yield so large a flora, and certain plant-beds belonging to so many different stages, that it is unfortunately not even possible to monograph on the subject, the one commenced by Ettingshausen and Gardner in 1879 having reached no further than the Ferns and Gymnosperms. This deficiency makes it impossible to deal adequately with the British Eocene plants, most of the material being either unpublished or needing re-examination.

In the earliest Eocene plant-beds, in the Woolwich and Reading series, we have also yielded a few species found, which may indicate a slightly more temperate climate than that of earlier or later periods. Leaves of plants are abundant, and among the plants recorded are two ferns, a laurel, and a palm. Ferns are scarce, Eocene and Oligocene, pure Gymnosperms; the only species represented are Libocedrus adpressa, which is close to L. decurrens of the Yosemiti, and Taxodium europaeum. A few plants have been found in the next stage, the Oldham beds, and among these are ferns and clavata. These species are closely related to tropical and conditions. The London Clay has yielded a large number of plants, but most of the species are represented by fruits alone, not by leaves. This circumstance makes it difficult to compare the flora with that of other strata or periods. Among the leaves and fruits belong to the same plant, but there is the additional source of doubt, that different elements of the same flora may be represented in different localities. Of some species only the deciduous leaves are represented, and it is evident that the deciduous leaved plants will only be known from their woody fruits. Among the 200 plants of the London Clay are no Ferns, but 6 genera of Gymnosperms—v.f. Calitris (2 species), Sequoia, Athroclus (3) Gymnospermus and Calamites genera of palms, of which the tropical Nipa is the most abundant and most characteristic, among the others being fan-palms of the genera Sabal and Chamaerops. The Dicotyledons need further study. Among the fruits Ettinghausen has referred to Eocene beds, Diospyros, Sycamore, Magnolia, Victoria, Hightea, Sapindus, Cupania, Eugenia, Eucalyptus, Amygdalus; he suggests that the fruits of the London Clay of Sheppey may belong to the same plant, as the leaves found at Alum Bay in the Isle of Wight.

The later stages of the London Clay are also barren of leaf-beds of Alum Bay. These piperidens yield a varied flora, Ettinghausen recording 274 species, belonging to 116 genera and 63 families. Gardner, however, is unable to reconcile this estimated richness with our knowledge of the present day flora from other localities must have been inadvertently included. He considers the flora to be the most tropical of any that has so far been studied in the northern hemisphere. Its most conspicuous plants are Calitris, Sequoia, Eucalyptus, Diospyros, Symplac, Magnolia, Victoria, Hightea, Sapindus, Cupania, Eugenia, Eucalyptus, Amygdalus; he suggests that the fruits of the London Clay of Sheppey may belong to the same plant as the leaves found at Alum Bay in the Isle of Wight.

To the Bagshot Sand succeeds the thick mass of sands with intercalated blue clays. In the volcanic districts of the south-west of Scotland and the north-east of Ireland plant-beds are found intercalated between the lava-flows. These also, like the lignites of Bovey Tracey, have been referred to the Miocene period, on the supposed evidence of the fruits, but not of the floret. The specimens which have yet been monographed, Ferns are represented by 17 species and Gymnosperms by 10, though these are not the groups best represented. Gardner speaks of the Bournmouth flora as appearing to consist principally of trees or hard-wooded shrubs, comprising many of the ferns and ligneous species which are now preserved. The higher Eocene strata of England—those above the Bournmouth Beds—are of marine origin, and yield only drifted fruits, principally fir-cones.

**Tertiary**

TAXUS and Podocarpus: Dictyophyllums of about 30 species, several of which have been figured. Among the Dictyophyllums may be mentioned Platania, Acer (?), Quercus (?), Viburnum, Ainos, Magnolia, Cornus (?), Castanea (?), and the nut-tree-like Boehmeria antiqua. The absence of the so-called cinnamon-leaves and the Smilacaceae, which always enter into the composition of Middle Eocene and Oligocene floras, as from dry and moderately dry regions. The Irish strata yield two ferns; 7 Gymnosperms, Cupressus, Cryptomeria, Taxus, Podocarpus, Pinnus (2 species), Tsuga, and another leafy conifer and several leaffy conifers. The most abundant leaf, according to Gardner, does not seem distinct from Celastrephyllum Benedeni, of the Paleocene strata of Gelderland; a water-lily, Nauta, occurs also in Oligocene beds on the Continent; the species of *Macclintokia* (fig. 4) is found both in the Arctic and at Geldenberg. Among the other plants are an alder, an oak, and a yew, and a few ferns.

Leaving these Scottish and Irish deposits of doubtful age, we find in the Hampshire Basin a thick series of fluvial, lacustrine and marine deposits of Lower and Middle Oligocene date. Their flora is still a singularly poor one, though plants have been obtained at many different levels; they perhaps indicate a rather cooler climate than that of the Bournemouth series. Among the more abundant plants are nules of several species of Chara, and drifted fruits and seeds of *Pallonia*. Several species of *Macclintokia*, (now generally referred to *Stratiotes*) and of *Limonopsis* (allied to *Pollenum*) there is little else mixed with these. Other seams are full of the two species of *Athrotaxis*, a Conifer, now confined to Tasmania. Ferns are represented by *Gleichenia*, *Lygodium* and *Cystiodon* Diaeazamum, which last has a very wide distribution in the Northern Hemisphere. Among its allies is *Podocarpus*, a genus which also occurs in the Oligocene of Southern France, and is, like that of the Wetterau, is, like that of the Wetterau, one of the flora of the forests of the forests of Middle Eocene (fig. 4) and a palm-bearing, *Andromeda*, *Cinnamomum*, *Zizyphus*, *Rhiz*, *Viburnum*.

The lignite deposits and pipe-clays of Bovey Tracey in Devon, referred by Heer and Pengelly to the Miocene period, were considered by Gardner to be of the same age as the Bournemouth beds (Middle Eocene). Recent researches show, however, that Heer’s view was more nearly correct. The flora of Bovey is like that of the lignite of the Wetterau, which is either highest Oligocene or lower Miocene. *Saporta* lends itself to a division into two districts, as are a climbing palm, two vines, a magnolia, &c. The common tree at Bovey is *Sequoia Cottis*, which probably grew in profusion in the sheltered valleys of Dartmoor, close to the lake. Above these strata in Great Britain there is a complete breccia, a species of plant ranging upwards into the next fossiliferous division.

Space will not allow us to deal with the numerous scattered deposits which have yielded Tertiary plants. It will be more to the purpose to take distant areas, where the order of the strata is clear, and compare the succession of the floras with that met with in other geographical regions and in other latitudes. For this purpose it will be convenient to take next south and central France, for in that area can be found a series of plant-bearing strata in which is preserved a nearly continuous history of the vegetation from Upper Eocene down to Pleisconic. The account is taken mainly from the writings of Saporta.

The gyposum-deposit of Upper Cretaceous date at Aix in Provence commences this series, and is remarkable for the variety and preservation of its organic remains. Among its Gymnosperms are numerous *Cupressins*, of African affinity belonging to the genera *Calithis* and *Widdringtonia*, and a juniper close to one indigenous in Greece. Fan-plants, the first species of the genus *Nolina* and a tree-fern, like one living in Abyssinia, represent the more peculiar Monotyledons. Among the noticeable Dicotyledons are the *Myrtaceae*, *Proteaceae*, *Laureae*, *Bombax*, the Judas-tree, *Acacia*, *Ailanthus*, while the most plentiful forms are the *Araliaceae*. Willows and poplars, with a few other plants of more temperate regions, are found rare at Aix, and seemingly point to casual introduction from surrounding mountains. In a general way, spiny plants, with stiff branches and dry and coriaceous leaves, dominate the flora, as they now do in Central Africa, to which region on the whole Saporta considers the flora to be most allied.

The succeeding Oligocene floras appear to be more characterized by a gradual replacement of the Eocene species by allied forms, than by any marked change in the aspect of the vegetation. As the Miocene period gave place to a climate more equally and more temperate, the conditions continued without material change into the succeeding Miocene stage. Among the types of vegetation which lost their appearance in Europe during the Oligocene period may be mentioned the *Cheirodendron* and *Ulmus* beds, the *Chamaecyparis* and *Sequoia*, *Taxodium distichum* and *Glyptostrobus europaeus*. The palms include *Sabal haeringiana*, *Regia* and *Helobiea*. Among the *Myrtaceae* several species of *Comphodora* are common. These new-comers are all of American type. Aquatic plants, especially water-lilies, are abundant and varied; the soil-dry *Callitris* and *Widdringtonia* become scarce.

Though we do not propose to deal with the other European localities for Eocene and Oligocene plants, there is one district, that attention should be drawn, on account of the exceptional state of preservation of the specimens. On the Baltic shores of Prussia there is found a quantity of amber, containing remains of insects and plants. This is derived from strata of Oligocene age, and is particularly valuable because it preserves perfectly various soft parts of the plants, which are usually lost in fossil specimens. The tissues, in the preserved jas, as they would be in Canada balsam. The amber yields such things as insects, perfect cutkins of oak, pollen grains and fungi. It enables us to determine accurately orders and genera which are unknown in the fossil state, and it thus aids us in forming a truer idea of the flora of the period than can be formed at any locality where the harder parts alone are recognizable. No doubt this amber flora is still imperfectly known, but it is valuable as giving a good idea of the flora during Oligocene times, of a mixed wood of pine and oak, in which there is a mixture of herbaceous and woody plants, such as would now be found under similar conditions.

The plants of which the floral organs or perfect fruits are preserved include the amber-bearing *Pinus succinifera*, *Smilax*, *Phoenix*, the spike of an arbores, 11 species of oak, 2 of chestnut, a beech, *Urticaceae*, 2 cinnamon and *Trianthox* among the *Lauroaceae*, representatives of the *Cistaceae*, *T erstroemiacae*, *Dilleniaceae* (3 species of *Hibbertia*), *Geraniaceae* (Geranium and *Bowmaniaceae*), *Lonicera*, *Vitex* (2 species), *Umbelliferae, Umbelliferae* (*Chaerophyllum*), *Saxifragaceae* (3 genera), *Hamamelidaceae*, *Rosaceae, Commaracae*, *Ericaceae* (*Andromeda* and *Chelora*), *Myrtaceae* (3 species), *Boraginaceae*, *Sambucus*, *Sambucus* and *Sambucus* (3 species). We here discover for the first time various living families and genera, but there is still a noticeable absence of many of our most prolific existing groups. Whether this deficiency is accidental or real time will show.

The Miocene flora, which succeeds to that just described, is well represented in Europe; but till recently there has been an unfortunate tendency to refer Tertiary floras of all dates to the Miocene period, unless the geological position of the strata was so clear as to be easily for this assignment. Thus plants found in the basalt of Scotland and Ireland were called *Miocene*, and localities in North America even plant-beds of Upper Cretaceous age were referred to the same period. The reason for this was that some of the first Tertiary floras to be examined were certainly Miocene, and, when these plants had been studied, it was considered that these similar assemblages found elsewhere in deposits of doubtful geological age must also be Miocene. For a long time it was not recognized that changes in the marine fauna, on which our geological classification mainly depends, correspond scarcely at all with changes in the land plants. It was not suspected, or the fact was ignored, that the break between Cretaceous and Tertiary—made so conspicuous by striking changes in the aquatic animals—had little or no importance in botanical history. It was not realized that an Upper Cretaceous flora needed critical examination to distinguish it from one of Miocene age, and that the two periods were not characterized by a
sweeping change of generic type, such as took place among the marine invertebrates. It may appear absurd to a geologist that any one could mistake a Cretaceous flora for one of Miocene date, since the marine animals are completely different and the differences are striking. In the case of the plants, however, the large part appeared in Upper Cretaceous times. Few or no extinct types are to be found in these older strata—there is nothing among the plants equivalent to the unmistakably extinct Ammonites, Belemnites, and a multitude of other genera, and we only meet with constant variations in the same genus or family, these variations having seldom any obvious relation to phylogeny.

The Miocene period is unrepresented by any deposits in Great Britain, unless the Bovey lignite should belong to its earliest stage; we will therefore commence with the best known region—that of central Europe and especially of Switzerland, whence a prolific flora has been collected and described by Oswald Heer. The Miocene lacustrine deposits are contained in a number of silted-up lake-basins, which were successively formed and obliterated during the uprise of the Alps and the continuous folding and bending of the earth's crust which was in progress. The strata of the lacustrine sediments, and the other period of similar length; in fact, an analysis of its composition suggests that the Miocene flora of Switzerland must have been both larger and more varied than that now living in the same country. The best known locality for Upper Miocene plants is of course that of Switzerland, where nearly 3000 species of plants, the total number of Miocene plants found in Switzerland being stated to be now over 900. Among the characteristic species of this Miocene flora are the large number of laminae-bearing angiosperms, and the great number of coniferous plants, the gradual decrease in the number of palms and of tropical plants, and the replacement of these latter by Mediterranean or North American forms. According to Heer, the tropical forms in Europe, in the Miocene period, were much more widespread as compared with the present. Among the sub-tropical and temperate plants are allied to forms now living in the temperate zone in North America. Of the 90 species described by Heer, 114 are Cryptogams and 806 flowering plants. Moses has for the most part recognized them as also having been described by Heer, 114 are Cryptogams and 806 flowering plants. Moses has for the most part acceded to the view that the Carboniferous and Triassic plants are more or less similar, in the relations of the two orders of Cryptogams, and the gradual increase in the number of palms and of tropical plants, and the replacement of these latter by Mediterranean or North American forms. According to Heer, the tropical forms in Europe, in the Miocene period, were much more widespread as compared with the present. Among the sub-tropical and temperate plants are allied to forms now living in the temperate zone in North America. Of the 90 species described by Heer, 114 are Cryptogams and 806 flowering plants. Moses has for the most part recognized them as also having been described by Heer.

Within the Arctic circle a large number of Tertiary plants have been collected. These were described by Heer, who referred them to the Miocene period; he recognized, in fact, two periods during which Angiosperms flourished within the Arctic regions, the one Upper Cretaceous, the other Miocene. To this view of the Miocene age of the plant-bearing strata in Greenland and Spitsbergen there are serious objections, which we will again refer to when the flora has been described.
to comprise 2 horsetails, 11 Conifers (including the living Pinus Abies), 2 grasses, a sedge, 2 poplars, a willow, 2 birches, 2 hazels, an elm, a Viburnum, a water-lily, and a lime. Such an assemblage at the present day would suggest a latitude quite 25° farther south; but it should be decided by the combined evidence of the flora, the deposits, and the olive, Alnus, Carpinus, Pagus (4 species), Salix (4 species), Populus (2 species), Platanus, Liquidambar, Planera, Ulmus (2 species), Ficus (2 species), Persoonia, Larus (5 species), Persea, Sassafras, Cinnamomum (5 species), Ginkgo, Diospyros (2 species), Androcarpa, Magnolia (5 species, Acer (3 species), Sapindus, Celasia (2 species), Ilex (4 species), Rhamnus (3 species), Juglans (5 species), Carya (2 species), Rhys., Citrus, Prunus, Cassia (3 species). These plants suggest a cooler climate than that indicated by the vegetations of Mescineum; therefore, the temperature during the period of these deposits being 137°. From various parts of Greenland they now amount to at least 280. Among the plants from Disco, more than a quarter are also found in the Miocene of central Europe.

The plants of Disco, together with the plants of Sibam and Spitsbergen, show clearly that the flora of central Europe was a temperate one in the Miocene, and probably also connected with a temperate flora in the Tertiary. At Britain, the flora was also temperate, and the trees were chiefly oak, beech, poplar, maple, willow, lime, and magnolia. If different deposits are contemporaneous, as is not improbable, there is a distinct change in the flora as we move farther northwards. This suggests that there is little difference of latitude then as now was accompanied by a difference in the flora. But if this process is continuous from latitude to latitude, then we ought not to look for a flora of equivalent age in the warm-temperate Miocene deposits of central Europe. If we accept this theory, the temperate plants of Greenland were contemporaneous with a tropical flora in central Europe. As Mr. Starkie Gardner has pointed out, it does not seem reasonable to assume that the same flora could have ranged then through 40° of latitude; it is more probable that the flora of Europe consisted of a core of temperate species, intermingled with more tropical and arctic species. For example, the temperate flora of central Europe was found in the Miocene, and as the climate became cooler, it became the Miocene temperate flora of central Europe. Mr. Gardner suggests, therefore, that the plant-beds of Greenland and Spitsbergen represent the Miocene temperate flora of central Europe.

At present, the evidence is scarcely sufficient to decide the question, for if this is right, we ought to find within the Arctic circle truly Arctic floras equivalent to the cool Lower Eocene and Miocene periods; but these have not yet been met with.

A steady decrease of temperature marked the Pliocene period throughout Europe, and gradually brought the climatic conditions into correspondence with those now existing, till towards the end of the period neither climate nor physical geography differed greatly from those now existing. Concurrently with this change, the tropical and extinct forms disappeared, and the flora approached more and more nearly to that now existing in the districts where the fossil plants are found, though in the older deposits, at any rate, the geographical distribution within the latter limits was not so marked.

At last, in the latest Pliocene strata (often called "pre-Glacial") we find a flora consisting almost entirely of existing species belonging to the Palearctic regions, and nearly all still living in the country where the fossils are found. This flora, however, is associated with a fauna of large mammals, the majority of which are extinct.

The plants of the Older Pliocene period are unknown in Great Britain, and little known throughout Europe except in central France and the Mediterranean region. The forests of central France during this epoch showed, according to Saporta, a singular admixture of living European species, with trees now characteristic of the Mediterranean and of the temperate zones of Europe, such as Quercus, Picea, Abies, Genista, Alopecurus, and others. The flora was probably not so different from that now existing in the district where the fossils are found. At present, the evidence is insufficient to decide the question, and we ought to find within the Arctic circle truly Arctic floras equivalent to the cool Lower Eocene and Miocene periods; but these have not yet been met with.

The Pliocene period is best known from the Cromer Forest-bed of Norfolk and Suffolk, a fluvo-marine deposit which lies beneath the whole of the Glacial deposits of these counties, and passes downwards into the Crag, many of the animals actually associated with the plants being characteristic of the latter formation. The plants are mainly forest-trees, and seem largely afterwards to have been exterminated by the increasing cold. The plants contained in the Cromer Forest-bed, of which about 150 species have now been determined, fall mainly into the group of forest-trees, and are characteristic of the cooler climates of Europe.

On the Norwich coast another thin plant-bed occurs locally above the forest-bed and immediately beneath the Boulder Clay. This deposit shows no traces of the forest-trees, but is full of remains of oak, beech, and willow and birch; in short, it yields the flora now found within the Arctic circle.

The coming of the Glacial epoch does not appear to have been accompanied by any acclimatization of the plants—the species belonging to temperate Europe were locally exterminated, and Arctic forms took their places. The same Arctic flora reappears in deposits immediately above the highest Boulder Clay, deposits formed after the ice had passed away. These fossil Arctic plants have now been found as far south as Bovey Tracey in Devonshire, where Pengelly and Heer discovered the bear-berry and dwarf birch; London, where also Betula nana occurs; and at Deuben in Saxony, which lies nearly as far south as lat. 50°, but has yielded to Professor Nathorst's researches several Arctic species of willow and saxifrage. The cold period, however, was not continuous, for both in Great Britain and on the continent of Europe, as well as in Canada, it was broken by the recurrence of a milder
;

PALAEOGRAPHY

climate and the reappearance of a flora almost identical with
that now living in the same regions.
This " inter-Glacial "
flora, though so like that now found in the district, has interesting peculiarities. In England, for instance, it includes Acer
monspessulanum, a southern maple which does not now extend
nearer than central Europe, and Cotoneaster Pyracantka; also
Najas graminea and N. minor, both southern forms not now
native of Britain. Brassenia peltata, a water-lily found in the
warmer regions almost throughout the world, except in Europe,
occurs abundantly in north Germany, but not in Great Britain.
Similar inter- Glacial deposits in Tirol contain leaves of Rhododendron ponticum.
Space will not permit us to enter into any full discussion of

Glacial and inter-Glacial periods and the
may have had on the flora. It is evident, howclimatic alternations, such as those just described,
are part of the normal routine that has gone on through all
geological periods, and are not merely confined to the latest,

the recurrence of

influence they
ever, that

if

then such changes must evidently have had great influence on
the evolution and geographical distribution both of species and
of floras.

most general way, to what climatic conditions they point.
seem to find indications of long-period climatic oscillations
in Tertiary times, but none of the sudden invasion of an Arctic
flora, like that which occurred during more recent times.
It
should not be forgotten, however, that an Arctic flora is mainly
distinguishable from a temperate one by its poverty and dwarfed
vegetation, its deciduous leaves and small fruits, rather than
by the occurrence of any characteristic genera or families.
Care f ul and long-continued study would therefore be needed
before we could say of any extinct dwarfed flora that it included
only plants which could withstand Arctic conditions.

PALAEOGRAPHY (Gr. 7ra\ai6s, ancient, and ypa<j>ew, to
write), the science of ancient handwriting acquired from study
of surviving examples.
While epigraphy is the science which
deals with inscriptions

(q.v.) engraved on stone or metal or other
enduring material as memorials for future ages, palaeography
takes cognisance of writings of a literary, economic, or legal
nature written generally with stile, reed or pen, on tablets, rolls
or codices. The boundary, however, between the two sciences
is not always to be exactly defined.
The fact that an inscription
occurs upon a hard material in a fixed position does not necessarily bring it under the head of epigraphy.
Such specimens of

writing as the graffiti or wall-scribblings of Pompeii and ancient

Rome belong as much to the one science as to the other; for
they neither occupy the position of inscriptions set up with
special design as epigraphical monuments, nor are they the
movable written documents with which we connect the idea
But such exceptions only slightly affect the

of palaeography.

broad distinction just

specified.

The scope of this article is to trace the history of Greek and
Latin palaeography from the earliest written documents in
those languages which have survived. In Greek palaeography
we have a subject which is self-contained. The Greek character, in its pure form, was used for one language only; but the
universal study of that language throughout Europe and the
wide diffusion of its literature have been the cause of the
accumulation of Greek MSS. in every centre of learning. The
field of Latin palaeography is much wider, for the Roman
alphabet has made its way into every country of western
Europe, and the study of its various developments and changes
is essential for a proper understanding of the character which,
we

write.

Handwriting,

like every other art, has its different phases
and decay. A particular form of writing
gradually developed, then takes a finished or calligraphic
style and becomes the hand of its period, then deteriorates,
breaks up and disappears, or only drags on an artificial existence, being meanwhile superseded by another style which, either
developed from the older hand or introduced independently,
runs the same course, and in its turn is displaced by a younger
rival.
Thus in the history of Greek writing we see the literary
uncial hand passing from early forms into the calligraphic stage,
and then driven out by the minuscule, which again goes through
a series of important changes. In Latin, the literary capital
and uncial hands give place to the smaller character; and this,
after running its course and developing national characteristics
in the different countries of the West, deteriorates and is superseded almost universally by the Italian hand of the Renaissance.
Bearing in mind these natural changes, it is evident that a
style of writing, once developed, is best at the period when it
is in general use, and that the oldest examples of that period
are the simplest, in which vigour and naturalness of handwriting
are predominant.
On the other hand, the fine execution of a
MS. after the best period of the style has passed cannot conceal
deterioration.
The imitative nature of the calligraphy is
detected both by the general impression on the eye, and by
uncertainty and inconsistencies in the forms of letters. It is
from a failure to keep in mind the natural laws of development and change that early dates, to which they have no
title, have been given to imitative MSS.; and, on the other

of growth, perfection
is


GREEK PAPYRI

PALAEOGRAPHY

...hand, even very ancient examples have been post-dated in an incredible manner.

Down to the time of the introduction of printing, writing ran in two lines—the natural cursive, and the set book-hand which was evolved from it. Cursive writing was essential for the ordinary business of life. MSS. written in the set book-hand filled the place now occupied by printed books, the writing being regular, the lines generally kept even by ruling or other guides, and the texts provided with regular margins. The set book-hand disappeared before the printing press; cursive writing necessarily remains.

In the study of handwriting it is difficult to exaggerate the great and enduring influence which the character of the material employed for receiving the script has had upon the formation of the written letters. The original use of clay by the Babylonians and Assyrians as their writing material was the primary cause of the wedge-shaped symbols which were produced by the natural process of puncturing so stiff and sluggish a substance. The clinging waxen surface of the tablets of the Greeks and Romans superinduced a broken and disconnected style of writing. The comparatively frail surface of papyrus called for a light touch and slenderness built characters. With the introduction of the smooth and hard-surfaced vellum, finer and heavier letters, with marked contrasts of fine and thick strokes, became possible, and thence became the fashion. In the task which lies before us we shall have to deal mainly with MSS. written on the two very different materials, papyrus and vellum, and we shall find how great an extent the general character and the detailed development of Greek and Latin writing, particularly for literary purposes, has been affected by the two materials.

The history of the ancient papyrus roll and of its successor, the medieval vellum codex, and the particulars of the mechanical arrangement of texts and other details appertaining to the evolution of the written book are described in the article MANUSCRIPT. In the present article our attention is confined to the history of the script.

The papyrus period of our subject, as regards literary works, ranges generally from the end of the 4th century B.C. to the 4th century of our era, when the papyrus roll as the vehicle for literature was superseded by the vellum codex. The vellum period extends from the 4th century to the 15th century, when the rise of the art of printing was the doom of the written book. Yet it must not be imagined that there is a hard and fast line separating the papyrus period from the vellum period. In the early centuries of our era there was a transitional period when the use of the two materials overlapped. The employment of vellum for literary purposes began tentatively quite at the beginning of that era; nor did the use of papyrus absolutely cease with the 4th century. But that century marks definitely the period when the change had become generally accepted.

In the case of non-literary documents, written in cursive hands, the papyrus period covers a still wider field. These documents range from the 3rd century B.C. down to the 7th century, and a certain number of examples even extend into the 8th century. The survival of cursive papyrus documents in large numbers is due to the fact that they are chiefly written in Egypt, where papyrus was the common writing material and where climatic conditions ensured their preservation. On the other hand, early cursive documents on vellum are scarce, for it must be borne in mind that, even allowing for the loss of such documents attributable to the perishable nature of that material in the humid climates of Europe, papyrus and waxen tablets were also the usual writing materials of the Greeks and Romans. The importance of the survival of Greek cursive papyri to so late a period is very great, for it enables us to trace the development of the Greek literary minuscule handwriting of the 9th century in a direct line from the cursive script of the papyri centuries earlier.

GREEK WRITING. I.—THE PAPYRI

In no branch of our subject has so great a development been

...since about 1875 as in that of the palaeography of Greek papyri. Before that time our knowledge was very limited. The material was comparatively meagre; and, though its increase was certainly only a matter of time, yet the most sanguine would hardly have dared to foretell the remarkable abundance of documents which the excavations of a few years would bring to light.

The history of Greek writing on papyrus can now be followed with more or less fullness of material for a thousand years. Actual dated examples range from the late years of the 4th century B.C. to the 7th century A.D. We have a fair knowledge of the leading features of the writing of the 3rd and 2nd centuries B.C.; a less perfect acquaintance with those of the 1st century B.C. For the first four centuries of the Christian era there is a fairly continuous series of documents; of the 5th century only a few examples have as yet been recovered, but there is an abundance of material for the 6th and early 7th centuries. Thus it will be seen that, while for some periods we may be justified in drawing certain conclusions and laying down certain rules, for others we are still in an imperfect state of knowledge. But our knowledge will no doubt almost yearly become more exact, as fresh material is brought to light from the excavations which are now continually proceeding; and those periods in which the lack of papyri breaks the chain of evidence will sooner or later be as fully represented as the rest. The material certainly lies buried in the sands; it is our misfortune that the exact sites have not yet been struck.

The first discovery of Greek papyri was made in Europe in 1752, when the excavations on the site of Herculanum yielded a number of charred rolls, which proved to be of a literary character. All subsequent discoveries we owe to Egypt; and it is to be observed that the papyri which are found in that country have come down to us under different conditions. Some, generally of a literary nature, were carefully deposited with the bodies of their owners in the tomb with the express intention of being preserved; hence such MSS. in several instances have come to our hands in fairly perfect condition. On the other hand, by far the larger number of those recently brought to light have been found on the sites of towns and villages, particularly in the district of the Fayûm, where they had been either accidentally lost or purposely thrown aside as of no value, or had even been used up as material for other purposes besides their original one. These are consequently for the most part in an imperfect and even fragmentary condition, although not a few of them have proved to be of the highest palaeographical and literary importance.

The date of the first find of Greek papyri in Egypt was in 1778, when some forty or fifty rolls were discovered by some native diggers, who, however, kept only one of them. After this scarcely anything appeared until the year 1820, when was found on the site of the Serapeum at Memphis, as it was reported, a group of documents of the 2nd century B.C. Then followed a fruitful period, when several important literary papyri were brought in 1831, by the Archduke Rainer, containing the roll containing the Lycophron and other orations of Hypereides; in 1849 and 1850, the Harris Homer, bk. xviii. of the Iliad; in 1847, the roll containing the Iliad; in 1851, the roll containing the Iliad; in 1856, the Funeral Oration of Hypereides. But the great bulk of the Greek papyri from Egypt is the result of excavations undertaken during the last quarter of the 19th century and down to the present day. Within this time four very important discoveries of documents in large quantities have taken place. In 1877 a great mass of papyri was found on the site of Arsinóe in the Fayûm, being chiefly of a non-literary nature, and unfortunately in a very fragmentary state; they are also late in date, being of the Byzantine period. The greater number passed into the possession of the Archduke Rainer, and are now at Vienna; the rest are divided between London, Oxford, Paris and Berlin. After an interval this find was followed by the discovery in 1892, in the same neighbourhood, and chiefly on the site of a village named Nesioussa, of an extensive series of documents of the Roman period,
ranging from the 1st century to the middle of the 3rd century. These papyri, being of an earlier date and in better condition than the Aristeides collection, are consequently of greater palaeographical value. Most of them are now in Berlin; many are in the British Museum; and some are at Vienna, Geneva, and elsewhere. The third and fourth great finds, and the most important of all, were made by Messrs Grenfell and Hunt when excavating, in the seasons 1896–1897 and 1905–1906, for the Egypt Exploration Fund, at Behnesa, the ancient Oxyrhynchus.

Thousands of papyri were here recovered, including, among the non-literary material, a number of rolls in good condition, and comprising also a great store of fragments of literary works, among which occur the now well-known “Logia,” or “Sayings of Our Lord,” and fragments of the Scriptures, and in some instances of not inconsiderable portions of the writings of various classical authors. This great collection ranges in date from the 2nd century B.C. to the 7th century A.D.; but in what proportion the documents fall to the several centuries cannot be determined until the series of volumes in which they are to be described for the Graeco-Roman branch of the Egypt Exploration Fund shall have made some substantial progress.

These four great collections of miscellaneous documents have been supplemented by finds, here and there, which fit into their places, first and to make more complete the chronological series. Such are the correspondence of a Roman officer named Abinnaeus, of the middle of the 4th century, shared between the British Museum and the library of Geneva in the year 1892; a miscellaneous collection, ranging from the 2nd century B.C. to the 3rd or 4th century A.D., acquired for the Egypt Exploration Fund and published by that society (Pauly’s宇文匡 and their Papyri, 1900); another collection obtained for the same society from the cartonnage of mummy-cases dating back to the 3rd century B.C. (The Hiebol Papyri, 1906); and a series recovered from excavations at Tebtunis for the University of California (The Tebtunis Papyri, 1903, 1906), generally of the 2nd century B.C. But of these lesser groups by far the most interesting is that which Mr Finders Petrie excavated, in 1883–1895, from a set of mummy-cases found in the necropolis of the village of Gurob in the Fayum. In the manufacture of these coffins numbers of inscribed papyri had been employed. The fragments thus recovered proved to be of some of the most valuable documents for the history of Greek palaeography hitherto found, supplying us with examples of writing of the 3rd century B.C. in fairly ample numbers, and thus carrying back our fuller knowledge of the subject to a period which up to that time had remained almost a blank. Besides miscellaneous documents, there are included the remains of registers of wills entered up from time to time by different scribes, and thus affording a variety of handwritings for study; and, further, the value of the collection is enhanced by the presence of fragments of the Phaedo and Laches of Plato, and of the lost Antiope of Euripides and of other classical works.

The last decade of the 19th century was also distinguished by the discovery of several literary works of the first importance, inscribed on papyri which had been deposited with the dead, and had thus remained in a fairly perfect condition. In 1889 the trustees of the British Museum acquired a copy of the lost Αθεσίδων Δολοφές of Aristotle—a papyrus of the mime of the powdered hairs, and a portion of the oration of Hyperides against Philippides; and in 1896 they had the further good fortune to secure a papyrus containing considerable portions of the odes of Bacchylides, the contemporary of Pindar. And to the series of the orations of Hyperides the Louvre was enabled to add, in 1892, a MS. of the greater part of the oration against Athenogenes.

But the most valuable discovery, from a palaeographical point of view, took place in the present century. In 1902 a papyrus roll containing the greater portion of the Persae, a lyrical composition of Timotheus of Miletus, was found at Abusir, near Memphis, and is now at Berlin. It is written in a large hand of a style which had hitherto been known from a document at Vienna entitled the "Curse of Artemisia," and assigned to the early part of the 3rd century B.C.; and from one or two other insignificant scraps. The new papyrus, however, appears to be even older, and may certainly be placed in the later years of the 4th century B.C.: the most ancient extant literary MS. in the Greek tongue. The ascription of this papyrus to the 4th century B.C. has received confirmation from the welcome discovery, in 1906, at Elephantine, of a document (a marriage contract) of the year 312–310 B.C., which is written in the same style of book-hand characters (Aegypt. Urkunden d. kgl. Museen in Berlin, Elephantine Papyri, 1907). Of quite recent date also is the recovery of a considerable part of a commentary on the Theaetetus of Plato, written in a fine uncial hand of the 2nd century, now in Berlin. Considerable fragments also, from the Paeans of Pindar of the 1st or 2nd century; a papyrus containing an historical work attributed to Theopompos or Cratinus, perhaps, of the early 3rd century; a copy of Plato's Symposium of the same period; and a portion of the Panegyrics of Isocrates, written in an uncial hand of the 2nd century, are printed in Part V. of the Oxyrhynchus Papyri. Further, many leaves of a papyrus codex containing fragments of four comedies of Menander were found in 1905 at Kom Nakhib near the Fayum.

The recovery of so many great classical works within a few years may be accepted as an earnest of further finds of the same nature, now that excavations are being carried on systematically in Egypt.

From a study of the material thus placed at our disposal certain conclusions have been arrived at which satisfy us that the periodical changes which passed over the character of Greek writing as practised in Egypt coincide pretty nearly with the changes in the political administration of the country. The period of the rule of the Ptolemies from 323 to 30 B.C. has, in general, its own style of writing, which we recognize as the Ptolemaic; the period of Roman supremacy, beginning with the conquest of Augustus and ending with the reorganization of the empire by Dioecletian in A.D. 284, is accompanied by a characteristic Roman hand; and with the change of administration which placed Egypt under the Byzantine division of the empire, and lasted down to the time of the Arab conquest in A.D. 642, there is a corresponding change to the Byzantine class of writing. These changes must obviously be attributed to the influence of the official handwritings of the time. A change of government naturally led to a change of the officials employed, and with the change of officials would naturally follow a change in the style of production of official documents. In illustration of this view, it is enough to call to mind the instances of such variations to be met with in the history of the palaeography of medieval Europe, due in the same way to political causes. It is interesting, too, to observe that in our own time the teaching in schools of a particular type of handwriting which finds favour in clerical examinations for the public service has not been without its influence on the general handwriting of the people.

Classifying, then, the writing of the papyri into the three groups—the Ptolemaic, the Roman, and the Byzantine—the next step is to determine, by a closer examination of the documents, the changes which characterize the several centuries traversed by those groups. In doing this, we cannot apply the exact terms which are employed in describing the MSS. of the middle ages. We have to do with writing which has not yet been cast in the official literary moulds of the later empire. It is therefore found necessary, as well as convenient, to divide the papyri simply into two series, representative of their contents and not of their style of production—namely literary papyri and non-literary papyri. Neither series, however, is to be remembered, has a style of writing peculiar to itself. While the extant literary works are, as a rule, written with more or less formality, no doubt by professional scribes for the bookmarket, not a few of even the more valuable of them are copies in the ordinary cursive hands of the day. Conversely, while we find non-literary documents generally written in ordinary cursive hands, whether by official scribes or by private individuals, yet occasionally we meet with one produced in the formal style more proper to literary examples. Again, while applying to
particular letters in papyri such technical terms as capitals, or uncials, or minuscules, we cannot convey by those terms the exact ideas which we convey when thus describing the individual letters of medieval manuscripts. For the letters of the papyrus period were not cast in finished moulds, while the uncial writing and the minuscule writing of the middle ages were settled literary hands. As will presently be seen, the early medieval uncial hand of the vellum codices developed directly from the literary writing of the papyri; the minuscule book-hand of the 9th century was a new type moulded from the cursive into a fixed literary style.

Necessarily, the non-literary papyri are much more numerous than the literary documents, and present a much greater variety of handwriting, being in fact the result of the daily transactions of ordinary life; and how very widespread was the knowledge of writing among the Greek-speaking population of Egypt is sufficiently testified by the surviving examples, coming as they do from the hands of all sorts and conditions of men. We will first examine these specimens of the current handwriting of the day before passing to the review of the more or less artificial book-writing of the literary papyri.

Non-Literary, Cursive, Hands.—As already stated, the oldest material for the study of Greek cursive writing is chiefly contributed by the papyri discovered at Gurob. Among them are not only the fragments of official registers, which have been mentioned, but also a large number of miscellaneous documents relating to private affairs, and in various hands of the 3rd century and early 2nd century B.C. The non-literary cursive papyri bear actual dates ranging from 270 to 186 B.C. But the discovery (1906) of papyri at Elephantine takes our dated series of cursive documents back to 285-284 B.C.; and in this collection also is the oldest dated Greek document yet found—the marriage contract of the year 311-310 B.C., already mentioned. In this instance, however, the writing is not cursive, but of the literary type.

The leading characteristic of Greek cursive writing of the 3rd century B.C. is its strength and facility. While it may not compare with some later styles in the precise formation of particular letters, yet its freedom and spontaneity lend it a particular charm and please the eye, very much in the same way that a scholar's practised and unconscious handwriting of a good type is more attractive than the more exact formality of a clerk's hand. The letters generally are widely spread and shallow, and, particularly in the official hands, they are linked together with horizontal connecting strokes to such an extent that the text has almost the appearance of depending from a continuous horizontal line. The extreme shallowness or flatness of many of the letters is very striking. A significant indication of the antiquity of Greek cursive writing is found in connexion with the letter alpha, which is, even at this early period, in one of its forms reduced to a mere angle or wedge.

A few lines from an official order (fig. 1) of the year 250 B.C. will serve to convey an idea of the trained cursive style of this century:

![Fig. 1.—Official Order, 250 B.C.](image)

As a contrast to this excellent hand, we give a facsimile of a section from a roughly written letter from a land steward to his employer, of about the same date:

![Fig. 2.—Letter of a Land Steward, 3rd century B.C.](image)

Here there is none of the linking of the letters which is seen in the other example: every letter stands distinct. But while the individual letters are clumsily written, the same laws govern their formation as in the other document. The shallow, wide-spread mu, the cursive nu, the small theta, omicron, and rho, are repeated. Here also is seen the tau, with its horizontal stroke confined to the left of the vertical instead of crossing it, and the undeveloped omega, which has the appearance of being clipped—both forms being characteristic of the 3rd century B.C.

The trained clerical hands of the 2nd century B.C. (fig. 3) differ generally from those of the earlier century in a more perfect and less cursive formation, the older shallow type gradually disappearing, and the linking of letters by horizontal strokes being less continuous. But the Ptolemaic character marks the handwriting well through the century; and it is only towards the close of that period and as the next century is entered, that the hand begins to give way and to lose altogether its linked style and the peculiar crispness of the strokes which give it its distinctive appearance. The cursive hand in its best style (e.g. N. et Extr. pl. xxvii.) is very graceful and exact:

![Fig. 3.—Petition, 163-162 B.C.](image)

Towards the end of the Ptolemaic period material greatly fails. There are very few extant cursive documents between the years 80 and 20 B.C. But marks of decadence already appear in the examples of the beginning of the 1st century B.C. The general character of the writing becomes slack, and the forms of individual letters are less exact. These imperfections prepare us for the great change which was to follow.

With the Roman period comes roundness of style, in strong contrast to the stiffness and rigid linking of the Ptolemaic hand. Curves take the place of straight strokes in the individual letters, and even ligatures are formed in plant sweeps of the pen. This transition from the stiff to the flexible finds something of a parallel in the development of the curving and flexible English charterhand of the 14th century from the rigid hand of the 13th century; following, it would seem, the natural law
of relaxation. Roundness of style, then, is characteristic of Greek cursive writing in the papyri of the first three centuries of the Christian era, however much individual hands, or groups of hands, might vary among themselves.

A specimen (fig. 4) of cursive writing of the general Roman type is selected from a papyrus (Brit. Mus. No. cxiii.) which is of more than usual interest, as it is on the verso side of the rolls of which it is composed that the text of Aristotle's Constitution of Athens has been transcribed. It contains the farming accounts of the bailiff of Epimachus, son of Polydeuces, the owner of an estate in the nome of Hermopolis in the 4th and 10th years of the reign of Vespasian, that is A.D. 78-79:

Fig. 4.—Farm Accounts, A.D. 78-79.

(εγοὺς εὐθείανον α—
κείσπεσαίονος σεβάστων—
πανανοὺς μένος χ—
τὸ δὲ αὐτοῦ επωμάξου ε—)

In the second half of the 1st century two styles of handwriting predominate in the cursive papyri. There is the clear and flowing hand, which may be termed the ordinary writing; and there is also a small and very cursive style which appears in private correspondence and in legal contracts.

The 2nd century follows on the same lines as the 1st century; but with the 3rd century decadence sets in; the writing begins to slope, and grows larger and rougher and tends to exaggeration.

This exaggeration of the writing of the later Roman period leads the way to the pedantic exaggeration and formalism characteristic of the Byzantine period. In this period the general style of writing is on a larger scale than in the Roman; exaggeration in the size of certain letters marks the progress of the 4th century. Material is wanting for full illustration of the changes effected in the 5th century; but the papyri of the 6th century show a further advance in formalism, the common style being upright and compressed and full of flourishes. In the 7th century the hand assumes a sloping style, which always seems to accompany decadence, and grows very irregular and straggling. A specimen of the fully developed Byzantine hand of a legal type is here shown in a few lines from a lease of a farm (fig. 5) in the 6th century (Brit. Mus. pap. cxiii. 3):

Fig. 5.—Lease of a Farm, 6th century.

In the long range covered by the Greek papyri the formation of individual letters necessarily varied under different influences; but in not a few instances the original shapes were remarkably maintained. From those which thus remained conservative it is rash to attempt to draw conclusions as to the precise age of the several documents in which they occur. On the other hand, there are some which at certain periods adopted shapes which were in vogue for a limited time and then disappeared, never to be resumed. Such forms can very properly be regarded as sure guides to the palaeographer in assigning dates. We may therefore take a brief survey of the Greek cursive alphabet of the papyri and note some of the peculiarities of individual letters. The incipient form of the alpha which gradually developed into the minuscule letter of the middle ages may be traced back to the Ptolemaic documents of the 2nd century B.C., but the more cursive letter, which was a simple acute angle, representing only two of the three strokes of which the primitive letter was composed, was characteristic of the 3rd century B.C., and seems to have gone out of use within the Ptolemaic period. The development of the cursive beta is interesting. At the very beginning we find two forms in use: the primitive capital letter and a cursive shape somewhat resembling a small n, being in fact an imperfectly written B in which the bows are slurred. This form lasted through the Ptolemaic period. Then arose the natural tendency to reverse the strokes and to form the letter on the principle of w; but still the capital letter also continued in use, so that through the Roman and Byzantine periods the n-shape and the B-shape run on side by side. Analogously the letter kappa, formed on somewhat the same lines as the beta, runs a similar course in developing a cursive u-shaped form by the side of the primitive capital. Delta remained fairly true to its primitive form until the Byzantine period, when the elongation of the head into a flourished led to the minuscule letter which is familiar to us in the medieval and modern alphabet. Epsilon, the most frequently recurring letter in Greek texts, departs less from its original rounded uncial form that might have been expected. Frequent and varied as its cursive formations are, yet the original shape is seldom quite disguised, the variations almost in all instances arising from the devices of the scribe to dispose swiftly and conveniently of the cross-bar by incorporating it with the rest of the letter. The tendency to curtail the second vertical limb of eta, leading eventually to the B-shape, is in evidence from the first. But in the development of this letter we have one of the instances of temporary forms which lasted only within a fixed period. In the 1st century, side by side with the more usual formal form, there appears a modification of it, somewhat resembling the contemporary upsilon, consisting of a shallow horizontal curve with a vertical limb slightly turned in at the foot. Its development from the original H is evident: the first vertical limb is slurred, and survives only in the beginning of the horizontal curve, while the cross-bar and the second vertical are combined in the rest of the letter. This form was in general use from the middle of the 1st to the middle of the 2nd century, becoming less common after about A.D. 160, and practically disappearing about A.D. 200. The letters formed wholly or in part by circles or loops, theta, omicron, rho, phi, in the earlier centuries have such circles or loops of a small size. Just as there is an analogy between beta and kappa in their developments, as already noticed, so also do mu and pi advance on somewhat similar lines. From the earliest time there is a remarkable difference between the broad shallow forms of the two letters in the 3rd century B.C., and particularly when they adopt the form of a convex stroke the likeness is very close; and again, in both Roman and Byzantine periods an n-shaped development appears with the forms of both letters. There is also one phase in the development of sigma which affords a useful criterion for
fixing the date of documents within a fixed limit of time. In the Ptolemaic period the letter, always of the C-form, is upright, with a flattened horizontal head; in the Roman period a tendency sets in to curve the head, and in the course of the 1st century, by the side of the old stiffer form of the letter, another more cursive one appears, in which the head is drawn down more and more in a curve, C C. This form is in common use from the latter part of the 1st century to the beginning of the 3rd century. The cursive form of tau, in which the horizontal stroke is kept to the left of the vertical limb, without crossing it, is one of the early shapes of the letter. The formation of the letter Xi in three distinct horizontal strokes is characteristic of the Ptolemaic period, as distinguished from the later type of letter in which the bars are more or less connected. Lastly, the early Ptolemaic form of the ω-shaped omega is noticeable from having its second curve undeveloped, the letter having the appearance of being clipped.

**Literary Hands.**—Literary papyri written in book-hands, distinct from the cursive writing which has been under consideration (and in which literary works were also occasionally written), may be divided into two classes: those which were produced by skilled scribes, and therefore presumably for the market, and those which were written less elegantly, but still in literary hand, and were probably copied by or for scholars for their own use. Standing at the head of all, and holding that rank as the only literary papyri of any extent which may be placed in the 4th century B.C., is the famous lyrical work of Timotheus of Mileto, entitled the *Persae*, which has already been referred to and of which a section of a few lines is here reproduced:

![Fig. 6.—The Persae of Timotheus, late 4th century B.C.](image)

The general breadth of the square letters, the smallness of the letters composed of circles and loops, and the particular formation of such letters as π and the clipped omega, are repeated. But the approach also of many of the letters to the lapidary capital forms, like those in the papyrus of Timotheus, is to be remarked, such as the precisely shaped αλφα, and the ειςion in many instances made square with a long head-stroke. This mixture of forms seems to indicate an advance in the development of the book-hand of the 3rd century B.C., as contrasted with the archaic style of the older Timotheus.

Of the 2nd century B.C. there are extant only two papyri of literary works written in the formal book-hand, and both are now preserved in the Louvre. The one, a dialectical treatise containing quotations from classical authors, has long been known. The other is the oration of Hypereides against Athenogenes, which is an acquisition of comparatively recent date. The dialectical treatise must belong to the first half of the century, as there is on the verso side of the papyrus writing subsequently added in the year 160 B.C. The period of the Hypereides cannot be so closely defined; but the existence on the verso of later demotic writing, said to be of the Ptolemaic time, affords a limit, and the MS. has been accordingly placed in the second half of the century. While the writing of the earlier papyrus is of a light and rather sloping character, that of the Hypereides is firm and square and upright.

Passing to the 1st century B.C., the papyri which have been recovered from the ashes of Herculaneum come into account.
PALAEOGRAPHY

562

Many of them, the texts of which are of a philosophical nature, are written in literary hands, and are conjectured to have possibly formed part of the library of their author, the philosopher Philodemus; they are therefore placed about the middle of the century. To the same time are assigned the remains of a roll containing the oration of Hyperides against Philippides and the third Epistle of Demosthenes (Brit. Mus. pap. cxxiii., cxxiv.). But the most important addition to the period is the handsomely written papyrus containing the poems of Bacchylides (fig. 8), which retains in the forms of the letters much of the character of the Ptolemaic style, although for other reasons it can hardly be placed earlier than about the middle of the century:

\[
\begin{align*}
\text{Fig. 8.—Bacchylides, 1st century B.C.}
\end{align*}
\]

With the latter half of the 1st century B.C. we quit the Ptolemaic period and pass to the consideration of the literary papyri of the Roman period; and it is especially in this latter period that our extended knowledge, acquired from recent discoveries, has led to the modification of views formerly held with regard to the dates to be attributed to certain important literary MSS.

As in the case of non-literary documents, the literary writing of the Roman period differs from that of the Ptolemaic in adopting rounded forms and greater uniformity in the size of the letters.

Just on the threshold of the Roman period, near the end of the 1st century B.C., stands a fragmentary papyrus of the last two books of the Iliad, now in the British Museum (pap. cxxviii.), which is of sufficient extent to be noted. Then, emerging on the Christian era, we come upon a fine surviving specimen of literary writing, which we have satisfactory reason for placing near the beginning of the 1st century. It is a fragment of the third book of the Odyssey (fig. 9), the writing of which closely resembles that of an official document (Brit. Mus. pap. ccclv.), which happens to be written in a formal literary hand, and which from internal evidence can be dated within a few years of the close of the 1st century B.C. There can be no hesitation, therefore, in grouping the Odyssey with that document. The contrast between the round Roman style and the stiff and firm Ptolemaic hands is here well shown in the facsimiles from this papyrus (fig. 9) and the Phaedo and Bacchylides:

\[
\begin{align*}
\text{Fig. 9.—The Odyssey, beginning of 1st century.}
\end{align*}
\]

In a similar style of writing are two fragments of Hesiodic poems recently published, with facsimiles, in the Sitzungsberichte (1900, p. 839) of the Berlin Academy. The earliest of the two, now at Strassburg, may be assigned to the first half of the 1st century; the other, at Berlin, appears to be of the 2nd century.

At this point two MSS. come into the series, in regard to which there is now held to be reason for revising views formerly entertained. The papyrus known as the Harris Homer (Brit. Mus. pap. xvii.), containing portions of the eighteenth book of the Iliad, which was formerly placed in the 1st century B.C., is now thought to have been brought down to a later date, and should be rather assigned to the 1st century of the Christian era. The great papyrus, too, of Hypereides, containing his orations against Demosthenes and for Lyceophon and Euxenippus, which has been commonly placed also in the 1st century B.C., and by some even earlier, is now adjudged to belong to the latter part of the 1st century A.D.

Within the 1st century also is placed a papyrus of great literary interest, containing the mimes of the Alexandrian writer Herodas, which was discovered a few years ago and is now in the British Museum. The writing of this MS. differs from the usual type of literary hand, being a rough and ill-formed uncial, inscribed on narrow, and therefore inexpensive, papyrus; and if the roll were written for the market, it was a cheap copy, if indeed it was not made for private use. Of the same period is a papyrus of Isocrates, De pace (Brit. Mus. pap. cxxvii.), written in two hands, the one more clerical than the other; and two papyri of Homer, Iliad, iii.–iv. (Brit. Mus. pap. cxxvi.), and Iliad, xiii.–xiv. (Brit. Mus. pap. cccxxxi.), the first in a rough uneducated hand, but the latter a fine specimen of uncial writing. To about this period also is the Oxyrhynchus Pindar to be attributed, that is to the close of the 1st or beginning of the 2nd century. Then follows another famous papyrus, the Bankes Homer, containing the last book of the Iliad, which belongs to the 2nd century and is also written in a careful style of uncial writing. To these is to be added the beautiful papyrus at Berlin, containing a commentary on the Theaetetus of Plato, written in delicately formed uncialis of excellent type of the 2nd century; and of the same age is the Panegyricus of Isocrates from Oxyrhynchus, in a round uncial hand. Three important papyri of the Iliad, written in large round uncialis, of the 2nd century, are noticed below.

With regard to the later literary works on papyri that have been recovered, the period which they occupy is somewhat uncertain. The following are, however, placed in the 3rd century, during which a sloping literary hand seems to have been developed, curiously anticipating a similar change which took place in the course of development of the uncial writing of the vellum MSS., the upright hand of the 4th to 6th centuries being followed by a sloping hand in the 7th and 8th centuries: a MS. now in the British Museum, of portions of bks. ii.–iv. of the Iliad, written on eighteen leaves of papyrus, put together in book-form, but inscribed on only one side; on the verso of some of the leaves is a short grammatical treatise attributed to Tryphon: portion of Plauto’s Leuca (Ox. pap. xxiii.); a papyrus of Isocrates, Nicomachen, now at Marseilles: a fragment of Ezekiel, in book-form, in the Bodleian Library: a fragment of the “Shepherd” of Hermas at Berlin: and a fragment of Julius Africanus, the Hellenica of Theopompos or Cratippus, and the Symposium of Plato, all found at Oxyrhynchus.
Of the 3rd century also are some fragments which are palaeographically of interest, as they are written neither in the recognized literary hand nor in simple cursive, but in cursive characters moulded and adapted in a set form for literary use——thus anticipating the early stages of the development of the minuscule book-hand of the 9th century from the cursive writing of that time.

With the 3rd century the literary hand on papyrus appears to lose most of its importance. We are within measurable distance of the age of vellum, and of the formal uncial writing of the vellum MSS. which is found in some existing examples of the 4th century and in more abundant numbers of the 5th century. We have now to see how the connexion can be established between the literary handwriting of the papyri and the firmer and heavier literary uncial writing of the vellum codices. The literary hands on papyrus which have been reviewed above are distinctly of the style inscribed with a light touch most suitable to the comparatively frail material of papyrus. In the BankeS Homer, however, one may detect some indication of the fullness that characterizes the vellum uncial writing. But it now appears that a larger and rounder hand was also employed on papyrus at least as early as the 1st century. In proof of this we are able to cite a non-literary document (fig. 10) bearing an actual date, which happens to be written in characters that, exclusive of certain less formally-made letters, are of a large uncial literary type. This writing, though not actually of the finished style familiar to us in the early vellum MSS., yet resembles it so generally that it may be assumed, almost as a certainty, that there was in the 1st century a full literary uncial hand formed on this pattern, which was the direct ancestor of the vellum uncial. The tendency to employ at this period a calligraphic style, as seen in the fragments of the Odyssey and one of the Hesiodic poems mentioned above, supports this assumption. The document now referred to is a deed of sale written in the seventh year of Domitian, A.D. 88 (Brit. Mus. pap. cxlii.). The letters still retaining a cursive element are alpha, upsilon, and in some instances epsilon.

As evidence in support of this view that the uncial hand of the vellum MSS. is to be traced back to the period of the document just quoted, we have the important papyrus found by Mr Flanders Petrie at Hawara in Egypt, and now in the Bodleian Library, which contains a portion of the second book of the Iliad. The writing is of the large uncial type under consideration; and there is now full reason for assigning it to the 2nd century at latest. Before the discovery of the document of the year 88 there was nothing to give a clue to the real period of the Homer; and now the date which has been suggested is corroborated by a fragment of papyrus from Oxyrhynchus inscribed with some lines from the same book of the Iliad (fig. 11) in the same large uncial type (Ox. Pap. vol. i. no. 20, pl. v.). In this latter instance there can be no question of the early date of the writing as on the verso of the papyrus accounts of the end of the 2nd century or of the beginning of the 3rd century have been subsequently added. Yet a third example of the same character has more recently been found at Tebtunis (Tebt. Pap. vol. ii. no. 255, pl. i.): a gain a considerable fragment of the second book of the Iliad.

Thus, then, in the 1st and 2nd centuries there was in use a large uncial hand which was evidently the forerunner of the literary uncial hand of the early vellum codices. It is also to be noted that the literary examples just mentioned are MSS. of Homer; and hence one is tempted to suggest that, as in the production of sumptuous copies on papyrus of a work of such universal popularity and veneration as the Iliad this large and handsome uncial was specially employed, so also the use of a similar type for the early vellum copies of the sacred text of the Scriptures naturally followed.

GREEK WRITING. II.—THE VELLUM CODICES

Uncial Writing.—It has been shown above how a round uncial hand had been developing in Greek writing on papyrus during the early centuries of the Christian era, and how even as early as the 2nd century a well-formed uncial script was in use, at least for sumptuous copies of so great and popular an author as Homer. We have now to describe the uncial hand as it appears in Greek MSS. written on vellum. This harder and firmer and smoother material afforded to the scribes better scope for a calligraphic style hardly possible on papyrus. With the introduction of the uncial hand for literature the characters received the fixed and settled forms which are the name of uncial is more exactly attached to than to the fluctuating letters of the early papyri. The term uncial has been borrowed from the nomenclature of Latin palaeography and applied to Greek writing of the larger type, to distinguish it from the minuscule or smaller character which succeeded it in vellum MSS. of the 9th century. In Latin majuscule writing there exist both capitals and uncials, each class distinct. In Greek MSS. pure capital-letter writing was never employed (except occasionally for ornamental titles at a late time). As distinguished from the square capitals of inscriptions, Greek uncial writing has certain rounded letters, as a, e, c, o, modifications in others, and some letters extending above or below the line.

It is not probable that vellum codices were in ordinary use earlier than the 4th century; and it is in codices of that age that the handsomest calligraphic uncials above referred to was developed. A few years ago the 4th century was the earliest limit to which palaeographers had dared to carry back any ancient vellum codex inscribed in uncials. But the recovery of the Homeric papyri written in the large uncials of the 2nd century has led to a revision of former views on the date of one early vellum MS. in particular. This MS. is the fragmentary Homer of the Ambrosian Library at Milan, consisting of some fifty pieces of vellum cut out of the original codex for the sake of the pictures which they contain; and of all the text that has survived is that which happened to be on the back of the pictures. The Ambrosian Homer has hitherto been generally placed in the 5th century, and the difference of the style of the writing from that of the usual calligraphic type of uncial MSS. of that time, which had been remarked, was thought rather to indicate inferiority in age. But the similarity of the character of the writing (taller and more slender than the usual in vellum codices) and of the large uncials of the papyrus Homers of the 2nd century from Hawara and Oxyrhynchus and Tebtunis is so striking that the

1 St Jerome's often quoted words, "uncialibus, ut vulgo alium litteram," in his preface to the book of Job, have never been explained satisfactorily. Of the character referred to as "uncial" there is no question; but the derivation of the term is not settled.
Ambrosian Homer must be classed with them. Hence it is now held that that MS. may certainly be as early as the 3rd century. But, as that century was still within the period when papyrus was the general vehicle for Greek literature, it may be asked why that material should not in this instance also have been used. The answer may fairly be ventured that vellum was certainly a better material to receive the illustrative paintings, and on that account was employed. The Ambrosian Homer may therefore be regarded as a most interesting link between the papyrus uncial of the 2nd century and the vellum uncial of the 4th and 5th centuries.

With the introduction, then, of vellum as the general writing material, the uncial characters entered on a new phase. The light touch and delicate forms so characteristic of calligraphy on papyrus gave place to a rounder and stronger hand, in which the contrast of fine hair-lines and thickened down-strokes adds so conspicuously to the beauty of the writing of early MSS. on vellum. And here it may be remarked, with respect to the attribution to particular periods of these early examples, that we are not altogether on firm ground. Internal evidence, such, for example, as the presence of the Eusebian Canons in a MS. of the Gospel, assists us in fixing a limit of age, but when there is no such support the dating of these early MSS. must be more or less conjectural. It is not till the beginning of the 6th century that we meet with an uncial MS. which can be approximately dated; and, taking this as a standard of comparison, we are enabled to distinguish those which undoubtedly have the appearance of greater age and to arrange them in some sort of chronological order. But these codices are too few in number to afford material in sufficient quantity for training the eye by familiarity with a variety of hands of any one period—the only method which can give entirely trustworthy results.

Among the earliest examples of vellum uncial MSS. are the three famous codices of the Bible. Of these, the most ancient, the Codex Vaticanus, is probably of the 4th century. The writing must, in its original condition, have been very perfect as a specimen of penmanship; but nearly the whole of the text has been traced over by a later hand, perhaps in the 10th or 11th century, and only such words or letters as were rejected as readings have been left untouched. Written in triple columns, in letters of uniform size, without enlarged initial letters to mark even the beginnings of books, the MS. has all the simplicity of extreme antiquity (Pal. Soc. pl. 104). The Codex Sinaiticus (Pal. Soc. pl. 105) has also the same marks of age, and is judged by its discoverer, Tischendorf, to be even more ancient than the Vatican MS. In this, however, a comparison of the writing of the two MSS. leads to the conclusion that he was mistaken. The writing of the Codex Sinaiticus is not so pure as that of the other MS., and, if that is a criterion of age, the Vatican MS. holds the first place. In one particular the Codex Sinaiticus has been thought to approach in form to its possible archetype on papyrus. It is written with four columns to a page, the open book thus presenting eight columns in sequence, and recalling the long line of columns on an open roll. With regard to such general outward resemblances between the later papyrus literary rolls and the early vellum uncial MSS., we may cite such papyri as the Berlin commentary on the Theaetetus of Plato of the 2nd century and the Oxyrhynchus fragment of Julius Africanus of the 3rd century as forerunners of the style in which the two great codices here mentioned were cast.

The Codex Alexandrinus (fig. 12) is placed in the middle of the 5th century. Here we have an advance on the style of the other two codices. The MS. is written in double columns only, and enlarged letters stand at the beginning of paragraphs. But yet the writing is generally more elegant than that of the Codex Sinaiticus. Examining these MSS. with a view to ascertain the rules which guided the scribes in their work, we find simplicity and regularity the leading features; the round letters formed in symmetrical curves; $\epsilon$ and $\zeta$, $\eta$ and $\omicron$, finishing off in a hair-line sometimes thickened at the end into a dot; horizontal strokes fine, those of $\epsilon$, $\omicron$, and $\Theta$ being either in the middle or high in the letter; the base of $\Delta$ and the cross-stroke of $\Pi$ also fine, and, as a rule, kept within the limits of the letters and not projecting beyond. Here also may be noticed the occurrence in the Codex Alexandrinus of Coptic forms of letters (e.g. $\Delta$, $\omicron$, $\alpha$, and $\nu$) in the titles of books, &c., confirmatory of the tradition of the Egyptian origin of the MS.

![Fig. 12.—The Bible (Cod. Alex.), 5th century.](image-url)

To the 5th century may also belong the palimpsest MS. of the Bible, known from the upper text as the Codex Ephraemi, at Paris (ed. Tischendorf, 1845), and the Octateuch (Codex Sarravallus), whose extant leaves are divided between Paris, Leiden and St Petersburg—both of which MSS. are probably of Egyptian origin. Perhaps of the end of the 5th or beginning of the 6th century is the illustrated Genesis of the Cottonian Library, now unfortunately reduced to fragments by fire, but once the finest example of its kind (Cat. Anc. MSS., i. p. 8). And to about the same time belong the Dio Cassius of the Vatican (Silvestre, pl. 60) and the Pentateuch of the Bibliothèque Nationale (ibid. pl. 61).

In the writing of uncial MSS. of the 6th century there is a marked degeneration. The letters, though still round, are generally of a larger character, more heavily formed, and not so compactly written as in the preceding century. Horizontal strokes (e.g. in $\Delta$, $\omicron$, $\Pi$) are lengthened and finished off with heavy points or finials. The earliest example of this period which has to be noticed is the Dioscorides of Vienna (fig. 13), which is of particular value for the study of the palaeography of early vellum MSS. It is the first uncial example to which an approximate date can be given. There is good evidence to show that it was written early in the 6th century for Juliana Anicia, daughter of Flavius Anicius Olybrius, emperor of the West in 472. Here we already notice the characteristics of uncial writings of the 6th century, to which reference has been made. To this century also belong the palimpsest Homer under a Syriac text in the British Museum (Cat. Anc. MSS., i. pl. 9); its companion volume, used by the same Syrian scribe, in which are fragments of St Luke’s Gospel (ibid., pl. 10); the Dublin palimpsest fragments of St Matthew and Isaiah (T. K. Abbot, Par Palimpsest,Dubl.), written in Egypt; the fragments of the Pauline Epistles from Mount Athos, some of which are at Paris and others at Moscow (Silvestre, pl. 63, 64; Sabas, pl. A), of which, however, the writing has been disfigured by retracing at a later period; the Gospels (Cod. N) written in silver and gold on purple vellum, whose leaves are scattered in London (Cott. MS., Titus C. xv.), Rome, Vienna, St Petersburg, and its native home, Patmos; the fragmentary Eusebian Canons written on gilt vellum and highly ornamented, the sole remains
of some sumptuous volume (Cat. Anc. MSS. i. pl. 11); the Coslin Octateuch (Silvestre, pl. 65); the Genesis of Vienna, and the Codex Rossanensis, and the recently recovered Codex Sinopensis of the Gospels, instances of the very few early illustrated MSS. which have survived. Of the same period is the Codex Marchalianus of the Prophets, which, written in Egypt, follows in its style the Coptic form of uncial.

Reference may here be made to certain early bilingual Graeco-Latin uncial MSS., written in the 6th and 7th centuries. This edition of a sumptuous volume (Cat. anc. MSS. i. pl. 11); the Coslin Octateuch (Silvestre, pl. 65); the Genesis of Vienna, and the Codex Rossanensis, and the recently recovered Codex Sinopensis of the Gospels, instances of the very few early illustrated MSS. which have survived. Of the same period is the Codex Marchalianus of the Prophets, which, written in Egypt, follows in its style the Coptic form of uncial.

Reference may here be made to certain early bilingual Graeco-Latin uncial MSS., written in the 6th and 7th centuries, which, however, have rather to be studied apart, or in connexion with Latin palaeography; for the Greek letters of these MSS. run more or less upon the lines of the Latin forms. The best known of these examples are the Codex-Bezae of the New Testament, at Cambridge (Pal. Soc. pl. 14, 15), and the Codex Claromontanus of the Pauline Epistles, at Paris (Pal. Soc. pl. 63, 64), attributed to the 6th or 7th century; and the Laudian MS. of the Acts of the Apostles (Pal. Soc. pl. 80) of the 7th century. To these may be added the Harleian Glossary (Cat. Anc. MSS. i. pl. 19), also of the 7th century. A later example, of the 8th century, is the Graeco-Latin Psalter, at Paris, MS. Coslin 186 (Omont, Facsimiles d'anc. MSS. of. vii. p. viii.). An offshoot of early Greek uncial writing on vellum is seen in the Meso-Gothic alphabet which Ullas constructed for the use of his countrymen in the 4th century, mainly from the Greek letters. Of the few extant remains of Gothic MSS. the oldest and most perfect is the Codex Argenteus of the Gospels, at Upsala, of the 6th century (Pal. Soc. pl. 118), written in characters which compare with purely written Greek MSS. of the same period. Other Gothic fragments appear in the sloping Uncial hand seen in Greek MSS. of the 7th and following centuries.

About the year 600 Greek uncial writing passes into a new stage. We leave the period of the round and enter on that of the oval character. The letters γ, ς, ι̣, instead of being symmetrically formed on the lines of a circle, are made oval; and other letters are laterally compressed into a narrow shape. In the 7th century also the writing begins to slope to the right, and accents are introduced and afterwards systematically applied. This slanting style of uncials continues in use through the 8th and 9th and into the 10th centuries, becoming heavier as time goes on. In this class of writing there is again the same dearth of dated MSS. as in the round uncial, to serve as standards for the assignment of dates. We have to reach the 9th century before finding a single dated MS., in this kind of writing. It is true that sloping Greek uncial writing is found in a few scattered notes and glosses in Syriac MSS. which bear actual dates in the 9th century, and they are so far useful as showing that this hand was firmly established at that time; but they do not afford sufficient material in quantity to be of really practical use for comparison (see the tables of alphabets in Gardthausen’s Griech. Pallog.). Of more value are a few palimpsest fragments of the Elementa of Euclid and of Gospel Lectionaries which occur also in the Syriac collection in the British Museum, and are written in the 7th and 8th centuries. There is also in the Vatican a MS. (Reg. 886) of the Theodosian code, which can be assigned with fair accuracy to the close of the 7th century (Gardth. Gr. Pal. p. 138), which, however, being calligraphically written, retains some of the earlier rounder forms. This MS. may be taken as an example of transitional style. In the fragment of a mathematical treatise (fig. 14) from Bobbio, forming part of a MS. rewritten in the 8th century and assignable to the previous century, the slanting writing is fully developed. The formation of the letters is good, and conveys the impression that the scribe was writing a hand quite natural to him:

![Fig. 14. —Mathemat. Treatise, 7th century.](image)

It should be noticed that in this MS.—a secular one—there are numerous abbreviations (Wattenbach, Script. gr. specim. tab. 8). An important document of this time is also the fragment of papyrus in the Imperial Library at Vienna, which bears the signatures of bishops and others to the acts of the Council of Constantinople of 680. Some of the signatures are in slanting uncial (Wattenbach, Script. gr. specim., tabb. 12, 13; Gardth., Gr. Pal. tab. 1). Of the 8th century is the collection of hymns (Brit. Mus., Add. MS. 26, 113) written without breathings or accents (Cat. Anc. MSS. i. pl. 14). To the same century belongs the Codex Marcianus, the Venetian MS. of the Old Testament, which is marked with breathings and accents. The plate reproduced from this MS. (Wattenbach, Script. gr. specim., tab. 9) contains in the second column a few lines written in round uncial, but in such a laboured style that nothing could more clearly prove the discontinuance of that form of writing as an ordinary hand. In the middle of the 9th century at length we find a MS. with a date in the Psalter of Bishop Uspensky of the year 862 (Wattenbach, Script. gr. specim., tab. 10). A little later in date is the MS. of Gregory of Nazianzus, written between 868 and 869 (Silvestre, pl. 71); and at the end of the 9th or beginning of the 10th century stands a lectionary in the Harleian collection (Cat. Anc. MSS. i. pl. 17). A valuable series of examples is also given by Omont (Facsimiles des plus anc. MSS. grecs de la Bibl. Nat.). But by this time minuscule writing was well established, and the use of the more inconvenient uncial was henceforth almost entirely confined to church-service books. Owing to this limitation uncial writing now underwent a further calligraphic change. As the 10th century advances the sloping characters by degrees become more upright, and with this resumption of their old position they begin in the next century to cast off the compressed formation and again become rounder. All this is simply the result of calligraphic imitation. Bibles and service-books have always been the MSS. in particular on which finely formed writing has been lavished; and it was but natural that, when a style of writing fell into general disuse, its continuance, where it did continue, should become more and more traditional, and a work of copying rather than of writing. In the 10th century there are a few examples bearing dates. There are facsimiles from three of them, viz. a copy of the Gospels (fig. 15), in the Vatican, of 940 (New Pal. Soc. pl. 103), the Curzez Lectionary of 990, and the Harleian Lectionary of 995 (Pal. Soc. pl. 154, 26, 27). The Bodleian version on the Psalter (D. 4, 1) is likewise of great palaeographic value, being written partly in uncial and partly in minuscules of the middle of the 10th century (Gardth., Gr. Pal. p. 159, tab. 2, col. 4). This late form of uncial writing appears to have lasted to about the middle of the 12th century. (Omont, Facs. p. xxii.). From it was formed the Slavonic writing in use at the present day:
bastic kind of uncial in the west of Europe. This writing
follows, wherever the shapes of the letters permit, the formation
of corresponding Latin characters—the purely Greek forms
being imitated in a clumsy fashion. Such MSS. are the Codex
Augentiensis of Trinity College, Cambridge, of the end of the
9th century (Pal. Soc. pl. 127) and the Psalter of St Nicholas
of Cusa (pl. 128) and the Codex Sangallensis and Boernerianus
of the 10th century (pl. 179). The same imitative characters
are used in quotations of Greek words in Latin MSS. of the
same periods.

Minuscule Writing.—The beautifully formed minuscule book-
hand, which practically superseded the uncial book-hand in
the 9th century, did not spring into existence all at once. Its
formation had been the work of centuries. It was the direct
descendant of the cursive Greek writing of the papyri. It has
been shown above, in tracing the progress of the non-literary,
cursive writing on papyrus, how the original forms of the letters
of the Greek alphabet went through various modifications,
always tending towards the creation of the forms which eventu-
ally settled down into the recognized minuscules or small let-
ters of the middle ages and modern times. The development of these
modifications is apparent from the first; but it was in the Byzant-
tine period especially that the changes became more marked
and more rapid. All the minuscule forms, as we know them in
medieval literature, had been practically evolved by the end of
the 5th century, and in the course of the next two hundred
years those forms became more and more confirmed. In the
large formal cursive writing of the documents of the 6th and
7th centuries we can pick out the minuscule alphabet in the
rough. It only needed to be cast in a calligraphic mould to
become the book-hand minuscule, the later development of
which we have now to trace. This calligraphic mould seems
to have been found in the imperial chancery, whence issu-
ed documents written in a fine round minuscule hand on
an ample scale, as appears from one or two rare surviving ex-
amples attributed to the 8th and 9th centuries (see the facsimile
of an imperial letter, dated variously A.D. 736 or 836, in Watten-
bach, Script. graec. specim. pl. xiv., xvi., and in Omont, Facs.
des plus anc. MSS. graec. pl. xxvi., xxvii., and Brit. Mus. papyri
xxxii.). The fine hand only needed to be reduced in scale
to become the calligraphic minuscule book-hand of the vellum
MSS.

Thus, then, in the 9th century, the minuscule book-hand
came into general use for literature, and, with the finely prepared
vellum of the time ready to receive it, it assumed under the
pens of expert calligraphers the requisite cast, upright, regular
and symmetrical, which renders it in its earliest stages one of
the most beautiful forms of writing ever created.

Greek MSS. written in minuscules have been classed as follow:
(1) codices vetustissimi, of the 9th century and to the middle
of the 10th century; (2) vetusti, from the middle of the 10th
to the middle of the 13th century; (3) recensores, from
the middle of the 13th century to the fall of Constantinople, 1453; (4)
novelli, all after that date.

Of dated minuscule MSS. there is a not inconsiderable number
scattered among the different libraries of Europe. Gardthausen
(Gr. Pal. 344 seq.) gives a list of some thousand, ending at A.D.
1350. But, as might be expected, the major part of these MSS.
belong to the later classes. Of the 9th century there are not ten which
actually bear dates and of these all but one belong to the latter
half of the century. In the 10th century, however, the number
rises to nearly fifty, in the 11th to more than a hundred.

In the period of codices vetustissimi the minuscule hand is
distinguished by its simplicity and purity. The period has been
well described as the classic age of minuscules. The letters are
symmetrically formed; the writing is compact and upright,
or has even a slight tendency to slope to the left. In a word, the
beauty of this class of minuscule writing is unsurpassed. But
in addition to these general characteristics there are special

The breathings also of this class are rectangular, in unison
with the careful and deliberate character of the writing; and
there is but slight, if any, separation of the words. In addition,
as far as has hitherto been observed, the letters run above, or stand
upon, the ruled lines, and do not depend from them as at a later
period. The exact time at which this latter mechanical change
took place cannot be named; like other changes it would naturally
establish itself by usage. But at least in the middle of the
10th century it seems to have been in use. In the Bodleian
MS. of Basil’s homilies of 953 A.D. (Pal. Soc. pl. 82) the new
method is followed; and if we are to accept the date of the 9th
century ascribed to a MS. in the Ambrosian Library at Milan
(Wattenb., Script. gr. specim., tab. 17), in which the ruled
lines run above the writing, the practice was yet earlier. Certain
scirpul peculiarities, however, about the MS. make us hesitate
to place it so early. In the Laurentian Herodotus (W and V,
Exempla, tab. 31), which belongs to the 10th century, sometimes
the one, sometimes the other system is followed in different
parts of the volume; and the same peculiarity happens in the
MS. of Gregory of Nazianzus of A.D. 972 in the British Museum
(Pal. Soc. pl. 25; Exempla, tab. 7). The second half of the 10th
century therefore appears to be a period of transition in this
respect.

The earliest dated example of codices vetustissimi is the copy
of the Gospels belonging to Bishop Uspensky, written in the
year 835. A facsimile is given by Gardthausen (Beiträge) and
repeated in the Exempla (tab. 1). Better specimens have been
photographed from the Oxford MS. of A.D. 888 (Pal. Soc.
65, 66; Exempla, tab. 2) from a MS. of Saints’ Lives at Paris
of A.D. 890 (Omont, Facs. des MSS. gr. datés, pl. 1), and from
the Oxford Plato (fig. 17) of A.D. 895 (Pal. Soc. pl. 81; Exempla,
tab. 3). Sabas (Specim. Palaeograph.) has also given two
facsimiles from MSS. of 880 and 899.

Of dated examples of the first half of the 10th century about a
dozens facsimiles are available.

After the middle of the 10th century we enter on the period of
the codices vetusti, in which the writing becomes gradually
The gradual rounding of the rectangular breathings taken place in this period. In the 11th century the smooth breathing, which would most readily lend itself to this modification, first appears in the new form. In the course of the 12th century both breathings have lost the old square shape; and about the same time contractions become more numerous, having been at first confined to the end of the line.

When the period of codices recentiores commences, the Greek minuscule hand undergoes extensive changes. The contrast between MSS. of the 13th century and those of a hundred years earlier is very marked. In the later examples the hand is generally more sprawling, there is a greater number of exaggerated forms of letters, and marks of contraction and accents are dashed on more freely. There is altogether a sense of greater activity and haste. The increasing demand for books created a larger supply. Greater freedom and more variety appear in the examples of this class, together with an increasing use of ligatures and contractions. The general introduction of paper likewise assisted to break up the formal minuscule hand. To this rougher material a rougher style of writing was suited. Through the 14th and 15th centuries the decline of the set minuscule rapidly advances. The writing becomes even more involved and intricate, marks of contraction and accents are combined with the letters in a single action of the pen, and the general result is the production of a thoroughly cursive hand. In some respects, however, the change was not so rapid. Church books were still ordinarily written on vellum, which, as it became scarcer in the market (owing to the injury done to the trade by the competition of paper), was supplied from ancient codices which lay ready to hand on the shelves of libraries; and in these liturgical MSS. the more formal style of the minuscule was still maintained. In the 14th century there even appears a partial renaissance in the writing of Church MSS., modelled to some extent on the lines of the writing of the 12th century. The resemblance, however, is only superficial; for no writer can entirely disguise the character of the writing of his own time. And lastly there was yet another check upon the absolute disintegration of the minuscule book-hand in the 15th century exercised by the professional scribes who worked in Italy, and who in their calligraphical productions reverted again to the older style. The influence of the Renaissance is evident in many of the MSS. of the Italian Greeks, which served as models for the first Greek printing types.

The Greek minuscule book-hand had, then, by the end of the 15th century, become a cursive hand, from which the modern current hand is directly derived. We last saw the ancient cursive in use in the documents prior to the formation of the set minuscule book-hand, and no doubt it continued in use concurrently with the book-hand. But, as the latter passed through the transformations which have been traced, and gradually assumed a more current style, it may not unreasonably be supposed that it absorbed the cursive hand of the period, and with whatever elements may have survived of the old cursive hand.

LATIN WRITING. I.—THE ROMAN CURSIVE

The course of Latin palaeography runs on the same lines as that of Greek palaeography. In regard to the former, as in regard to the latter, the documents fall into two main divisions: those which are written in the ordinary cursive hand of everyday life, and those which are written in the formal book-hand of literature. But Latin palaeography covers a wider ground than Greek. Greek writing being limited to the expression of the one
writers composed their works. When examining the alphabet of this early Roman cursive hand, we find (as we found in the early Greek cursive) the first beginnings of the minuscule writing of the middle ages. The slurring of the strokes, whereby the bows of the capital letters were lost and their more exact forms

modified, led the way to the gradual development of the small letters. With regard to the particular forms of letters employed in the waxen tablets, compare the tables in Corp. inscr. lat., vols. iii., iv. The letter A is formed by a main stroke supporting an oblique stroke above it and the cross bar is either omitted, or is indicated by a small vertical stroke dropping, as it were, out of the letter.

The main stroke of B dwindles to a slight curve, and the two bows are transformed into a long bent stroke so that the letter takes the shape of a stilted a or of a. The D is chiefly like the uncial ω; the E is generally represented by the old form || in inscriptions and in the Faliscan alphabet. In the modified form of G the first outline of the flat-headed g of later times appears; H, by losing half of its second upright limb in the haste of writing, comes near to being the small h. In the Pompeian tablets M has the four-stroke form ||| as in the graffito; in the Dacian tablets it is a rustic capital, sometimes almost an uncial ω. The hastily written O is formed by two strokes both convex, almost like a. As to the general character of the writing, it is close and compressed, and has an inclination to the left. There is also much combination or linking together of letters (Corp. inscr. lat. iii. tab. A). These peculiarities may, in some measure, be ascribed to the material and to the confined space at the command of the writer. The same character of cursive writing has also been found on a few tiles and potsherds inscribed with alphabets or short sentences—the exercises of children at school (Corp. inscr. lat. iii. 562).

In writing with the pen upon the smooth and unresisting surface of papyrus, the scribe would naturally write a more fluent hand. The disjointed writing of the graffito and the tablets was changed for one which gradually became more consecutive and which naturally tended in course of time to

language of a single people has a comparatively narrow and simple career. On the other hand, the Latin alphabet, having been adopted by the nations of western Europe, underwent many transformations in the course of development of the national handwritings of the different peoples, and consequently had a wide and varied career. But in one respect Latin palaeography is at a disadvantage as compared with the sister branch. As we have seen, Greek documents are extant dating back to the 4th century B.C., and the development of Greek writing can be fairly well illustrated by a series of examples of the succeeding centuries. There is no such series of Latin documents available to afford us the means of tracing the growth of Latin writing to the same remote period. No Latin document, either of a literary or of a non-literary character, has yet been recovered which can be placed with certainty earlier than the Christian era. Egypt, while giving up hundreds and thousands of documents in Greek, has hitherto yielded but little in Latin, even of the 1st century, and little too of the next following centuries. Indeed, for our knowledge of Latin writing of the 1st century we still have to depend chiefly upon the results of excavations at Pompeii and Herculaneum and in the Roman catacombs, upon the wall-scribblings which have been laid bare, and upon the waxen tablets and the few papyri which have thence been recovered.

At the time when we come into touch with the first extant examples of Roman writing, we find a few instances of a literary or book-hand as well as a fairly extensive variety of cursive hands. It will be convenient in the first place to examine the Roman cursive writing during the early centuries of our era. Then, for the moment suspending further research in this branch of our subject, we shall proceed to describe the literary script and to trace the development of the large form of book-hand, or majuscule writing, in its two divisions of capitals and uncials, and of the intermediate styles composed of a mixture of large and small letters, or consisting of a blend of the two classes of letters which has received the name of half-uncial. Then we shall turn to the formation of the minuscule writing of the middle ages.

The materials for the study of the early Roman cursive hand have been found in the wall-scribblings, or graffiti, of Pompeii and Herculaneum and Rome (collected in the Corp. inscr. lat., vol. iv.); in the series of 137 libelli or waxen tablets, consisting of prescriptions and other deeds connected with sales by auction and tax receipts discovered in the house of the banker L. Caecilius Jucundus at Pompeii, and bearing dates of A.D. 15, 27, and 53–62 (published in C.I.L. iv., supplement); in a few scattered papyri from Egypt; and in a set of four-and-twenty waxen tablets bearing dates ranging from A.D. 131 to 167, which were found in fragmentary mining works in the neighbourhood of Alburnus Major (the modern Verespatak) in Dacia (C. I. L. iii.).

It will have been observed that in the case of the above documents there are three different kinds of material on which they have been inscribed: the plaster surface of walls, the waxen coatings of tablets, and the smooth surface of papyri. The two former may be classed together as being of a nature which would offer a certain resistance to the free movement of the stylus; while in the case of papyrus the writing-rod or pen would run without impediment. Hence, in writing on the former materials there was a natural tendency to form the letters in disconnected strokes, to make them upright or even inclined to the left, and to employ vertical strokes in preference. The three following specimens from the graffiti and the two sets of tablets will demonstrate the conservative character of this kind of writing, covering as they do about a century and a half. This conservativeness may suggest the probability that the hand seen in the graffiti and the Pompeian tablets had not changed very materially from that practised a century or more earlier, and that it is practically the hand in which the Roman classical
slopes to the right in the effort to be more current and to write letters in connexion without lifting the pen. One of the earliest available examples of Latin writing on papyrus to which an approximate date can be assigned is a fragment at Berlin containing portions of speeches delivered in the senate, said to be of the reign of Claudius, A.D. 41–54 (Steffens, Lat. Pal. taf. 101). The writing, though still somewhat restrained and admitting but little linking of the letters, is yet of a more flowing character than that of the contemporary tablets and graffiti.

We have to pass into the second century before finding the most perfect Latin document on papyrus as yet discovered (fig. 23). This is now in the British Museum, and records the purchase of a slave-boy by an officer in the Roman fleet of Misenum stationed on the Syrian coast, A.D. 166 (Pal. Soc. i. 190; Archaeologia liv. p. 433). The writing of the body of the document is in a formal cursive, generally of the same formation as the inscriptions on the Dacian waxen tablets of the 2nd century, as will be seen from the accompanying facsimile of a few lines (fig. 23).

With this example of legal handwriting of the 2nd century it is interesting to compare two specimens of more ordinary cursive in different styles found in private letters of about the same time. The first (fig. 24) is taken from a fragmentary letter of the year 167 (Grenfell and Hunt, Greek Papyri, 2nd series, cviii.) and is a typical example of a hurried style.

The second (fig. 25) is from a letter written by one Aurelius Archelaus to Julius Domitius, triunviris militum, recommending a friend named Theon, of the 2nd century (Oxyrhynchus Papyri, i., xxxii.), an instance apparently of slow and imperfect penmanship, every letter painfully and separately formed, yet not in the detached strokes characteristic of the writing of the graffiti and the tablets.

In the examples above we recognize practically the same alphabet as in the graffiti and tablets, but with certain exceptions, particularly in the shape of the letter E, which is either normal or written very cursorily as an acute-angled tick, and in the reversion of other letters to the more normal capital forms.

There is not sufficient material to trace step by step the development of the Roman cursive hand between the 2nd and the 5th centuries; but still, with the few scattered examples at hand, there seems to be reason for conjecture that Latin writing on papyrus passed through phases not very dissimilar to those of Greek writing on the same material. For, when we emerge from the 3rd century, we find an enlarged flowing hand, as in the Latin translation of the fables of Babrius in a fragmentary papyrus of the Amherst collection (No. xxvi.), ascribed to the 3rd or 4th century, and in a letter of recommendation from an Egyptian official of the 4th century, now at Strassburg (Archiv. für Papyrforschung, iii. 2. 168); the handwriting of the latter recalling the large style of the Greek cursive of the Byzantine period (fig. 26). That there should be an affinity between the writing of Greek and that of Latin papyri emanating from Egypt is naturally to be expected.

**Fig. 25.—Letter, 2nd century.**

Jam tibi et pristine commen daueram Theonem amicum meum et modolo quoque puto domine ut tuum ant oculos habeas tandem mi est e nim tales omo ut anretur a te)

(Cum in omnibus bonis benig[nitas]—
etiam scholasticos et maxime qui—
[onom]nia centa tuae traduntur quod—

This example shows what an immense advance had by this time been made in the formation of the minuscule hand, and but little more is required for its completion. It is to be noted, however, that the peculiar old form of letter B with the loop on the left still persists. But only a short time was now needed to bring this letter also in a new shape into line with the other members of the growing minuscule alphabet.

At this point must be noticed a very interesting and important class of the Roman cursive hand which stands apart from the general line of development. This is the official hand of the Roman Chancery, which is unfortunately represented by only two fragmentary papyri of the 5th century (fig. 27), and proves to be a curious moulding of the cursive in a calligraphic style, in which, however, the same characters appear as in other Roman cursive documents, if somewhat disguised. The papyri contain portions of two rescripts addressed to Egyptian officials, and are said to have been found at Philae and Elephantine. Both documents are in the same hand; and the fragments are divided between the libraries of Paris and Leiden. For a time the writing remained undeciphered, and Champollion-Figeac, while publishing a facsimile (Charles et M.S.S. sur papyrus, 1840, pl. 14), had to confess that he was unable to read it. Massmann, however, with the experience gained in his work upon the waxed tablets, succeeded without much difficulty in reading the fragment at Leiden (Libellus aurarius, p. 147), and was
followed by M. de Wailly, who published the whole of the fragments (*Mem. de l’Institut* (1842), xv. 399). Later, Mommsen and Jaffé have dealt with the text of the documents (*Jahrbuch des. germ. deut. Rechts* (1863), vi. 398), and compared in a table the forms of the letters with those of the Dacian tablets.

![Fig. 27.—Deed of the Imperial Chancery, 5th century. (portionem ipsi debitaem resarcire nec unum precatorem ex instrumento)](image)

The characters are large, the line of writing being about three-fourths of an inch deep, and the heads and tails of the long letters are flourished; but the even slope of the strokes imparts to the writing a certain uniform and graceful appearance. As to the actual shape of the letters, as will be seen from the reduced facsimile here given, there may be recognized in them only a current form of those which have been described above. The A and R may be distinguished by noticing the different angle at which the strokes are applied; the B, to suit the requirements of the more current style, is no longer the closed d-shaped letter of the tablets, but is open at the bow and more nearly resembles a reversed b; the tall letters f, h, i, and long s have developed loops; O and e-shaped U are very small, and written high in the line. The letters which seem to differ essentially from those of the tablets are E, M, N. The first of these is probably explained correctly by Jaffé as a development of the earlier || quickly written and looped, and may be compared with the tick-shaped letter noticed above. The M and N have been compared with the minuscule forms of the Greek μ and ν, as though the latter had been adopted; but they may with better reason be explained as merely cursive forms of the Latin capitals M and N. That this hand should have retained so much of the older formation of the Roman cursive is no doubt to be attributed to the fact of its being an official style of writing which would conform to tradition.

To continue the development which we saw attained in the letter of the 4th century above (fig. 26) we turn to the documents on papyrus from Ravenna, Naples, and other places in Italy, which date from the 5th century and are written in a looser and more straggling hand (fig. 28). Examples of this hand will be found in largest numbers in Marin’s work specially treating of these documents (*I papiiri diplomatici*), and also in the publications of Mabillon (*De re diplomatica*), Champollion-Figeac (*Chars et MSS. sur papyrus*), Massmann (*Urkunden in Neapel und Aresso*), Gloria (*Palaeogra.,*), as well as in *Facts of Ancient Charters in the British Museum*, pt. iv., 1878, Nos. 45, 46, and in the *Facsimiles of the Palaeographical Society*.

![Fig. 28.—Deed of Sale (Ravenna), A.D. 572. (huius splendensissimae urbis)](image)

The letter a has now lost all trace of the capital; it is the open u-shaped minuscule, developed from the looped uncial (ⅉ, χ); the b, throwing off the loop or curve on the left which gave it the appearance of a, has at length developed one on the right, and appears in the form familiar in modern writing; minuscule m, n, and o are fully formed (the last never joining a following letter, and thus always distinguishable from α); p, q, and r approach to the long minuscules, and s, having acquired an incipient tag, has taken the form γ which it keeps long after.

This form of writing was widely used, and was not confined to legal documents. It is found in grammatical works, as in the second hand of the palimpsest MS. of Licinius (Cat. Anc. MSS., pt. ii., plis. 1, 2) of the 6th century, and in such volumes as the Josephus of the Ambrosian Library of the 7th century (*Pal. Soc. pl. 59*), and in the St Avitus of the 6th century and other MSS. written in France. It is indeed only natural to suppose that this, the most convenient, because cursive, hand, should have been employed for ordinary writing MSS. which were in daily use. That so few of such MSS. should have survived is no doubt owing to the destruction of the greater number by the wear and tear to which they were subjected.

**Latin Writing II.—Literary Hands**

We have now to return to the 1st century, the date from which we started in the investigation of the Roman cursive writing, and take up the thread of the history of the book-hand of literature, a few rare examples of which have survived from the ruins of Herculaneum. That a Roman book-hand existed at a still earlier period is quite certain. The analogy of the survival of very ancient examples of a Greek literary hand is a sufficient proof; and it is a mere truism to say that as soon as there was a literature, there was likewise a book-hand for its vehicle. No work could be submitted for sale in the market that was not written in a style legible to all. Neatly written copies were essential, and the creation of a formal kind of script formed for the purpose naturally resulted. Such formal script must, however, be always more or less artificial as compared with the natural current hand of the time, and there must always be an antagonism between the two styles of script; and, as we have seen in Greek palaeography, the book-hand is always subject to the invading influence of the natural hand.

**Capital Writing**—Among the Herculaneum fragmentary papyri, then, we find our earliest examples of the Roman literary hand, which must be earlier than a.d. 79, the year of the destruction of the city; and those examples prove to us that the usual literary hand was written in capital letters. Of these letters there are two kinds—the square and the rustic. Square capitals may be defined as those which have their horizontal lines at right angles with the vertical strokes; rustic letters are not less accurately formed, nor, as their title would seem to imply, are they rough in character, but, being without the exact finish of the square letters, and being more readily written, they have the appearance of greater simplicity. In capital writing the letters are not all of equal height; F and L, and in the rustic sometimes others, as B and R, overlap the rest. In the rustic style the forms of the letters are generally lighter and better proportioned, with short horizontal strokes more or less oblique and wavy. Both styles of capital writing were obviously borrowed from the lapidary alphabets employed under the empire. Both styles were used for public notices inscribed on the walls of Pompeii and other places. But it has been observed that scribes with a natural conservatism would perpetuate a style some time longer in books than it might be used in inscriptions. We should therefore be prepared to allow for this in ascribing a date to a capital written MS., which might resemble an inscription older by a century or more. Rustic capitals, on account of their more convenient shape, came into more general use; and the greater number of the early MSS. in capitals which have survived are consequently found to be in this character. In the *Exempla colitum latinorum* of Zangemeister and Wattenbach are collected specimens of capital writing.

The literary fragments of papyrus from Herculaneum are written generally in rustic capitals, either of the firm, solid character used in inscriptions, or of the lighter style employed in the fragments of a poem on the battle of Actium (*fig. 29*). As this poem is the earliest literary work and of any extent which has been recorded in the book-hand, a specimen of the writing is here given. Its period must necessarily lie between the year 31 b.c. the date of the battle and A.D. 79; and therefore we may place it at least early in the 1st century.

That the rustic capital hand was generally adopted for finely written literary MSS. from the period of our earliest examples onwards through the centuries immediately following may be
assumed from the fact of that character being found so widely in
favour when we come down to the period of the vellum MSS.
Unfortunately no examples have survived to fill the gap between
the first century and the oldest of the vellum codices written in
rustic capitals of the 4th century. Of the three great MSS.
of Virgil preserved in the Vatican Library, which are written in

this character, the first in date is that known as the Schedae
Vaticanae (Exempla, tab. 13; Pal. Soc. pl. 116, 117), a MS.
famous for its series of well-finished illustrative paintings in
classical style; it is ascribed to the 4th century. The other two
MSS. are known as the Codex Palatinus (Exempla, tab. 14, 15; Pal. Soc. pl. 117-119), and are now
generally assigned to the 5th century. All three MSS. no doubt
must always have been regarded as choice works; and the large
scale of the writing employed, particularly in the case of the
Romanus and the Palatinus, and the consequently magnificent
size of the MSS. when complete, must indicate an unusual
importance attaching to them. They were \textit{éditions de luxe}
of the great Roman poet. The writing of the Codex Palatinus
(Fig. 30) especially is most exact, and is manifestly modelled
on the best type of the rustic hand as seen in the inscriptions.

\[

\]

Fig. 30.—Virgil (Cod. Palatinus) 5th century.

(Testaturque deos iterum se ad proelia cogi
Bis iam Italos hostis haec altera foedera)

In assigning dates to the earliest MSS. of capital-writing, one
feels the greatest hesitation, none of them bearing any internal
evidence to assist the process. It is not indeed until the close
of the 5th century that we reach firm ground—the Medicean
Virgil of Florence having in it sufficient proof of having been
written before the year 494. The writing is in deliberately-
formed letters, rather more spaced out than in the earlier examples
(Exempla, tab. 10; Pal. Soc. pl. 86). Another ancient MS. in rustic capitals is the Codex Bemmarius of Terence of the
4th or 5th century (Exempla, tab. 8, 9; Pal. Soc., pl. 135), a volume which is also of particular interest on account of its
marginal annotations, written in an early form of small hand.
Among palimpsests the most notable is that of the Cicero \textit{In terentium} of the Vatican (Exempla, tab. 4).

Of vellum MSS. in square capitals the examples are not so
early as those in the rustic character. Portions of a MS. of
Virgil in the square letter are preserved in the Vatican, and other
leaves of the same are at Berlin (Exempla, tab. 14). Each page,
however, begins with a large coloured initial, a style of ornamentation
which is never found in the very earliest MSS. The date
assigned to this MS. is therefore the end of the 4th century.
In very similar writing, but not quite so exact, are some fragments
of another MS. of Virgil in the library of St Gall, probably of
a rather later time (Exempla, tab. 14a; Pal. Soc., pl. 208).

In the 6th century capital-writing enters on its period of
decadence, and the examples of it become imitative. Of this
period is the Paris Prudentius (Exempla, tab. 15; Pal. Soc. pl.
20, 30) in rustic letters modelled on the old pattern of early
ingscriptions, but with a very different result from that obtained
by the early scribes. A comparison of this volume with such
MSS. as the Codex Romanus and the Codex Palatinus shows the
later date of the Prudentius in its widespread writing and in
certain inconsistencies in forms. Of the 7th century is the
Turin Sedulius (Exempla, tab. 16), a MS. in which uncial writing
also appears—the rough and mishapen letters being evidences
of the cessation of capital writing as a hand in common use.
The latest imitative example of an entire MS. in rustic capitals
is in the Utrecht Psalter, written in triple columns and copied,
to all appearance, from an ancient example, and illustrated with
pen drawings. This MS. may be assigned to the beginning of
the 8th century. If there were no other internal evidence of late
date in the MS. the mixture of uncial letters with the
capitals would decide it. In the Psalter of St Augustine's
Canterbury, in the Cottonian Library (Pal. Soc. pl. 19; Cat.
Anc. M.S. ii. pls. 12, 13), some leaves at the beginning are
written in this imitative style early in the 8th century; and again
it is found in the Benedictional of Bishop Aethelwold (Pal. Soc.
pl. 143) of the 10th century. In the sumptuous MSS. of the
Carlovingian school it was continually used; and it survived for
such purposes as titles and colophons for some centuries, usually
in a degenerate form. As an instance of a book from this last
period is the \textit{Urcial Writing}.—There was also another majuscule form of writing, besides capitals, employed as a literary book-hand
at an early date, but not coeval with the early period of capital
writing. This second book-hand was the so-called Uncial hand,
believing the capital form of writing, in which the square angles of the original letters were rounded off and certain new
curved shapes were introduced, the characteristic letters of
the uncial alphabet being $A, B, C, D, E$. The origin of some
of these rounded letters may be traced in certain forms of the
Roman cursive letters of the graffiti and the tablets. But a
considerable length of time elapsed before the fully developed
unical alphabet was evolved from these incipit forms. In fact
it is only in the vellum MSS. that we first find the firmly written
literary uncial hand in perfect form. No doubt the new material,
vellum, with its smooth hard surface, immediately afforded the
means for the calligraphic perfection with which we find the
unical writing inscribed in these codices.

From the occurrence of isolated uncial forms in inscriptions,
the general period of growth of this uncial literary hand has
been determined to lie between the later part of the 3rd century
and the 4th century. Uncial letters are especially plentiful in
Roman-African inscriptions of the 3rd century; but certain
letters of the uncial alphabet are not as yet therein matured;
minuscule forms of a few letters, particularly $b$ and $d$, are employed.
The discovery also, at Oxyrhynchus, of a fragmentary papyrus
of the 3rd century, containing a portion of an epitome of Livy,
presents us with an example of the uncial hand in progress of
formation for literary purposes, the text being composed mainly
of letters of the uncial type, but including a certain proportion
of letters, as $b, d, m, r$, of the minuscule or small character.
At length in the 4th century, as already stated, the perfected
uncia literary alphabet is found in the vellum codices.

There are still extant a very large number of Latin uncial
MSS., a proof of the wide use of this form of literary writing in
the early middle ages.

The \textit{Exempla} of Zangemeister and Wattenbach, so often
cited above, contains a series of facsimiles which illustrate
its progress through its career. The letter $€$ also has been adopted
by the editors as a test letter, in the earlier form of which
the last limb is not curved or turned in. The letter $€$ also, in its
earlier and purer form has the cross stroke placed high. But
as in every style of writing, when once developed, the earliest examples
are the best, being written with a free hand and natural
stroke. The Gospels of Vercelli (Exempla, tab. 20), said to have
been written by the hand of Eusebius himself, and which may
indeed be of his time, is one of the most ancient uncial MSS.
Its narrow columns and pure forms of letters have the stamp of
antiquity. To the 4th century also is assigned the palimpsest
Ciceron \textit{De republica} in the Vatican (Exempla, tab. 17; Pal. Soc.
pl. 160), a MS. written in fine large characters of the best type; and a very ancient fragment of a commentary on an ante-Hieronymian text, in three columns, has also survived at Fulda (Exempla, tab. 21). Among the uncial MSS. of the 5th century of which good photographic facsimiles are available are the two famous codices of Livy, at Vienna (fig. 31) and Paris (Exempla, tab. 15, 19; Pal. Soc. pl. 31, 32, 183).

![Image](Exempla, tab. 52; Pal. Soc. pl. 31, 32, 183)

**Fig. 31.—Livy (Vienna MS.), 5th century.**

To distinguish between uncials of the 5th and 6th centuries is not very easy, for the character of the writing changes but little, and is free from sign of weakness or wavering. It may, however, be noticed that in MSS. which are assigned to the latter century there is rather less compactness, and occasionally, as the century advances, there is a slight tendency to artificiality.

When the 7th century is reached there is every evidence that uncial writing has entered on a new stage. The letters are more roughly and carelessly formed, and the compactness of the earlier style is altogether wanting. From this time down to the age of Charlemagne there is a continual deterioration, the writing of the 8th century being altogether misshapen. A more exact but impartitious hand was, however, at the same time employed, when occasion required, for the production of calligraphic MSS., such as Biblical and liturgical books. Under the encouragement given by Charlemagne to such works, splendid uncials were written in ornamental style, often in gold, several of which have survived to this day.

**Mixed and Half-uncial Writing**—It is obvious that the majuscule styles of literary writing, viz. the square capital, the rustic capital and the uncial, were of too elaborate and too stately a character to serve all the many requirements of literature. The capital hands, as we have seen, appear to have been employed, at least in many instances, for codices produced on a grand scale, and presumably for special occasions; and if the uncial hand had a longer and wider career, yet in this case also there must often have been a sense that the employment of this fine character gave a special importance and value to the MS. It is not improbable that the survival of so large a number of uncial MSS. is due to the special care that they received at the hands of their owners. Other more manageable styles of writing were necessary, and concurrently with the majuscule hands other forms were developing. The hand which bears the name of Half-uncial was finally evolved, and had itself an important career as a book-hand as well as exercising a large influence on the medieval minuscule hand of literature.

From the first, as we have seen in the case of the graffito and the tablets, a mingling of capital forms and minuscule forms was prevalent in the non-literary style of writing. There are indications that the same mingling of the two streams was allowed in writing of a literary character. It appears in a rudimentary state in a papyrus fragment from Herculanum (Exempla, tab. 2 b); and it appears in the epistle of Livy of the 3rd century found at Oxyrhynchus, in which minuscule letters are interspersed among the uncial text. From the regularity and ease with which this MS. is written, it is to be assumed that the mixed hand was ordinarily practised at that time. It is often employed for marginal notes in the early vellum codices. It is used for the text of the Verona Gaius (Exempla, tab. 24) of the 4th century, in which, besides the ordinary uncial shapes, 𐊡 is also found as a minuscule, r as the transitional r, and s as the tall letter v. Again, in the uncial Florentine Pandects of the 6th century appears a hand which contains a large admixture of minuscule forms (Exempla, tab. 34). From these and other instances it is seen that in uncial MSS. of a secular nature, as in works relating to law and grammar, the scribe did not feel himself restricted to a uniform use of the larger letters, as he would be in producing a church book or calligraphic MS.

But the mixed hand, although partaking something of the nature of the Half-uncial hand, was not actually that form of writing. The Half-uncial hand was not only a mingling of uncial and minuscule forms, but also a blending of them, the uncial element yielding more or less to the minuscule influence, while the minuscule element was reacted upon by the uncial sentiment of roundness and sweeping curves. In its full development the Half-uncial, or Roman Half-uncial as it is also called, was not for a few lingering pure uncial forms, might equally well be described as a large-type minuscule hand. It has, in fact, sometimes resembled the pre-Carolingian minuscule. An early form of this writing is found in the papyrus fragment of Sallust’s Catiline, perhaps of the early 5th century, recently recovered at Oxyrhynchus. In vellum codices of the 5th, 6th and 7th centuries Half-uncial writing of a very fine type is not uncommon. It is used for the marginal scholia of the Bembine Terence, of the 7th century. The MS. of the Fasti consulares, at Verona, brought down to 494 A.D. (Exempla, tab. 30), is also in this hand. But the earliest MS. of this class to which a more approximate date can be given is the Hilary of St Peter’s at Rome (fig. 32), which was written in or before the year 509 or 510 (Exempla, tab. 52; Pal. Soc. pl. 136); the next is the Sulpicius Severus of Verona, of 517 (Exempla, tab. 32); and of the year 569 a beautifully written MS. at Monte Cassino containing a Biblical commentary (Exempla, tab. 3).

**Fig. 32.—St Hilary, A.D. 500-510.**

(episcopi manum innocent[ae]m)—

[lin guam non ad falsi[quium coeg[isti]]—

nationem anterioris sentent[iae]—)

Other examples, of which good facsimiles may be consulted, are the Corbél MS. of Canons, at Paris (Exempla, tab. 41, 42), the St Severianus at Milan (Pal. Soc. pl. 161, 162), the Ashburnham St Augustine (Pal. Soc. ii. 9), and the Paris St Augustine (New. Pal. Soc. pl. 80), of the 6th century; and the Cologne MS. of Canons (Exempla, tab. 44), and the Josephus (Pal. Soc. pl. 136) and St Ambrose (Pal. Soc. pl. 137) of Milan, of the 6th and 7th centuries.

The influence which the Half-uncial literary hand exercised upon the minuscule book-writing of the 7th and 8th centuries may be traced in greater or less degree in the continental MSS. of that period. We shall find that it formed the basis for the beautiful national handwritings of Ireland and Britain; and it played an important part in the Carolingian reform of the book-hand of the Frankish Empire.

**Latin Writing. III.—The National Hands.**

We have now to follow the rise and development of the national handwritings of western Europe, all of which were derived from the Roman hand, but from different phases of it. While the Roman Empire was the central power controlling its colonies and conquests, the Roman handwriting, however far apart might be the several countries in which it was current, remained practically one and the same. But, when the empire was broken up and when independent nationalities arose upon its ruins and advanced upon independent paths of civilization, the handwriting inherited from Rome gradually assumed distinctive characters and took the complexes of the several countries, unless from some accident the continuity of the effects of the Roman occupation was disturbed, as it was in Britain by the Saxon invasion. On the continent of western Europe, in Italy, in Spain, in Gaul, the Roman cursive hand had become the common form of writing, and it remained the framework on which the national hands of those countries developed. Thus
grew the Lombardic hand of Italy, the Visigothic hand of Spain, and the Merovingian and, later, the Carolingian hand of the Frankish Empire. The earliest charters of the three national divisions, written in cursive hands directly descending from the Roman cursive, and dating generally from the 7th century, still remained related in their general style. It was in the book-hands, elaborated from the cursive character, that the lines of national demarcation became more clearly defined, although naturally there occur also many examples in mixed styles which it is difficult to assign to one or another country.

**Lombardic Writing.**—The national handwriting of Italy did not follow one and the same lines of development throughout the peninsula. In ordinary documents the cursive hand which is seen in the Ravenna deeds, the direct descendant of the Roman cursive, continued in use, growing, in course of time, more and more intricate and difficult to read, the earliest examples, down to the middle of the 9th century, being in the large straggling character of their prototype. The illegible scrawl into which the hand finally degenerated in notarial instruments of southern Italy was at length suppressed by order of Frederick II. (A.D. 1212–1250). But at an early date the Lombardic book-hand was being formed out of this material. In northern Italy new influences were brought into action by Charlemagne's conquest, the independent growth of the native hand was superseded, and a mixed style in which the Merovingian type was interwoven with the Italian was produced, to which the name of Franco-Lombardic has been given (see below, fig. 39). But in the Lombardic duchies of the south the native Lombardic book-hand had an unimpeded growth. In such centres as the monasteries of Monte Cassino near Naples and La Cava near Salerno, it took in the 9th century a very exact and uniform shape. From this date the attention which it received as a calligraphic form of writing, accompanied with accessory ornamentation of initial letters, brought it to a high state of perfection in the 11th century, when by the peculiar treatment of the letters, they assume that strong contrast of light and heavy strokes which when exaggerated, as it finally became, received the name of broken Lombardic. This style of hand lasted to the 12th century.

**Papal Documents.**—A word must be said in this place regarding the independent development of the hands used in the papal chancery, that great centre which had so wide an influence by setting the pattern for the handsome round-hand writing which became so characteristic of the Italian script. Specimens of a special style of writing, founded on the Lombardic and called *littera romana* (fig. 34) are to be seen in the early papal documents on papyrus dating from the latter part of the 8th century. In the earliest examples it appears on a large scale, and has rounded forms and sweeping strokes of a very bold character. Derived from the official Roman hand, it has certain letters peculiar to itself, such as the letter *a* made almost like a Greek *a* in the form of a loop, and some as a circle with a knot at the top. This hand may be followed in examples from A.D. 788 through the 9th century (Facs. de chartes et diplomes, 1866; Ch. Figeac, *Chartes et doc. sur papyrus*, i–xii.; Letronne, *Diplom. meros. atal.*, pl. 48. In a bull of Silvester II., dated in 999 (Bibl. l'Ecs. des chartes, vol. xxxvii.), we find the hand becoming less round; and at the end of the next century, under Urban II., in 1107 (Mabillon, *De re dipl. suppl. p. 115*) and 1098 (Sickel, *Mon. graph. v.*), it is in a curious angular style, which, however, then disappears. During the 11th and 12th centuries the imperial chancery hand was also used for papal documents, and was in turn displaced by the exact and calligraphic papal Italian hand of the later middle ages.

**Visigothic Writing.**—The Visigothic writing of Spain ran a course of development not unlike that of the Lombardic. In the cursive hand attributed to the 7th century the Roman cursive has undergone little change in form; but another century developed a most distinctive character. In the 8th century appears the set book-hand in an even and not difficult character, marked by breadth of style and a good firm stroke. This style is maintained through the 9th century with little change, except that there is a growing tendency to calligraphy. In the 10th century the writing deteriorates; the letters are not so uniform, and, when calligraphically written, are generally thinner in stroke. The same changes which are discernible in all the handwriting of western Europe in the 11th century are also to be traced in the Visigothic hand—particularly as regards the rather rigid character which it assumes. It continued in use down to the beginning of the 12th century. Perhaps the most characteristic letter of the book-hand is the *q*-shaped *g*. The following specimens (figs. 35, 36) illustrate the Visigothic as written in a large heavy hand of the 9th century (Cat. Anc. MSS. ii. Plate 37), and in a calligraphic example of 1109 (Pal. Soc. Plate 48).
PALAEOGRAPHY

574

[ENGLISH HANDS]

century, the character is large and at first not so intricate as it becomes later in this period. The writing then grows into a more regular form, and in the 7th century a small hand is established, which, however, still retains the exaggerated heads and tails of letters. The direct course of this chancery hand may then be followed in the imperial documents, which from the second half of the 9th century are written in a hand more set and evidently influenced by the Carolingian minuscule. This form of writing, still accompanied by the lengthened strokes already referred to, continued in force, subject, however, to the varying changes which affected it in common with other hands, into the 12th century. Its influence was felt as well in France as in Germany and Italy; and certainly of its characteristics also appear in the court-hand which the Normans brought with them into England.

The book-hand immediately derived from the early Merovingian diplomatic hand is seen in MSS. of the 7th and 8th centuries in a very neatly written but not very easy hand (Cat. Anc. MSS. ii. Plates 29, 30; Arndt, Schrifftas. 28).

---

But other varieties of the literary hand as written in France are seen to be more closely allied to the Roman cursive. The earliest example is found in the papirus fragments of writings of St. Avitus and St. Augustine of the 6th century (Études paléogr. sur des papyrus du Vème siècle, Geneva, 1866); and other later MSS. by their diversity of writing show a development independent of the cursive hand of the Merovingian charters. It is among these MSS. that those examples already referred to occur which more nearly resemble the Lombardic type.

It is among these MSS. that those examples already referred to occur which more nearly resemble the Lombardic type.

---

The uncial and half-uncial hands had also their influence in the evolution of these Merovingian book-hands; and the mixture of so many different forms accounts for the variety to be found in the examples of the 7th and 8th centuries. In the Notice sur un MS. Mérovingien d’Eugyppus (1875) and the Notice sur un MS. Mérovingien de la Bibl. d’Épinal (1878), Delisle has given many valuable facsimiles in illustration of the different hands in these two MSS. of the early part of the 8th century. See also Exempl. Cod. Lat. (pab. 57), and autographs in Cat. Anc. MSS. ii. There was, however, through all this period a general progress towards a settled minuscule writing which only required a master-hand to fix it in a purified and calligraphic form. How this was effected will be described below, after disposing of the early national writing of our own islands.

Irish Writing.—The early history of the palaeography of the British Isles stands apart from that of the continental schools. As was noticed above, the Roman handwriting which was used by the Roman settlers in Britain and was imparted to them by the native Britons was swept out of existence when the Saxon invasion abruptly destroyed the continuity of Roman civilization in these islands. Britain had to wait a long time for the reappearance of Roman writing in the country; but it was destined to reappear, though in a different phase, in book-form, not in cursive form; and not directly, but through another channel. That channel was Ireland.

It is evident that the civilization and learning which accompanied the establishment of an ancient Church in Ireland could not exist without a written literature. The Roman missionaries brought with them certain calligraphic models, and copied the Gospels and other books, and it cannot be doubted that through intercourse with England the Irish would obtain continental MSS. in sufficient numbers to serve as models for their scribes. From geographical and political conditions, however, no continuous intimacy with foreign countries was possible; and we are consequently prepared to find a form of writing borrowed in the first instance from a foreign school, but developed under an independent national system. In Ireland we have an instance how conservative writing may become, and how it will hand on old forms of letters from one generation to another when there is no exterior influence to act upon it. After once obtaining its models, the Irish school of writing was left to work out its own ideas, and continued to follow one direct line for centuries. The subsequent English conquest had no effect upon the national handwriting. Both peoples in the island pursued their own course. In MSS. in the Irish language the Irish character of writing was naturally employed; and the liturgical books produced in Irish monasteries by Irish monks were written in the same way. The grants and other deeds of the English bishops which were drawn up by the monks who were their scribes in their then national writing. The Irish handwriting went on in its own unbroken course, and its consequent unchanging form makes it so difficult a matter to assign accurate dates to Irish MSS.

The early Irish handwriting is of two classes—the round and the pointed. The round hand is found in the earliest examples; the pointed hand, which also was developed at an early period became the general hand of the country, and survives in the native writing of the present day. Of the earliest surviving MSS. written in Ireland none are found to be in pure uncial letters. That uncial MSS. were introduced into the country by the early missionaries may be due to the fact that that character was so commonly employed as a bookhand, and especially for sacred texts. Nor is it possible that Irish scribes may have practised this hand. The copy of the Gospels in unials, found in the tomb of St. Kilian, and preserved at Würzburg, has been quoted as an instance of Irish unialis. The writing, however, is the ordinary unialis, and bears no marks of the Irish style. The Irish pointed examples are in half-uncial letters, similar in character to the continental half-uncial MSS. of Roman type noticed above, that there can be no hesitation in deriving the Irish from the Roman writing. We have only to compare the Irish MSS. of the round type with the continental MSS. to be convinced of the identity of their styles of writing. There are unfortunately no means of ascertaining the exact period when this style of hand was first adopted in Ireland. Among the very earliest surviving examples none bears a fixed date; and it is impossible to accept the traditional ascription of certain of them to particular saints of
Ireland, as St Patrick and St Columba. Such traditions are notoriously unstable ground upon which to take up a position. But an examination of certain examples will enable the palaeographer to arrive at certain conclusions. In Trinity College, Dublin, is preserved a fragmentary copy of the Gospels (Nat.
MSS. Ireland, i. pl. ii.) vaguely assigned to a period from the 5th to the 7th century, and written in a round half-uncial hand closely resembling the continental hand, but bearing the general impress of its Irish origin. This MS, may perhaps be of the early part of the 7th century.

Fig. 40.—Gospels, 7th century.
(ad ilee deuntis respondens [dicit, Noli mihi molestus esse, iam ostitum clausum] est et pueri in cubiculo mecum [sunt])

Again, the Psalter (Nat. MSS. Ireland, i. pls. iii., iv.) traditionally ascribed to St Columba (d. 597), and perhaps of the 7th century, is a calligraphic specimen of the same kind of writing. The earliest examples of the continental half-uncial date back, as has been seen above, to the 5th century. Now the likeness between the earliest foreign and Irish MSS. forbids us to assume anything like collateral descent, as appears in the case of the national hands, although derived from the same source, would not independently develop in the same way, and it may accordingly be granted that the point of contact, or the period at which the Irish scribes copied and adopted the Roman half-uncial, was not very long, comparatively, before the date of the now earliest surviving examples. This would take us back at least to the 6th century, in which period there is sufficient evidence of literary activity in Ireland. The beautiful Irish calligraphy, ornamented with designs of marvellous intricacy and brilliant colouring, which is seen in full vigour at the end of the 7th century, indicates no small amount of labour bestowed upon the cultivation of writing as an ornamental art. It is indeed surprising that such excellence was so quickly developed. The Book of Kells has been justly acknowledged as the culminating example of Irish calligraphy (Nat. MSS. Ireland, i. pls. vii.-xvii.; Pal. Soc. pls. 35, 36). The text is written in the large solid half-uncial hand which is again seen in the Gospels of St Chad at Lichfield (Pal. Soc. pls. 20, 21, 35), and, in a smaller form, in the English-written Lindisfarne Gospels (see below). Having arrived at the calligraphic excellence just referred to, the hand appears to have been soon afterwards superseded, for general use, by the pointed; for the character of the large half-uncial writing of the Gospels of MacRegol, of about the year 800 (Nat. MSS. Ireland, i. pls. xxi.-xxiv.; Pal. Soc. pls. 90, 91), shows a very great deterioration from the vigorous writing of the Book of Kells, indicative of want of practice. Traces of the existence of the pointed hand are early. It is found in a fully developed stage in the Book of Kells itself (Pal. Soc. pl. 88). This form of writing, which may be termed the cursive hand of Ireland, differs in its origin from the national cursive hands of the Continent. In the latter the old Roman cursive has been shown to be the foundation. The Irish pointed hand, on the contrary, had nothing to do with the Roman cursive, but was simply a modification of the round hand, using the same forms of letters, but subjecting them to a lateral compression and drawing their limbs into points or hair-lines. As this process is found developed in the Book of Kells, its beginning may be fairly assigned to as early a time as the first half of the 7th century; but for positive date there is the same uncertainty as in regard to the first beginning of the round hand. The Book of Dimma (Nat. MSS. Ireland, i. pls. xvii., xix.) has been attributed to a scribe of about A.D. 650; but it appears rather to be of the 8th century, if we may judge by the analogy of English MSS. written in a similar hand. It is not in fact until we reach the period of the Book of Armagh (Nat. MSS. Ireland, pls. xxv.-xxx.), a MS. containing books of the New Testament and other matter, and written by Ferdomnach, a scribe who died in the year 844, that we are on safe ground. Here is clearly a pointed hand of the early part of the 9th century, very similar to the English pointed hand of Mercian charters of the same time. The MS. of the Gospels of MacDurnan, in the Lambeth Library (Nat. MSS. Ireland, i. pls. xxx., xxxi.) is an example of writing of the end of the 9th or beginning of the 10th century, showing a tendency to become more narrow and cramped. But coming down to the MSS. of the 11th or 12th centuries we find a change. The pointed hand by this time has become moulded into the angular and stereotyped form peculiar to Irish MSS. of the later middle ages. From the 12th to the 15th centuries there is a very gradual change. Indeed, a carefully written MS. of late date may very well pass for an example older by a century or more. A book of hymns of the 11th or 12th century (Nat. MSS. Ireland, i. pls. xxxii.-xxxvii.) may be referred to as a good typical specimen of the Irish hand of that period; and the Gospels of Macelbrighte, of A.D. 1138 (Nat. MSS. Ireland, i. pls. xi.-xli.; Pal. Soc. pl. 212), as a calligraphic one.

In Irish MSS. of the later period, the ink is black, and the vellum, as a general rule, is coarse and discoloured, a defect which may be attributed to inexperience in the art of preparing the skins and to the effects of climate.

When a school of writing attained to the perfection which marks the Irish school at an early date, so far in advance of other countries, it naturally followed that its influence should be felt beyond its own borders. How the influence of the Irish school asserted itself in England will be presently discussed. But on the Continent also Irish monks carried their civilizing power into different countries, and continued their native style of writing in the monasteries which they founded. At such centres as Luxeuil in France, Würzburg in Germany, St Gall in Switzerland, and Bobbio in Italy, they were as busy in the production of MSS. as they had been at home. At first such MSS. were no doubt as distinctly Irish in their character as if written in Ireland itself; but, after a time, as the bonds of connexion with that country were weakened, the form of writing would become rather traditional, and lose the elasticity of a native hand. As the national styles also which were practised around them became more perfected, the writing of the Irish houses would in turn be reacted on; and it is thus that the later MSS. produced in those hands can be distinguished. Archaic forms are traditionally retained, but the spirit of the hand dies and the writing becomes merely imitated.

English Writing.—In England there were two sources whence a national hand could be derived. From St Columba's foundation in Iona the Irish monks established monasteries in the northern parts of Britain; and in the year 635 the Irish missionary Aidan founded the see of Lindisfarne or Holy Isle, where there was established a school of writing destined to become famous. In the south of England the Roman missionaries also had brought into the country their own style of writing direct from Rome, and taught it in the newly founded monasteries. But their writing never became a national hand. Such a MS. as the Canterbury Psalter in the Cottonian Library (Pal. Soc. pl. 18) shows what could be done by English scribes in imitation of Roman uncialis; and the existence of so few early charters in the same letters (Pacs. of Anc. Charters, pt. i., Nos. 1, 2, 7), among the large number which have survived, goes to prove how limited was the influence of that form of writing. The famous MS. of the Bible known as the Codex Amiatinus, now at Florence, which was written in uncials at Jarrow in Northumbria, about the year 700, was almost certainly the work of foreign scribes. On the other hand, the Irish style made progress throughout England, and was adopted as the national hand, developing in course of time certain local peculiarities, and lasting as a distinct form of writing down to the time of the Norman Conquest. But, while English scribes at first copied their Irish models with faithfulness exactness, they soon learned to give to their writing the stamp of a national character, and imparted to it the elegance and strength which individualized the English hand for many centuries to come.
As in Ireland, so here we have to follow the course of the round hand as distinct from the pointed character. The earliest and most beautiful MS. of the former kind is the Lindisfarne Gospels (fig. 42) or "Durham Gospels" in the Cottonian Library (Pal. Soc. pls. 3–6, 22; Cat. Anc. MSS. pt. ii. pls. 8–11), said to have been written by Eadfrith, bishop of Lindisfarne, about the year 700. The text is in very exactly formed half-uncials, differing but slightly from the same characters in Irish MSS., and is glossed in the Northumbrian dialect by Aldred, a writer of the 8th century.

MSS. in the same solid half-uncial hand are still to be seen in the Chapter Library of Durham, this style of writing having been practised more especially in the north of England. But in addition to this calligraphic book-writing, there was also a lighter form of the round letters which was used for less sumptuous MSS. or for more ordinary occasions. Specimens of this hand are found in the Durham Cassiodorus (Pal. Soc. pl. 164), in the Canterbury Gospels (Pal. Soc. pl. 7; Cat. Anc. MSS. pt. ii. pls. 17, 18), the Epinal Glossary (E. Eng. Text Soc.), and in a few charters (Facsimiles Anc. Charters, pls. 1, 15; ii., 2, 3; Pal. Soc. 10), one of which, of A.D. 778, written in Wessex, is interesting as showing the extension of the round hand to the southern parts of England. The examples here enumerated are of the 8th and 9th centuries—the earlier ones being written in a free natural hand, and those of later date bearing evidence of decadence. Indeed the round hand was being rapidly displaced by the more convenient pointed hand, which was in full use in England in the middle of the 8th century. How late, however, the more calligraphic round hand could be continued under favouring circumstances is seen in the Liber Vitae or list of benefactors of Durham (Cat. Anc. MSS. pt. ii. pls. 25; Pal. Soc. pl. 238), the writing of which would from its beautiful execution, be taken for that of the 8th century; but we cannot say whether it was written for that purpose, or that it was written for the 8th century.

The pointed hand ran its course through the 8th, 9th, and 10th centuries, until English writing came under the influence of the foreign minuscule. The leading characteristics of this hand in the 8th century are regularity and breadth in the formation of the letters and a calligraphic contrast of heavy and light strokes—the hand being then at its best. In the 9th century there is greater lateral compression, although regularity and correct formation are maintained. But in the 10th century there are signs of decadence. New forms are introduced, and there is a disposition to be imitative. A test letter of this latter century is found in the letter a with obliquely cut top, Q.

The course of the progressive changes in the pointed hand may be followed in the Facsimiles of Ancient Charters in the British Museum and in the Facsimiles of Anglo-Saxon MSS. of the Rolls Series. The charters reproduced in these works have survived in sufficient numbers to enable us not only to form a fairly accurate knowledge of the criteria of their age, but also to recognize local peculiarities of writing. The Mercian scribes appear to have been very excellent penmen, writing a very graceful hand with much delicate play in the strokes. On the other hand the writing of Wessex was heavier and more straggling and is in such strong contrast to the Mercian hand that its examples may be easily detected with a little practice. Turning to books in which the pointed hand was employed, a very beautiful specimen, of the 8th century, is a copy of Bede's Ecclesiastical

History (fig. 42) in the University Library at Cambridge (Pal. Soc. pls. 139, 140), which has in a marked degree that breadth of style which has been referred to. Not much later is another example of the same work in the Cottonian Library (Pal. Soc. pl. 147; Cat. Anc. MSS. pt. ii. pl. 19), from which the following facsimile is taken.

For an example of the beginning of the 9th century, a MS. of miscellaneous, of A.D. 811–814, also in the Cottonian Library, may be referred to (Pal. Soc. pl. 165; Cat. Anc. MSS. pt. ii. Plate 24); and a very interesting MS. written in the Wessex style is the Digby MS. 63 of the middle of the century (Pal. Soc. pl. 168). As seen in the charter, the pointed writing of the 9th century is a larger size, and is rather more artificial and calligraphic. A very beautiful example of the book-hand of this period is found in the volume known as the Durham Ritual (Pal. Soc. pl. 240), which, owing to the care bestowed on the writing and the archaism of the style, might at first sight pass for a MS. of higher antiquity.

In the latter part of the 10th century the foreign set minuscule hand began to make its way into England, consequent on increased intercourse with the Continent and political changes which followed. In the charters we find the foreign and native hands on the same page: the body of the document, in Latin, in Carolingian minuscules; the boundaries of the land conveyed, in the English hand. The same practice was followed in books. The charter (in book form) of King Eadgar to New Minster, Winchester, A.D. 966 (Pal. Soc. pls. 46, 47), the Benedictional of Bishop Æthelwold of Winchester (pls. 142, 144) before A.D. 984, and the MS. of the Office of the Cross, A.D. 1012–1020 (pl. 60), also written in Winchester, are all examples of the use of the foreign minuscule for Latin. The change also which the national hand underwent at this period may certainly be attributed to this foreign influence. The pointed hand, strictly so-called, is replaced by a rounder or rather square character, with lengthened strokes above and below the line.

This style of writing becomes the ordinary English hand down to the time of the Norman Conquest. That event extinguished the national hand for official purposes—it disappears from charters; and the already established use of the Carolingian minuscule in Latin MSS. completed its exclusion as the hand-writing of the learned. It cannot, however, be doubted that it still lingered in those parts of the country where foreign influence did not at once penetrate, and that Englishmen still continued to write their own language in their own style of writing. But that the earlier distinctive national hand was in the 12th century, the writing of which is of the foreign type, although the English letter form, p, survived and continued in use down to the 15th century, when it was transformed to y.
LATIN WRITING. IV.—THE CAROLINGIAN REFORM AND THE MEDIEVAL MINUSCULE HAND

It has been stated above that in the Merovingian MSS. of the 8th century there was evident progress towards a settled minuscule book-hand which only required a masterly hand to fix it in a purified and calligraphic form. This was effected under Charlemagne, in whose reign the revival of learning naturally led to a reform in handwriting. An ordinance of the year 789 required the revision of Church books; and a more correct orthography and style of writing was the consequence. The abbey of St Martin de Tours was one of the principal centres from whence the reformation of the book-hand spread. Here, from the year 796 to 804, Alcuin of York presided as abbot; and it was specially under his direction that the Carolingian minuscule writing took the simple and graceful form which was gradually adopted to the exclusion of all other hands. In carrying out this reformation we may well assume that Alcuin brought to bear the results of the training which he had received in his youth in the English school of writing, which had attained to such proficiency, and that he was also beneficially influenced by the fine examples of the Lombard school which he had seen in Italy. In the new Carolingian minuscule all the uncoyness of the later Merovingian hand disappears, and the simpler forms of many of the letters found in the old Roman half-uncial and minuscule hands are adopted. The character of Carolingian writing through the 9th and early part of the 10th century is one of general uniformity, with a contrast of light and heavy strokes, the limbs of tall letters being clubbed or thickened at the head by pressure on the pen. As to characteristic letters (fig. 44), the α, following the old type, is, in the 9th century, still frequently open, in the form of ω; the bows of γ are open, the letter somewhat resembling the numeral 3; and there is little turning of the ends of letters, as m and n.

The 10th century the clubbing of the tall letters becomes less pronounced, and the writing generally assumes, so to say, a thinner appearance. But a great change is noticeable in the writing of the 11th century. By this time the Carolingian minuscule may be said to have put off its archaic form and to develop into the more modern character of small letter. It takes a more finished and accurate and more upright form, the individual letters being drawn with much exactness, and generally on a rather larger scale than before. This style continues to improve, and is reduced to a still more exact form of calligraphy in the 12th century, which for absolute beauty of writing is unsurpassed. In England especially (fig. 45) the writing of this century is particularly fine.

In MSS. of the 12th and 13th centuries more distinct writing of the 11th and 12th centuries is now replaced by a more cramped though still distinct hand, in which the letters are more linked together by connecting strokes, and are more laterally compressed. This style of writing is characteristic of the 13th century. But, while the book-hand of this period is a great advance upon that of a hundred years earlier, there is no tendency to a cursive style. Every letter is clearly formed, and generally on the old shapes. The particular letters which show weakness are those made of a succession of vertical strokes, as m, n, u. The new method of connecting these strokes, by turning the ends and running on, made the distinction of such letters difficult, as for example, in such a word as minu-mini. The ambiguity thus arising was partly obviated by the use of a small oblique stroke over the letter i, which, to mark the double letter, had been introduced as early as the 11th century. The dot on the letter entered into fashion in the 14th century.

FIG. 46.—Bible, 13th century.

(Eligite hodie quod placet cui seruorit potissimum debeat. Utrum dii quibus seruierunt patres uestri in mesopotamia, an diis amoreorium in quorum terrae habitationis. Ego autem et domus mea seruamus dominum. Respon- dite populis et ait, Abis nobis ur rellingam domini.)

In MSS. of the 12th century minuscule writing becomes slacker, and the consistency of formation of letters falters. There is a tendency to write more cursive and without raising the pen, as may be seen in the form of the letter a, of which the characteristic shape at this time is Α, with both bows closed, in contrast with the earlier a. In this century, however, the hand still remains fairly stiff and upright. In the 15th century it becomes very angular and more and more cursive, but is at first kept within bounds. In the course of the century, however, it grows more slack and deformed, and the letters become continually more cursive and misshapen. An exception, however, to this disintegration of minuscule writing in the later centuries is to be observed in church books. In these the old set hand of the 12th and 13th centuries was imitated and continued to be the liturgical style of writing.

It is impossible to describe within limited space, and without the aid of plentiful illustrations, all the varieties of handwriting which were developed in the different countries of western Europe, where the Carolingian minuscule was finally adopted to the exclusion of the earlier national hands. In each country, however, it acquired, in a greater or less degree, an individual national stamp which can generally be recognized and which serves to distinguish MSS. written in different localities. A broad line of distinction may be drawn between the writing of northern and southern Europe from the 12th to the 15th century. In the earlier part of this period the MSS. of England, northern France and the Netherlands are closely connected. Indeed, in the 12th and 13th centuries it is not always easy to decide as to which of the three countries a particular MS. may belong. As a rule, perhaps, English MSS. are written with more sense of gracefulness; those of the Netherlands in darker ink. From the latter part of the 13th century, however, national character begins to assert itself more distinctly. In southern Europe the influence of the Italian school of writing is manifest in the MSS. of the south of France in the 13th and 14th centuries, and also, though later, in those of Spain. That elegant roundness of letter which the Italian scribes seem to have inherited from the bold characters of the early papal chancery, and more recently from Lombardic models, was generally adopted in the book-hand of those districts. It is especially noticeable in calligraphic specimens, as in church books—the writing of Spanish MSS. in this style being distinguished by the blackness of the ink. The medieval minuscule writing of Germany stands apart. It never attained to the beauty of the hands of either the north or
the south which have been just noticed, and from its ruggedness and slow development German MSS. have the appearance of being older than they really are. The writing has also very commonly a certain slope in the letters which compares unfavourably with the upright and elegant hands of other countries. In western Europe generally the minuscule hand thus naturalized ran its course down to the time of the invention of printing, when the so-called black letter, or set hand of the 15th century in Germany and other countries, furnished models for the types. But in Italy, with the revival of learning, a more refined taste set in in the production of MSS., and scribes went back to an earlier time in search of a better standard of writing. Hence, in the first quarter of the 15th century, MSS. written on the lines of the Italian hand of the early 12th century begin to appear, and become continually more numerous. This revived hand was brought to perfection soon after the middle of the century, just at the right moment to be adopted by the early Italian printers, and to be perpetuated by them in their types.

English Cursive Charter-Hands.—It must also not be forgotten that by the side of the book-hand of the later middle ages there was the cursive hand of everyday use. This is represented in abundance in the large mass of charters and legal or domestic documents which remains. Some notice has already been taken of the development of the national cursive hands in the earliest times. From the 12th century onwards these hands settled into well defined and distinct styles peculiar to different countries, and passed through systematic changes which can be recognized as characteristic of particular periods. But, while the cursive hand thus followed out its own course, it was still subject to the same laws of change which governed the book-hand; and the letters of the two styles did not differ at any period in their organic formation. Confining our attention to the charter-hand, or court-hand, practised in England, a few specimens may be taken to show the principal changes which it developed. In the 12th century the official hand which had been introduced after the Norman Conquest is characterized by exaggeration in the strokes above and below the line, a legacy of the old Roman cursive, as already noted. There is also a tendency to form the tops of tall vertical strokes, as in b, h, l, with a notch or cleft. The letters are well made and vigorous, though often rugged.

FIG. 47.—Charter of Stephen, A.D. 1136-1139.

(et ministris et omnibus fideliibus suis Francisc et—
Regine uxoris mee et Eustachii filii—
mei dedi et concessi ecclesie Beate Marie)

As the century advances, the long limbs are brought into better proportion; and early in the 13th century a very delicate fine-stroked hand comes into use, the cleaving of the tops being now a regular system, and the branches formed by the cleft falling in a curve on either side. This style remains the writing of the reigns of John and Henry III.

FIG. 48.—Charter of Henry III., A.D. 1259.

(uniareis presentes litteras inspecturis salutem. Noueritis quod—
—ford et Essexe et Constabularium Angiae et Willemum de Fortibus—
ad iurandum in animam nostram in presencia nostra de pace)

Towards the latter part of the 13th century the letters grow rounder; there is generally more contrast of light and heavy strokes; and the cleft tops begin, as it were, to shed the branch on the left.

FIG. 49.—Charter of Edward I., A.D. 1303.

(More cum pertinente in mora quod vocatur Inkelesmore continentem—
se in longitudine per medium more illius ab uno capitae—
Abbas et Conventus aliquando tenuenter et quam praetatis Co—

In the 14th century the changes thus introduced made further progress, and the round letters and single-angled vertical strokes become normal through the first half of the century. Then, however, the regular formation begins to give way and angularity sets in. Thus in the reign of Richard II. we have a hand presenting a mixture of round and angular elements—the letters retain their breadth but lose their curves. Hence, by further decadence, results the angular hand of the 15th century, at first compact, but afterwards straggling and ill-formed.

FIG. 50.—English Charter, A.D. 1457.

(and fully to be ended, paying yerely the seid—
successors in hand here above were more that is—
next suying xiij. s. iii. d. by eveue porouscious.)

In concluding these remarks on the medieval cursive English writing, it is only necessary to remind the reader that the modern English cursive hand owes its origin to the general introduction into the west of the fine round Italian cursive hand of the 16th century—one of the notable legacies bequeathed to us by the wonderful age of the Renaissance.

This period is commonly referred to as the Palaeolithic Age or Palaeontology. The term "Palaeolithic" is derived from the Greek words παλαιός (palaios) meaning old, and λιθός (lithos) meaning stone, indicating that it relates to the use of stone tools and weapons which are commonly found in these ancient deposits. The Palaeolithic period is typically divided into the Lower Palaeolithic, Middle Palaeolithic, and Upper Palaeolithic. The Lower Palaeolithic is marked by the appearance of early stone tools and the use of fire, while the Middle Palaeolithic is characterized by more advanced tool-making techniques, such as the use of flint. The Upper Palaeolithic saw the development of more complex tool types, including the creation of bone and antler tools, and the use of hafted tools.

Animals. The period is characterized by flint implements of the rudest type and never polished. The fully authenticated remains of palaeolithic man are few, and discoveries are confined to certain areas, e.g., France and northern Italy. The reason is that interment appears not to have been practised by the river-drift hunters, and the only bones likely to be found would be those accidentally preserved in caves or rock-shelters. The first actual find of a palaeolithic implement was that of a rudely fashioned flint in a sandbank at Menecourt in 1841 by Boucher de Perthes. Further discoveries have resulted in the division of the Palaeolithic Age into various epochs or sequences according to the faunas associated with the implements or the localities where found. One classification makes three divisions for the epoch, characterized respectively by the existence of the bear, the mammoth and reindeer; another, two, marked by the prevalence of the mammoth and reindeer respectively. These divisions are, however, unsatisfactory, as the fauna relied on as characteristic must have existed synchronously. The four epochs or culture-sequences of G. de Mortillet have met with the most general acceptance. They are called from the places in France where the most typical finds of palaeolithic remains have been made, Chellian from Chelles, a few miles east of Paris; Mousterian from Moustiers; Aurignacian from the river Vézère, Dordogne; Solutrian from the cave at Solétré near Macôn; and Madelean from the rocky shelter of La Madeleine, Dordogne.

PALAEOLOGUS, a Byzantine family name which first appears in history about the middle of the 11th century, when George Palaeologus is mentioned among the prominent supporters of Nicephorus Botaniates, and afterwards as having helped to raise Alexius I. Comnenus to the throne in 1081; he is also noted for his brave defence of Durazzo against the Normans in that year. Michael Palaeologus, probably his son, was sent by Manuel II. Comnenus into Italy as ambassador to the court of Frederick I. in 1144; in the following year he took part in the campaign against William of Sicily, and died at Bari in 1155. A son or brother of Michael, named George, received from the emperor Michael the title of Sebasios, and was entrusted with several important missions; it is uncertain whether he ought to be identified with the George Palaeologus who took part in the conspiracy which deposed Isaac Angelus in favour of Alexius Angelus in 1195. Andronicus I Palaeologus was Great Domestic under Theodore Lascaris and John Vatatzes; his eldest son by Irene Palaeologina, Michael (q.v.), became the eighth emperor of that name in 1206, and was in turn followed by his son Andronicus II (1282-1328). Michael, the son of Andronicus, and associated with him in the empire, died in 1320, but left a son, Andronicus III, who reigned from 1328 to 1341; John VI. (1355-1391), Manuel II. (1391-1425) and John VII. (1425-1448) then followed in lineal succession; Constantine XII., the last emperor of the East (1445-1453), was the younger brother of John VII. Other brothers were Demetrius, prince of the Morea until 1460, and Thomas, prince of Achaea, who died at Rome in 1465. A daughter of Thomas, Zoe by name, married Ivan III. of Russia. A younger branch of the Palaeologoi held the principality of Monferrat from 1305 to 1333, when it became extinct.

See also EMPIRE, LATER, and articles on the separate rulers.

PALAEOLOGY (Gr. παλαιότης ancient, neut. παλαιόν, being, and λόγος discourse, science), the science of extinct forms of life. Like many other natural sciences, this study dawned among the Greeks. It was retarded and took false directions until the revival of learning in Italy. It became established as a distinct branch in the beginning of the 19th century, and somewhat later received the appellation "palaeontology," which was given independently by De Blainville and by Fischer von Waldheim about 1834. In recent years the science of vegetable palaeontology has been given the distinct name of Palaeobotany (q.v.), so that "palaeontology" among biologists mainly refers to zoology; but historically the two cannot be disconnected.

Palaeontology both borrows from and sheds light upon geology and other physical branches of the history of the earth,
PALAEONTOLOGY

of which, such as palaeogeography or palaeometeorology, is the more fascinating because of the large element of the unknown. The need for constructive imagination, the appeal to other branches of biological and physical investigation for supplementary evidence, and the necessity of constant comparison with the present aspects of nature. The task of the palaeontologist thus begins with the appearance of life on the globe, and ends in close relation to the studies of the archaeologist and historian as well as of the zoologist and botanist. That wealth of evidence which the zoologist enjoys, including environment in all its aspects and anatomy in its perfection of organs and tissues, the palaeontologist finds partially or wholly destroyed, and his highest art is that of complete restoration of both the past forms and past environments of life (see Plates I. and II.; figs. 1, 2, 3, 4, 5). The degree of accuracy in such anatomical and physiographic restorations from relatively imperfect evidence will always represent the state of the science and the degree of its approach toward being exact or complete. Progress in the science also depends upon the pursuit of palaeontology as zoology and not as geology, because it was a mere accident of birth which connected palaeontology so closely with geology.

In order to illustrate the grateful services which palaeontology through restoration may render to the related earth sciences let us imagine a vast continent of the past wholly unknown in its physical features, elevation, climate, configuration, but richly represented by fossil remains. All the fossil plants and animals of every kind are brought from this continent into a great museum; the latitude, longitude and relative elevation of each specimen are precisely recorded; a corps of investigators, having the most exact and thorough training in zoology and botany, and gifted with imagination, will soon begin to restore the geographic and physiographic outlines of the continent, its fresh, brackish and salt-water confines, its seas, rivers and lakes, its forests, uplands, plains, meadows and swamps, also to a certain extent the cosmic relations of this continent, the amount and duration of its sunshine, as well as something of the chemical constitution of its atmosphere and the waters of its rivers and seas; they will trace the progressive changes which took place in the outlines of the continent and its surrounding oceans, following the history of the dates by the records of the seas, their land and retreat of the seashore; they will outline the shoals and deeps of its border seas, and trace the barriers which prevented intermingling of the inhabitants of the various provinces of the continent and the surrounding seas. From a study of remains of the mollusca, brachiopoda and other marine organisms they will determine the shallow water (littoral) and deep water (abyssal) regions of the surrounding oceans, and the clear or muddy, salt, brackish or fresh character of its inland and marginal seas; and even the physical conditions of the open sea at the time will be ascertained.

In such manner Johannes Walther (Die Fauna der Solnhofener Platten Kalke Biomisch betrachtet. Festschrift zum 70ten Geburtstage von Ernst Haeckel, 1904) has restored the conditions existing in the lagoons and atoll reefs of the Jurassic sea of Solnhofen in Bavaria; he has traced the process of gradual accumulation of the coral mud now constituting the fine lithographic stones in the inter-reef region, and has recognized the periodic laying bare of the mud surfaces thus formed; he has determined the winds which carried the dust particles from the not far distant land and brought the insects from the adjacent Jurassic forests. Finally the presence of the flying lizards (Pterodactylus, Rhamphorhynchus) and the ancient birds (Archaeopteryx) is determined from remains in a most wonderful state of preservation in these ancient deposits.

Still another example of restoration, relating to the surface of a continent, may be cited. It has been discovered that at the beginning of the Eocene the lake of Killy occupied a vast area east of the present site of Paris, a water-course fell there in cascades, and Munier-Chalmas has reconstructed all the details of that singular locality; plants which loved moist places, such as Marchantia, Asplenium, the covered banks overshadowed by lindens, lauriers, magnolias and palms; there also were found the vine and the ivy; mosses (Fontinalis and Chara) sheltered the crinoid (Astacus); insects and even flowers have left their delicate impressions in the travertine which formed the borders of this lake. The Oligocene lake basin of Florissant, Colorado, has been reconstructed similarly by Samuel Hubbard Scudder and T. D. A. Cockerell, including the plants of its shores, the insects which lived upon them, the fluctuations of its level, and many other characteristics of this extinct water body, now in the heart of the arid region of the Rocky Mountains.

Such restorations are possible because of the intimate fitness of animals and plants to their environment, and because such fitness has distinguished certain forms of life from the Cambrian to the present time; the species have altogether changed, but the laws governing the life of certain kinds of organisms have remained exactly the same for the whole period of time assigned to the duration of life; in fact, we read the conditions of the past in a mirror of adaptation, often badly tarnished and incomplete owing to breaks in the palaeontological record, but constantly becoming more polished by discoveries which increase the understanding of life and its all-pervading relations to the non-life. Thereby palaeontology is the central principle of modern palaeontology in its most comprehensive sense.

This conception of the science and its possibilities is the result of very gradual advances since the beginning of the 19th century in what is known as the method of palaeontology. The history of this science, like that of all physical sciences, covers two parallel lines of development which have acted and reacted upon each other—namely, progress in exploration, research and discovery, and progress in philosophic interpretation. Progress in these two lines is by no means uniform; while, for example, palaeontology enjoyed a sudden advance early in the 19th century through the discoveries and researches of Cuvier, guided by his genius as a comparative anatomist, it was checked by his failure as a natural philosopher. The great philosophic impulse was that given by Darwin in 1859 through his demonstration of the theory of descent, which gave tremendous zest to the search for pedigrees (phylogeny) of the existing and extinct types of animal and plant life. In future the philosophic method of palaeontology must continue to advance step by step with every new interpretation. It would be a reproach to later generations if they did not progress as far beyond the philosophic status of Cuvier, Owen and even of Huxley and Cope, as the new materials represent an advance upon the material opportunities which came to them through exploration.

To set forth how best to do our thinking, rather than to follow the triumphs achieved in any particular line of exploration, and to present the point we have now reached in the method or principles of palaeontology, is the chief purpose of this article. The illustrations will be drawn both from vertebrate and invertebrate palaeontology. In the latter branch the author is wholly indebted to Professor Amadeus W. Grabau of Columbia University. The subject will be treated in its biological aspects, because the relations of palaeontology to historical and stratigraphic geology are more appropriately considered under the article Geology. See also, for botany, the article Palaeobotany. We may first trace in outline the history of the birth of palaeontological ideas, from the time of their first adumbration. But for full details reference must be made to the treatises on the history of the science cited in the bibliography at the end of the article.

1. First Historic Period

The scientific recognition of fossils as connected with the past history of the earth, from Aristotle (384-322 B.C.) to the beginning of the 19th century, in connexion with the rise of comparative anatomy and geology.—The dawn of the science covers the first observation of facts and the rudiments of true interpretation. Among the Greeks, Aristotle (384-322 B.C.) Xenophon (430-357 B.C.) and Strabo (63 B.C.—A.D. 24) knew of the existence of fossils and surmised in a crude way their relation to earth history. Similar prophetic views are found among certain Roman
Fig. 1.—An ichthyosaur (*T. quadriscissus*) containing in the body cavity the partially preserved skeletons of seven young, proving that the young of the animal developed within the maternal body and were brought forth alive; i.e. that the ichthyosaur was a viviparous animal. (Specimen presented to the American Museum of Natural History by the Royal Museum of Stuttgart through Professor Eberhard Fraas.)

Fig. 2.—A hypothetical pictorial restoration of the mother ichthyosaur accompanied by five of its newly born young from the information furnished by actual fossils.

(From a drawing by Charles R. Knight made under the direction of Professor Osborn.)

Fig. 3.—One of the most perfect of the many specimens discovered and prepared by Herr Bernard Hauff, and showing the extraordinary preservation of the epidermis of the ichthyosaur, which gives the complete contour of the body in silhouette, the outlines of the paddles, of the remarkably fish-like tail, and the great integumentary dorsal fin.

Materials for the Restoration of Ichthyosaurs.—This plate illustrates the exceptional opportunity afforded the palaeontologist through the remarkably preserved remains of Ichthyosaurs in the quarries of Holzmaden near Stuttgart, Württemberg, excavated for many years by Herr Bernard Hauff. (Illustrations reproduced by permission from specimens in the American Museum of Natural History, New York.)
Materials for the Restoration of Dinosaurs.—Carnivorous dinosaur (Allosaurus) of the Upper Jurassic period of North America, an animal closely related to the Megalosaurus type of England. The skeleton (fig. 4) was found nearly complete in the beds of the Morrison formation, Upper Jurassic of central Wyoming, U.S.A. Near it was discovered the posterior portion of the skeleton of a giant herbivorous dinosaur (Brontosaurus Marsh). It was observed that ten of the caudal vertebrae of the latter skeleton bore tooth marks and grooves corresponding exactly with the sharp pointed teeth in the jaw of the carnivorous dinosaur. This proved that the great herbivorous dinosaur had been preyed upon by its smaller carnivorous contemporary. Teeth of the carnivorous dinosaur scattered among the bones of the herbivorous dinosaur completed the line of circumstantial evidence. Upon this testimony the restoration (fig. 5) of the Megalosaurus has been drawn by Charles R. Knight under the direction of Professor Osborn.

writers. The pioneers of the science in the 16th and 17th centuries put forth anticipations of some of the well-known modern principles, often followed by recantations, through deference to prevailing religious or traditional beliefs. There were the retarding influences of the Mosaic account of sudden creation, and the belief that fossils represented relics of a universal deluge. There were crude medieval notions that fossils were "freaks" or "sports" or description in nature (lumen naturae), or that they represented failures of a creative force within the earth (a notion of Greek and Arabic origin), or that larger and smaller fossils represented the remains of races of giants or of pygmies (the mythical idea).

As early as the middle of the 17th century Leonardo da Vinci (1452-1519) recognized in seashells as well as in the teeth of marine fishes proofs of ancient sea-levels on what are now the summits of the Apennines. Successive observers in Italy, notably Fracastoro (1483-1553), Fabio Colonna (1567-1650 or 1650) and Nicolaus Steno (1638-1687), a Danish anatomist, professor in Padua, advanced the still embryonic science and set forth the principle of comparison of fossil with living forms. Near the end of the 17th century Martin Lister (1638-1712), examining the Mesozoic shell types of England, recognized the great similarity as well as the differences between these and modern species, and insisted on the need for close comparison of fossil and living shells, yet he clung to the old view that fossils were sports of nature. In Italy, where shells of the sub-Apennine formations were discovered in the extensive quarrying for the fortifications of cities, the close similarity between these Tertiary and the modern species soon led to the established recognition of their organic origin. In England Robert Hooke (1635-1703) held to the theory of extinction of fossil forms, and advanced the two most fertile ideas of deriving from fossils a chronology, or series of time intervals in the earth's history, and of primary changes of climate, to account for the former existence of tropical species in England.

The 18th century witnessed the development of these suggestions and the birth of many additional theories. Sir A. Geikie assigns high rank to Jean Étienne Guettard (1735-1780) for his treatises on fossils, although admitting that he had no clear idea of the sequence of formations. The theory of successive formations was soundly developing in the treatises of John Woodward (1665-1728) in England, of Antonio Vallisnièr (1661-1730) in Italy, and of Johann Gottlob Lehmann (d. 1757) in Germany, who distinguished between the primary, or unfossiliferous, and secondary or fossiliferous, formations. The beginnings of palaeogeography followed those of palaeometeorology. The Italian geologist Soldani distinguished (1758) between the fossil fauna of the deep sea and of the shore-lines. In the same year Johann Gesner (1709-1790) set forth the theory of a great period of time, which he estimated at 80,000 years, for the elevation of the shell-bearing levels of the Apennines to their present height above the sea. The brilliant French naturalist Georges Louis Leclerc, comte de Buffon (1707-1788), in Les Études de la nature, included in his vast speculations the theory of alternate submergence and emergence of the continents. Abraham Gottlob Werner (1750-1818), the famous exponent of the aqueous theory of earth formation, observed in successive geological formations the gradual approach to the forms of existing species.

II.—SECOND HISTORIC PERIOD

Invertebrate palaeontology founded by Lamarck, vertebrate palaeontology by Cuvier. Palaeontology connected with comparative anatomy by Cuvier. Invertebrate fossils employed for the definite division of all the great periods of time.—Although pre-evolutionary, this was the heroic period of the science, extending from the close of the 18th century to the publication of Darwin's Origin of Species in 1859. Among the pioneers of this period were the vertebrate zoologists and comparative anatomists Peter Simon Pallas, Pieter Camper and Johann Friedrich Blumenbach. Pallas (1741-1811) in his great journey (1768-1774) through Siberia discovered the vast deposits of extinct mammoths and rhinoceroses. Camper (1722-1789) contrasted (1777) the Pleistocene and recent species of elephants and Blumenbach (1752-1840) separated (1780) the mammoth from the existing species as Elephas primigenius. In 1795 Thomas Pennant (1726-1798) distinguished the American mastodon as Elephas americanus.

Political troubles and the dominating influence of Werner's speculations checked palaeontology in Germany, while under the leadership of Lamarck and Cuvier France came to the fore. J. B. Lamarck (1744-1829) was the founder of invertebrate palaeontology. The treatise which laid the foundation for all subsequent invertebrate palaeontology was his memoir, Sur les fossiles des environs de Paris... (1802-1806). Beginning in 1793 he boldly advocated evolution, and further elaborated five great principles—namely, the method of comparison of existing and extinct species, the broad sequence of formations and succession of epochs, the correlation of geological horizons by means of fossils, the climatic or environmental changes as influencing the development of species, the inheritance of the bodily modifications caused by change of habitat and habitat. As a natural philosopher he radically opposed Cuvier and was distinctly a precursor of uniformitarianism, advocating the gradual changes and variations, both in living forms and in their environment. His speculations on phylegony, or the descent of invertebrates and vertebrates, were, however, most fantastic and bore no relation to palaeontological evidence.

It is most interesting to note that William Smith (1760-1834), now known as the "father of historical geology," was born in the same year as Cuvier. Observing for himself (1794-1800) the stratigraphic value of fossils, he began to distinguish the great Mesozoic formations of England (1801). Cuvier (1760-1832) was famous as the founder of vertebrate palaeontology, and with Alexandre Brongniart (1770-1847) as the author of the first exact contribution to stratigraphic geology. Early trained as a comparative anatomist, the discovery of Upper Eocene mammals in the gypsum quarries of Montmartre found him fully prepared (1786), and in 1812 appeared his Recherches sur les ossemens fossiles, brilliantly written and constituting the foundation of the modern study of the extinct vertebrates. Invulnerable in exact anatomical description and comparison, he failed in all his philosophical generalizations, even in those strictly within the limits of anatomy. His famous "law of correlation," which by its apparent brilliancy added enormously to his prestige, is not supported by modern philosophical anatomy, and his services to stratigraphy were diminished by his generalizations as to a succession of sudden extinctions and renovations of life. His joint memoirs with Brongniart, Essai sur la géochronologie des environs de Paris avec une carte géognostique et des coupes de terrain (1808) and Description géologique des environs de Paris (1835) were based on the wonderful succession of Tertiary faunas in the rocks of the Paris basin. In Cuvier's defence Charles Depéret maintains that the extreme theory of successive extinctions followed by a succession of creations is attributable to Cuvier's followers rather than to the master himself. Depéret points also that we owe to Cuvier the first clear expression of the idea of the increasing organic perfection of all forms of life from the lower to the higher, and that, while he believed that extinctions were due to sudden revolutions of the surface of the earth, he also set forth the pregnant ideas that the renewal of animal life was by migration from other regions unknown, and that these migrations were favoured by alternate elevations and depressions which formed various land routes between great continents and islands. Thus Cuvier, following Buffon, clearly anticipated the modern doctrine of faunal migrations. His reactionary and retarding ideas as a special creationist and his advocacy of the cataclysmic theory of change exerted a baneful influence until overcome by the uniformitarianism of James Hutton (1726-1807) and Charles Lyell (1797-1875) and the evolutionism of Darwin.

The chief contributions of Cuvier's great philosophical opponent, Étienne Geoffroy St Hilaire (1772-1844), are to be found in his maintenance with Lamarck of the doctrine of the mutability of species. In this connexion he developed his
PALAEONTOLOGY

582

brought to light the marvellous fauna of the Siwalik hills of India, published in Fauna antiqua Sivalensis (London, 1843) and in the volumes of Falconer’s individual researches. The ancient life of the Atlantic border of North America was also becoming known through the work of the pioneer vertebrate palaeontologists Thomas Jefferson (1743–1826), Richard Harlan (1796–1843), Jeffries Wyman (1814–1874) and Joseph Leidy (1823–1891). This was followed by the revelation of the vast ancient life of the western half of the American continent, which was destined to revolutionize the science. The master works of Joseph Leidy began with the first-fruits of western exploration in 1847 and extended through a series of grand memoirs, culminating in 1874. Leidy adhered strictly to Cuvier’s exact descriptive methods, and while an evolutionist and recognizing clearly the genetic relationships of the horses and other groups, he never indulged in speculation.

The history of invertebrate palaeontology during the second period is more closely connected with the rise of historical geology and stratigraphy, especially with the settlement of the great and minor time divisions of the earth’s history. The path-breaking works of Lamarck were soon followed by the monumental treatise of Géraud Paul Deshayes (1795–1875) entitled Descriptions des coquilles fossiles des environs de Paris (1824–1837), the first of a series of great contributions by this and other authors. These and other early monographs on the Tertiary shells of the Paris basin, of the environs of Bordeaux, and of the sub-Apennine formations of Italy, brought out the striking distinctness of these faunas from each other and from other molluscan faunas. Recognition of this threefold character led Deshayes to establish a threefold division of the Tertiary based on the percentage of molluscs belonging to types now living found in each. To these divisions Lyell gave in 1833 the names Eocene, Miocene and Pliocene.

James Hutton (1726–1797) had set forth (1788) the principle that during all geological time there has been no essential change in the character of events, and that uniformity of law is perfectly consistent with mutability in the results. Lyell marshalled all the observations he could collect in support of this principle, teaching that the present is the key to the past, and arraying all obtainable evidence against the cataclysmic theories of Cuvier. He thus exerted a potent influence on palaeontology through his persistent advocacy of uniformitarianism, a doctrine with which Lamarck should also be credited.

As among the vertebrates, materials were accumulating rapidly for the great generalizations which were to follow in the third period. De Blainville added to the knowledge of the shells of the Paris basin; Giovanni Battista Brocchi (1772–1826) in 1814, and Luigi Bellardi (1818–1869) and Giovanni Michelotti (born 1812) in 1840, described the Pliocene molluscs of the sub-Appenine formation of Italy; from Germany and Austria appeared the epoch-making works of Heinrich Ernst Beyrich (1815–1856) and of Moritz Hoernes (1815–1868). We shall pass over here the labours of Adam Sedgwick (1785–1873) and Sir Roderick Murchison (1792–1871) in the Palaeozoic of England, which because of their close relation to stratigraphy more properly concern geology; but must mention the grand contributions of Joachim Barrande (1799–1883), published in his Système silurien du centre de la Bohême, the first volume of which appeared in 1852. While establishing the historic divisions of the Silurian in Bohemia, Barrande also propounded his famous theory of “colonies,” by which he attempted to explain the aberrant occurrence of strata containing animals of a more advanced stage among strata containing earlier and more primitive faunas; his assumption was that the second fauna had migrated from an unknown neighbouring region. It is proved that the specific instances on which Barrande’s generalizations were founded were due to his misinterpretation of the overturned and faulted strata, but his conception of the simultaneous existence of two faunas, one of more ancient and one of more modern type, and of their alternation in a given area, was based on sound philosophical principles and has been confirmed by more recent work.

special theory of saltations, or of sudden modifications of structure through changes of environment, especially through the direct influences of temperature and atmosphere. He clearly set forth also the phenomena of analogous or parallel adaptation.

It was Alcide Dessalines d’Orbigny (1802–1857) who pushed to an extreme Cuvier’s ideas of the fixity of species and of successive extinguishments, and finally developed the wild hypothesis of twenty-seven distinct creations. While these views were current in France, exaggerating and surpassing the thought of Cuvier, they were strongly opposed in Germany by such authors as Ernst Friedrich von Schlotheim (1764–1832) and Heinrich Georg Bronn (1800–1862); and the latter demonstrated that certain species actually pass from one formation to another.

In the meantime the foundations of palaeobotany were being laid (1804) by Ernst Friedrich von Schlotheim (1764–1832), (1811) by Kaspar Maria Sternberg (1791–1838) and (1838) by Théophile Brongniart (1802–1877). Following Cuvier’s Recherches sur les ossements fossiles, the rich succession of Tertiary mammalian life was gradually revealed to France through the explorations and descriptions of such authors as Croizet, Jobert, de Christol, Eymar, Pomel and Lartet, during a period of rather dry, systematic work, which included, however, the broader generalizations of Henri Marie Ducrotay de Blainville (1778–1850), and culminated in the comprehensive treatises on Tertiary palaeontology of Paul Gervais (1816–1879). Extending the knowledge of the extinct mammals of Germany, the principal contributors were Georg August Goldfuss (1782–1848), Georg Friedrich von Jaeger (1785–1860), Felix F. Pileneiger (1807–1873) and Johann Jacob Kaup (1803–1873). As Cuvier founded the palaeontology of mammals and reptiles, so Louis Agassiz’s epoch-making works Recherches sur les poissons fossiles (1833–1845) laid the secure foundations of paleoichthyology, and were followed by Christian Heinrich Pander’s (1794–1865) classic memoirs on the fossil fishes of Russia. In philosophy Agassiz was distinctly a disciple of Cuvier and supporter of the doctrine of special creation, and to a more limited extent of cataclysmic extinctions. Animals of the next higher order, the amphibians of the coal measures and the Permian, were first comprehensively treated in the masterly memoirs of Christian Erich Hermann von Meyer (1801–1869) beginning in 1829, especially in his Beiträge zur Petrefaktenkunde (1829–1830) and his Zur Fauna der Vorel (4 vols., 1834–1860).

Successive discoveries gradually revealed the world of extinct Reptilia; in 1821 Charles König (1784–1851), the first keeper of the mineralogical collection in the British Museum, described Ichthyosaurus from the Jurassic; in the same year William Daniel Conybeare (1787–1857) described Plesiosaurus; and a year later (1822) Mosasaurus; in 1824 William Buckland described the great carnivorous dinosaur Megalosaurus; while Gideon Algernon Mantell (1790–1852) in 1848 announced the discovery of Iguanodon. Some of the fossil Reptilia of France were made known through St Hilaire’s researches on the Crocodilia (1831), and those of J. A. Deslongchamps (1794–1857) and his son on the telesaurs, or long-nosed crocodiles. Materials accumulated far more rapidly, however, than the power of generalization and classification. Able as von Meyer was, his classification of the Reptilia failed because based upon the single adaptive characters of foot structure. The reptiles awaited a great classifier, and such a one appeared in England in the person of Sir Richard Owen (1804–1892), the direct successor of Cuvier and a comparative anatomist of the first rank. Non-committal as regards evolution, he vastly broadened the field of vertebrate palaeontology by his descriptions of the extinct fauna of England, of South America especially, of the great edentates revealed by the voyage of the “Beagle,” of Australia (the ancient and modern marsupials) and of New Zealand (the great struthious birds). His contributions on the Mesoicoic reptiles of Great Britain culminated in his complete rearrangement and classification of this group, one of his greatest services to palaeontology. Meanwhile the researches of Hugh Falconer (1808–1865) and of Proby Thomas Cautley (1802–1871) in the sub-Himalayas
The greatest generalization of this second period, however, was that partly prepared for by d'Orbigny, as will be more fully explained later in this article, and clearly expressed by Agassiz—namely, the law of repetition of ancestral stages of life in the course of the successive stages of individual development. This law of recapitulation, subsequently termed the "biogenetic law" by Ernst Haeckel, was the greatest philosophic contribution of this period, and proved to be not only one of the bulwarks of the evolution theory but one of the most important principles in the method of palaeontology.

On the whole, as in the case of vertebrate palaeontology, the pre-Darwinian period of invertebrate palaeontology was one of rather dry systematic description, in which, however, the applications of the science gradually extended to many regions of the world and to all divisions of the kingdom of invertebrates.

III.—THIRD HISTORIC PERIOD

Beginning with the publication of Darwin's great works, "Narrative of the Surveying Voyages of H.M.S. 'Adventure' and 'Beagle'" (1839), and "On the Origin of Species by Means of Natural Selection" (1859), a review of the two first classic works on palaeontology, and of their influence proves that he was the founder of modern palaeontology. Principles of descent and other applications of uniformitarianism which had been struggling in the writings of Lamarck, St Hilaire and de Blainville here found their true interpretation, because the geological succession, the rise, the migrations, the extinctions, were all connected with the grand central idea of evolution from primordial forms.

A close study of the exact modes of evolution and of the philosophy of evolution is the distinguishing feature of this period. It appears from comparison of the work in the two great divisions of vertebrate and invertebrate palaeontology made for the first time in this article that in accuracy of observation and in close philosophical analysis of facts the students of invertebrate palaeontology led the way. This was due to the much greater completeness and abundance of material afforded among invertebrate fossils, and it was manifested in the demonstration of two great principles or laws: first, the law of recapitulation, which is found in most ideal expression in the shells of invertebrates; second, the law of direct genetic succession through very gradual modification. It is singular that the second law is still ignored by many zoologists. Both laws were of paramount importance, as direct evidence of Darwin's theory of descent, which, it will be remembered, was at the time regarded merely as a hypothesis. Nevertheless, the tracing of phylogeny, or direct lines of descent, suddenly began to attract far more interest than the naming and description of species.

The Law of Recapitulation. Acceleration. Retardation.—This law, that in the stages of growth of individual development (ontogeny), an animal repeats the stages of its ancestral evolution (phylogeny) was, as we have stated, anticipated by d'Orbigny. He recognized the fact that the shells of mollusces, which grow by successive additions, preserve unchanged the whole series of stages of their individual development, so that each shell of a Cretaceous ammonite, for example, represents five stages of progressive modification as follows: the first is the *periode embryonnaire*, during which the shell is smooth; the second, third represent periods of elaboration and ornamentation; the fourth is a period of initial degeneration; the fifth and last a period of degeneration when ornamentation becomes obsolete and the exterior smooth again, as in the young. D'Orbigny, being a special creationist, failed to recognize the bearing of these individual stages on evolution. Alpheus Hyatt (1838–1902) was the first to discover (1866) that these changes in the form of the ammonite shell agreed closely with those which had been passed through in the ancestral history of the ammonites. In an epoch-making essay, *On the Parallelism between the Different Stages of Life in the individual and those in the entire group of the Molluscan Order Tetrabranchiata* (1866), and in a number of subsequent memoirs, among which *Genesis of the Arietidae* (1886) and *Phylogeny of an Acquired Characteristic* (1894) should be mentioned, he laid the foundations, by methods of the most exact analysis, for all future recapitulation work of invertebrate palaeontologists. He showed that from each individual shell of an ammonite the entire ancestral series may be reconstructed, and that, while the earlier shell-whorls retain the characters of the adults of preceding members of the series, a shell in its own adult stage adds a new character, which in turn becomes the pre-adult character of the types which will succeed it; finally, that this comparison between the revolutions of the life of an individual and the life of the entire order of ammonites is wonderfully harmonious and precise. Moreover, the last stages of individual life are prophetic not only of future rising and progressing derivatives, but in the case of senile individuals of future declining and degradational series.

Thus the recapitulation law, which had been built up independently from the observations and speculations on vertebrates by Lorenz Oken (1779–1851), Johann Friedrich Meckel (1781–1833), St Hilaire, Karl Ernst von Baer (1792–1876) and others, and had been applied (1842–1843) by Karl Vogt (1817–1895) and Agassiz, in their respective fields of observation, to comparison of individual stages, with the adults of the same group in preceding geological periods, furnished the key to the determination of the ancestry of the invertebrates generally.

Hyatt went further and demonstrated that ancestral characters are passed through by successive descendants at a more and more accelerated rate in each generation, thus giving time for the appearance of new characters in the adult. His "law of acceleration" together with the complementary "law of retardation," or the slowing up in the development of certain characters (first propounded by E. D. Cope), was also a philo-

sophic contribution of the first importance (see fig. 6 and Plate III, fig. 7).

In the same year, 1866, Franz Martin Hilgendorf (1839– ) studied the shells of *Planorbis* from the Miocene lake basin underlying the present village of Steinheim in Württemberg, and introduced the method of examination of large numbers of individual specimens, a method which has become of prime importance in the science. He discovered the actual transmutations in direct genetic series of species on the successive deposition levels of the old lake basin. This study of direct genetic series marked another great advance, and became possible in invertebrate palaeontology long before it was introduced among the vertebrates. Hyatt, in a re-examination of the Steinheim deposits, proved that successive modifications occur at the same level as well as in vertical succession. Melchior Neumayr (1845–1890) and C. M. Paul similarly demonstrated genetic series of *Paludina* (*Vivipora*) in the Pliocene lakes of Slavonia (1875).

The Mutations of Waagen. Orthogenes.—In 1889 Wilhelm Heinrich Waagen (1845–1900) entered the field with the study of *Ammonites subradiatus*. He proposed the term "mutations" for the minute progressive changes of single characters in definite directions as observed in successive stratigraphic levels. Even when seen in minute features only he recognized them as constant progressive characters or "chronologic varieties" in
PALAEONTOLOGY

contrast with contemporaneous or "geographic varieties," which he considered inconstant and of slight systematic value. More recent analysis has shown, however, that certain modifications observed within the same stratigraphic level are really grades of mutations which show divergences comparable to those found in successive levels. The collective term "mutation," as now employed by palaeontologists, signifies a type modified to a slight degree in one or more of its characters along a progressive or definite line of phyletic development. The term "mutation" also applies to a single new character and for distinction¹ may be known as "the mutation of Waagen." This definitely directed evolution, or development in a few determinable directions, has since been termed "orthogenetic evolution," and is recognized by all workers in invertebrate palaeontology and phylogeny as fundamental because the facts of invertebrate palaeontology admit of no other interpretation.

Among the many who followed the method of attack first outlined by Hyatt, or who independently discovered his method, only a few can be mentioned here—namely, Waagen (1869), Neumayr (1871), Württemberger (1880), Branco (1880), Mojsisovics (1882), Buckman (1883), Kampinsky (1886), Jackson (1890), Beecher (1890), Perrin-Smith (1897), Clarke (1898) and Grabau (1904). Melchior Neumayr, the great Austrian palaeontologist, especially extended the philosophic foundations of modern invertebrate palaeontology, and traced a number of continuous genetic series (formenreihen) in successive horizons. He also demonstrated that mutations have this special or distinctive character, that they repeat in the same direction without oscillation or retrogression. He expressed great reserve as to the causes of these mutations. He was the first to attempt a comprehensive treatment of all invertebrates from the genetic point of view; but unfortunately his great work, entitled Die Stämme des Thierreichs (Vienna and Prague, 1886), was uncompleted.

The absolute agreement in the results independently obtained by these various investigators, the interpretation of individual development as the guide to phyletic development, the demonstration of continuous genetic series, each mutation falling into its proper place and all showing a definite direction, constitute contributions to biological philosophy of the first importance, which have been little known or appreciated by zoologists because of their publication in monographs of very special character.

Vertebrate Palaeontology after Darwin.—The impulse which Darwin gave to vertebrate palaeontology was immediate and unbounded, finding expression especially in the writings of Thomas Henry Huxley (1825–1895) in England, of Jean Albert Gaudry (b. 1827) in France, of America of Edward Drinker Cope (1840–1897) and Othniel Charles Marsh (1831–1899). Fine examples of the spirit of the period as applied to extinct Mammalia are Gaudry's Animaux fossiles et géologie de l'Attique (1862) on the Upper Miocene fauna of Pikermi near Athens, and the remarkable memoirs of Vladimir Onufrieievich Kowalevsky (1844–1885), published in 1873. These works swept aside the dry traditional formalism which had been accumulating in France and Germany. They breathed the new spirit of the recognition of adaptation and descent. In 1867–1872 Milne Edwards published his memoirs on the Miocene birds of central France. Huxley's development of the method of palaeontology should be studied in his collected memoirs (Scientific Memoirs of Thomas Henry Huxley, 4 vols., 1898). In Kowalevsky's Versuch einer natürlichlichen Classification der Fossilien Haithiere (1873) we find a model union of detailed inductive study with theory and working hypothesis. All these writers attacked the problem of descent, and published preliminary phylogenies of such animals as the horse, rhinoceros and elephant, which time has proved to be of only general value and not at all comparable to the exact phylogenetic series which were being established by invertebrate palaeontologists. Phylectic gaps began to be filled in this general way, however, by discovery, especially through remarkable discoveries in North America by Leidy, Cope and Marsh, and the ensuing phylogenies gave enormous prestige to palaeontology.

Cope's philologic contributions to palaeontology began in 1868 (see essays in The Origin of the Fittest, New York, 1887, and The Primary Factors of Organic Evolution, Chicago, 1896) with the independent discovery and demonstration among vertebrates of the laws of acceleration and retardation. To the law of "recapitulation" he unfortunately applied Hyatt's term "parallelism," a term which is used now in another sense. He especially pointed out the laws of the "extinction of the specialized" and "survival of the non-specialized" forms of life, and challenged Darwin's principle of selection as an explanation of the origin of adaptations by saying that the "survival of the fittest" does not explain the "origin of the fittest." He personally sought to demonstrate such origin, first, in the existence of a specific internal growth force, which he termed biologic force, and second in the direct inheritance of acquired mechanical modifications of the teeth and feet. He thus revived Lamarck's views and helped to found the so-called neo-Lamarckian school in America. To this school A. Hyatt, W. H. Dall and many other invertebrate palaeontologists contributed.

History of Discovery. Vertebrates.—In discovery the theatre of interest has shifted from continent to continent, often in a sensational manner. After a long period of gradual revelation of the ancient life of Europe, extending eastward to Greece, eastern Asia and to Australia, attention became centred on North America, especially on Rocky Mountain exploration. New and unheard-of orders of amphibians, reptiles and mammals came to the surface of knowledge, revolutionizing thought, demonstrating the evolution theory, and solving some of the most important problems of descent. Especially noteworthy was the discovery of birds with teeth both in Europe (Archaeopteryx) and in North America (Hesperornis), of Eocene stages in the history of the horse, and of the giant dinosauria of the Jurassic and Cretaceous in North America. Then the stage of novelty suddenly shifted to South America, where after the pioneer labours of Darwin, Owen and Burmeister, the field of our knowledge was suddenly and vastly extended by explorations by the brothers Ameghino (Carlos and Florentino). We were in the midst of more thorough examination of the ancient world of Patagonia, of the Pampean region and of its submersed sister continent Antarctica, when the scene shifted to North Africa through the discoveries of Hugh J. L. Beadnell and Charles W. Andrews. These latter discoveries supply us with the ancestry of the elephants and many other forms. They round out our knowledge of Tertiary history, but leave the problems of the Cretaceous mammals and of their relations to Tertiary mammals still unsolved. Similarly, the Mesozoic reptiles have been traced successively to various parts of the world from France, Germany, England, to North America and South America, to Australia and New Zealand and to northern Russia, from Cretaceous times back into the Permian, and by latest reports into the Carboniferous.

Discovery of Invertebrates.—The most striking feature of exploration for invertebrates, next to the world-wide extent to which exploration has been carried on and results applied, is the great numbers of times the molluscs were considered as appearing on the limits of the Cambrian and Ordovician; but Charles D. Walcott has described a tiny lamellibranch (Molluscoidea) from the inferior Cambrian, and he reports the gastropod (?) genus Chauria from the pre-Cambrian. Cephalopod molluscs have been traced back to the straight-shelled nautiloids of the genus Valvorthella, while ancient ammonites have been found in the inferior Permian of the Continent and by American palaeontologists in the true coal measures. Similarly, early forms of the crustacean sub-class Merostomata have been traced to the pre-Cambrian of North America.

Recent discoveries of vertebrates are of the same significance, the most primitive fishes being traced to the Ordovician or base of the Silurian,² which proves that we shall discover more.

¹ The Dutch botanist, De Vries, has employed the term in another sense, to mean a slight jump or saltation.

² Professor Bashford Dean doubts the fish characters of these Ordovician Rocky Mountain forms. Fresh admits their fish character but considers the rocks infaulted Devonic.
This series of feet represents the evolutionary succession from the Eocene *Hypohippus* (1) to the modern *Equus* (6) seen in front and in side view. The top bone is the os calcis, or hock bone, to which the *tendon Achilles* is attached. The bottom bone is the terminal phalanx which is inserted in the heart of the hoof.

The stages are as follows:

5. *Neohipparion*, Upper Miocene.

The evolution consists first in progressive increase in size, second, in the acceleration of the median digit and retardation of the lateral digits, the latter becoming more and more elevated from the ground until finally in *Equus* (6) they are the lateral splints, which in the embryonic condition have vestigial cartilages attached representing the last traces of the lateral phalanges.

ancient chordates in the Cambrian or even pre-Cambrian. Thus all recent discovery tends to carry the centres of origin and of dispersal of all animal types farther and farther back in geological time.

IV.-RELATIONS OF PALEONTOLOGY TO OTHER PHYSICAL EARTH SCIENCES

Geology and Palaeophysiography.—Fossils are not absolute timekeepers, because we have little idea of the rate of evolution; they are only relative timekeepers, which enable us to check off the period of deposition of one formation with that of another. Huxley questioned the time value of fossils, but recent research has tended to show that identity of species and of mutations is, on the whole, a guide to synchrony, though the general range of vertebrate and invertebrate life as well as of plant life is generally necessary for the establishment of approximate synchronism. Since fossils afford an immediate and generally a decisive clue to the mode of deposition of rocks, whether marine, lacustrine, fluviatile, flood plain or aeolian, they lead us naturally into palaeophysiography. Instances of marine and lacustrine analysis have been cited above. The analysis of continental faunas into those inhabiting rivers, lowlands, forests, plains or uplands, affords a key to physiographic conditions all through the Tertiary. For example, the famous bone-beds of the Oligocene of South Dakota have been analysed by W. D. Matthew, and are shown to contain fluviatile or channel beds with water and river-living forms, and neighbouring flood-plain sediments containing remains of plains-living forms. Thus we may complete the former physiographic picture of a vast fast plain east of the Rocky Mountains, traversed by slowly meandering streams.

As already intimated, our knowledge of palaeoecology, or of past climates, is derivable chiefly from fossils. Suggested two centuries ago by Robert Hooke, this use of fossils has in the hands of Barrande, Neumayr, the marquis de Saporta (1869), Oswald Heer (1854–1890), and an army of followers developed into a sub-science of vast importance and interest. It is true that a great variety of evidence is afforded by the composition of the rocks, that glaciers have left their traces in glacial scratchings and transported boulders, also that proofs of arid or semi-arid conditions are found in the reddish colour of rocks in certain portions of the Palaeozoic, Trias and Eocene; but fossils afford the most precise and conclusive evidence as to the past history of climate, because of the fact that adaptations to temperature have remained constant for millions of years. All conclusions derived from the various forms of animal and plant life should be scrutinized closely and compared. The brilliant theories of the palaeobotanist, Oswald Heer, as to the extension of a sub-tropical climate to Europe and even to extreme northern latitudes in Tertiary time, which have appealed to the imagination and found their way so widely into literature, are now challenged by J. W. Gregory (Geomorphological Variations in their Extent and Cause in the United States Geological Congress, Mexico, 1906), who holds that the extent of climatic changes in past times has been greatly exaggerated.

It is to palaeogeography and zoogeography in their reciprocal relations that palaeontology has rendered the most unique services. Geographers are practically helpless as historians, and problems of the former elevation and distribution of the land and sea masses depend for their solution chiefly upon the palaeontologist. With good reason geographers have given reluctant consent to some of the bold restorations of ancient continental outlines by palaeontologists; yet some of the greatest achievements of recent science have been in this field. The concurrence of botanical (Hooker, 1847), zoological, and finally of palaeontological evidence for the reconstruction of the continent of Antarctica, is one of the greatest triumphs of biological investigation. To the evidence advanced by a great number of authors comes the clinching testimony of the existence of a number of varieties of Australian marsupials in Patagonia, as originally discovered by Ameghino and more exactly described by members of the Princeton Patagonian expedition staff; while the fossil shells of the Eocene of Patagonia as analysed by Ortmann give evidence of the existence of a continuous shoreline, or at least of shallow-water areas, between Australia, New Zealand and South America. This line of hypothesis and demonstration is typical of the palaeogeographic methods generally—namely, that vertebrate palaeontologists, impressed by the sudden appearance of extinct forms of continental life, demand land connexion or migration tracts from common centres of origin and dispersal, while the invertebrate palaeontologist alone is able to restore ancient coast-lines and determine the extent and width of these tracts. Thus has been built up a distinct and most important branch. The great contributors to the palaeogeography of Europe are Neumayr and Eduard Suess (b. 1831), followed by Frech, Canu, de Lapparent and others. Neumayr was the first to attempt to restore the grander earth outlines of the earth as a whole in Jurassic times. Suess outlined the ancient relations of Africa and Asia through his “Gondwana Land,” a land mass practically identical with the “Lemuria” of zoologists. South American palaeogeography has been traced by von Hrbing into a northern land mass, “Archeelen,” and a southern mass, “Archiplata,” the latter at times united with anantarctic continent. Following the pioneer studies of Dana, the American palaeontologists and stratigraphers Bailey Willis, John M. Clarke, Charles Schuchert and others have re-entered the study of the Palaeozoic geography of the North American continent with work of astonishing precision.

Zoogeography.—Closely connected with palaeogeography is zoogeography, the animal distribution of past periods. The science of zoogeography, founded by Humboldt, Edward Forbes, Huxley, P. L. Schater, Alfred Russel Wallace and others, largely upon the present distribution of animal life, is now encountering through palaeontology a new and fascinating series of problems. In brief, it must connect living distribution with distribution in past time, and develop a system which will be in harmony with main facts of zoology and palaeontology. The theory of past migrations from continent to continent, suggested by Cuvier to explain the replacement of the animal life which had become extinct through sudden geologic changes, was prophetic of one of the chief features of modern method—namely, the tracing of migrations. With this has been connected the theory of “centres of origin” or of the geographic regions where the chief characters of great groups have been established. Among invertebrates Barrande’s doctrine of centres of origin was applied by Hyatt to the genesis of the Arctiidae (1880); after studying thousands of individuals from the principal deposits of Europe he decided that the cradles of the various branches of this family were the basins of the Côte d’Or and southern Germany. Ortmann has traced the centre of dispersal of the fresh-water Crawfish genera Camburus, Potamobius and Cambacrodes to eastern Asia, where their common ancestors lived in Cretaceous times. Similarly, among vertebrates the method of restoring past centres of origin, largely originating with Cope and Marsh, has developed into a most distinct and important branch of historical work. This branch of the science has reached the highest development in its application to the history of the extinct mammalia of the Tertiary through the original work of Cope and Henri Filhol, which has been brought to a much higher degree of exactness recently through the studies of H. F. Osborn, Charles Depéret, W. D. Matthew and H. G. Stehlin.

V.-RELATIONS OF PALEONTOLOGY TO OTHER ZOOLOGICAL METHODS

Systematic Zoology.—It is obvious that the Linnaean binomial terminology and its subsequent trinomial refinement for species, sub-species, and varieties was adapted to express the differences between animals as they exist to-day, distributed contemporaneously over the surface of the earth, and that it is wholly inadequate to express either the minute gradations of successive generic series or the branchings of a genetically connected chain of life. Such gradations, termed “mutations” by Waagen, are distinguished, as observed, in single characters; they are the
nuances, or grades of difference, which are the more gradual the more finely we dissect the geologic column, while the terms species, sub-species and variety are generally based upon a sum of changes in several characters. Thus palaeontology has brought to light an entirely new nomenclatural problem, which can only be solved by resolutely adopting an entirely different principle.

**Embryology and Ontogeny.**—In following the discovery of the law of recapitulation among palaeontologists we have clearly stated the chief contribution of palaeontology to the science of ontogeny—namely, the correspondences and differences between

This revolution may be accomplished by adding the term "mutation ascending" or "mutation descending" for the minute steps of transformation, and the term phylum, as employed in Germany, for the minor and major branches of genetic series. Bit by bit mutations are added to each other in different single characters until a sum or degree of mutations is reached which no zoologist would hesitate to place in a separate species or in a separate genus.

The minute gradations observed by Hyatt, Waagen and all invertebrate palaeontologists, in the hard parts (shells) of molluscs, &c., are analogous to the equally minute gradations observed by vertebrate palaeontologists in the hard parts of reptiles and mammals. The mutations of Waagen may possibly, in fact, prove to be identical with the "definite variations" or "rectigradations" observed by Osborn in the teeth of mammals. For example, in the grinders of Eocene horses (see Plate III., fig. 8; also fig. 9) in a lower horizon a cusp is a dumbbroad in shadowy form, in a slightly higher horizon it is visible, in a still higher horizon it is full-grown; and we honour this final stage by assigning to the animal which bears it a new specific name. When a number of such characters accumulate, we further honour them by assigning a new generic name. This is exactly the nomenclature system laid down by Owen, Cope, Marsh and others, although established without any understanding of the law of mutation. But besides the innumerable characters which are visible and measurable, there are probably thousands which we cannot measure or which have not been discovered, since every part of the organism enjoys its gradual and independent evolution. In the face of the continuous series of characters and types revealed by palaeontology, the Linnaean terminology, the individual order of development and the ancestral order of evolution. The mutual relations of palaeontology and embryology and comparative anatomy are means of determining the ancestry of animals are most interesting. In tracing the phylogeny, or ancestral history of organs, palaeontology affords the only absolute criterion on the successive evolution of organs in time as well as of (progressive) evolution in form. From comparative anatomy alone it is possible to arrange a series of living forms which, although structurally a convincing array because placed in a graded series, may be, nevertheless, in an order inverse to that of the actual historical succession. The most marked case of such inversion in comparative anatomy is that of Carl Gegenbaur (1826-1903), who in arranging the fins of fishes in support of his theory that the fin of the Australian lung-fish (Ceratodus) was the most primitive (or Archipterygium), placed as the primordial type a fin which palaeontology has proved to be one of the latest types if not the last. It is equally true that palaeontological evidence has frequently failed where we most sorely needed it. The student must therefore resort to what may be called a tripod of evidence, derived from the available facts of embryology, comparative anatomy and palaeontology.

**VI.**—**THE PALAEOLOGIST AS HISTORIAN**

The modes of change among animals, and methods of analysing them. As historian the palaeontologist always has before him as one of his most fascinating problems phylogeny, or the restoration of the great tree of animal descent. Were the geologic record complete he would be able to trace the ancestry of man and of all other animals back to their very beginnings...
in the primordial protoplasm. Dealing with interrupted evidence, however, it becomes necessary to exercise the closest analysis and synthesis as part of his general art as a restorer.

The most fundamental distinction in analysis is that which must be made between homogeneity, or true hereditary resemblance, and those multiple forms of adaptive resemblance which are variously known as cases of "analogy," "parallelism," "convergence" and "homoplasy." Of these two kinds of genetic and adaptive resemblance, homogeneity is the warp composed of the vertical, hereditary strands, which connect animals with their ancestors and their successors, while analogy is the woof, composed of the horizontal strands which tie animals together by their superficial resemblances. This wide distinction between similarity of descent and similarity of adaptation applies to every organ, to all groups of organs, to animals as a whole, and to all groups of animals. It is the old distinction between homology and analogy on a grand scale.

Analogy, in its power of transforming unlike and unrelated animals or unlike and unrelated parts of animals into likeness, has done such miracles that the inference of kinship is often almost irresistible. During the past century it was and now is the very "will-o' the-wisp" of evolution, always tending to lead the phylogenist astray. It is the first characteristic of analogy that it is superficial. Thus the shark, the ichthyosaurus, and the dolphin (fig. 10) superficially resemble each other, but if the outer form be removed this resemblance proves to be a mere veneer of adaptation, because their internal skeletal parts are as radically different as are their genetic relations, founded on heredity. Analogy also produces equally remarkable internal or skeletal transformations. The ingenuity of nature, however, in adapting animals is not infinite, because the same devices are repeatedly employed by her to accomplish the same adaptive ends whether in fishes, reptiles, birds or mammals; thus she has repeated herself at least twenty-four times in the evolution of long-snouted rapacious swimming types of animals. The grandest application of analogy is that observed in the adaptations of groups of animals evolving on different continents, by which their various divisions tend to mimic those on other continents. Thus the collective fauna of ancient South America mimics the independently evolved collective fauna of North America, the collective fauna of modern Australia mimics the collective fauna of the Lower Eocene of North America. Exactly the same principles have developed on even a vaster scale among the Invertebrata. Among the ammonites of the Jurassic and Cretaceous periods types occur which in their external appearance so closely resemble each other that they could be taken for members of a single series, and not infrequently have been taken for species of the same genus and even for the same species; but their early stages of development and, in fact, their entire individual history prove them to be distinct and not infrequently to belong to widely separated generic series.

Homogeny, in contrast, the "special homolog" of Owen, is the supreme test of kinship or of hereditary relationship, and thus the basis of all sound reasoning in phylogeny. The two joints of the thumb, for example, are homogenous throughout the whole series of the pentadactylate, or 5-fingered animals, from the most primitive amphibian to man.

The conclusion is that the sum of homogenous parts, which may be similar or dissimilar in external form according to their similarity or diversity of function, and the recognition of former similarities of adaptation (see below) are the true bases for the critical determination of kinship and phylogenetic affinity.

Adaptation and the Independent Evolution of Parts.—Step by step there have been established in palaeontology a number of laws relating to the evolution of the parts of animals which closely coincide with similar laws discovered by zoologists. All are contained in the broad generalization that every part of an animal, however minute, has its separate and independent basis in the hereditary substance of the germ cells from which it is derived and may enjoy consequently a separate and independent history. The consequences of this principle when applied to the adaptations of animals bring us to the very antithesis of Cuvier's supposed "law of correlation," for we find that, while the end results of adaptation are such that all parts of an animal conspire to make the whole adaptive, there is no fixed correlation either in the form or rate of development of parts, and that it is therefore impossible for the palaeontologist to predict the anatomy of an unknown animal from one of its parts only, unless the animal happens to belong to a type generally familiar. For example, among the land vertebrates the feet (associated with the structure of the limbs and trunk) may take on one of many lines of adaptation to different media or habitat, either aquatic, terrestrial, arboreal, or aerial; while the teeth (associated with the structure of the skull and jaw) also may take on one of many lines of adaptation to different kinds of food, whether herbivorous, insectivorous or carnivorous. Through this independent adaptation of different parts to their specific ends there have arisen among vertebrates an almost unlimited number of combinations of foot and tooth structure, the possibilities of which are illustrated in the accompanying diagram (see fig. 11; also Plate III., fig. 8). As instances of such combinations, some of the (probably herbivorous) Eocene monkeys with arboreal limbs have teeth so difficult to distinguish from those of the herbivorous ground-living Eocene horses with cursorial limbs that at first in France and also in America they were both classified with the hoofed animals. Again, directly opposed to Cuvier's principle, we have discovered carnivores with hoofs, such as Mesonyx, and herbivores with slough-like claws, such as Chalicothereium. This latter animal is closely related to one which Cuvier termed Pangolin gigantesque, and had he restored it according to his "law of correlation," he would have pictured a giant "scaly ant-eater," a type as wide as the poles from the actual form of Chalicothereium, which in body, limbs and teeth is a modified ungulate herbivore, related remotely to the tapirs. In its claws alone does it resemble the giant sloths.

This independence of adaptation applies to every detail of structure; the six cusps of a grinding tooth may all evolve alike, or each may evolve independently and differently. Independent evolution of parts is well shown among invertebrates, where the shell of an ammonite, for example, may change markedly in form without a corresponding change in suture, or vice versa.
Similarly, there is no correlation in the rate of evolution either of adjoining or of separated parts; the middle digit of the foot of the three-toed horse is accelerated in development, while the lateral digits on either side are retarded. Many examples might be cited among invertebrates also.

**Fig. 11.—Diagram demonstrating that there are an indefinite number of combinations of various adaptive types of limbs and feet with various adaptive types of teeth, and that there is no fixed law of correlation between the two series of adaptations.**

All these principles are consistent with Francis Galton’s law of particular: inheritance in heredity, and with the modern doctrine of “unity of characters” held by students of Mendelian phenomena.

**Sudden versus Gradual Evolution of Parts.**—There is a broad and most interesting analogy between the evolution of parts of animals and of groups of animals studied as a whole. Thus we observe persistent organs and persistent types of animals, analogous organs and analogous types of animals, and this analogy applies still further to the riddle and more or less contradictory hypotheses of the sudden as distinguished from the gradual appearance of new parts or organs of animals, and the sudden appearance of new types of animals. The first exponent of the theory of sudden appearance of new parts and new types, to our knowledge, was Geoffroy St Hilaire, who suggested saltatory evolution through the direct action of the environment on development, as explaining the abrupt transitions in the Mesozoic Crocodilia and the origin of the birds from the reptiles.

Waagen’s law of mutation, or the appearance of new parts or organs so gradually that they can be perceived only by following them through successive geologic time stages, appears to be directly contradictory to the saltation principle; it is certainly one of the most firmly established principles of palaeontology, and it constitutes the contribution par excellence of this branch of zoology to the law of evolution, since it is obvious that it could not possibly have been deduced from comparison of living animals but only through the long perspective gained by comparison of animals succeeding each other in time. The essence of Waagen’s law is orthogenesis, or evolution in a definite direction, and, if there does exist an internal hereditary principle controlling such orthogenetic evolution, there does not appear to be any essential contradiction between its gradual operation in the “mutations of Waagen” and its occasional hurried operation in the “mutations of de Vries,” which are by their definition discontinuous or saltatory (Osborn, 1907).

**VII.—MODES OF CHANGE IN ANIMALS AS A WHOLE OR IN GROUPS OF ANIMALS, AND METHODS OF ANALYSING THEM.**

1. **Origin from Primitive or Stem Forms.**—As already observed, the same principles apply to groups of animals as to organs and groups of organs; an organ originates in a primitive and un-specialized stage, a group of animals originates in a primitive or stem form. It was early perceived by Huxley, Cope and many others that Cuvier’s broad belief in a universal progression was erroneous, and there developed two different “persistent primitive types” (Huxley) and “progressive types.” The theoretical existence of primitive or stem forms was clearly perceived by Darwin, but the steps by which the stem form might be restored were first clearly enunciated by Huxley in 1880 (“On the Application of Evolution to the Arrangement of the Vertebrata and more particularly of the Mammalia,” Scient. Mem. iv. 457) namely, by sharp separation of the primary or stem characters from the secondary or adaptive characters in all the known descendants or branches of a theoretical original form. The sum of the primitive characters approximately restores the primitive form; and the gaps in palaeontological evidence are supplied by analysis of the available zoological, embryological and anatomical evidence. Thus Huxley, with true prophetic instinct, found that the sum of primitive characters of all the higher placental mammals points to a stem form of a generalized insectivore type, a prophecy which has been fully confirmed by the latest research. On the other hand, Huxley’s summation of the primitive characters of all the mammals led him to an amphibian stem type, a prophecy which has proved faulty because based on unfounded distinctions and comparisons. More or less independently, Huxley, Kowalevsky and Cope restored the stem ancestor of the hoofed animals, or ungulates, a restoration which has been nearly fulfilled by the discovery, in 1873, of the generalized type *Phenacodus* of northern Wyoming. Similar anticipations and verifications among the invertebrates have been made by Hyatt, Beecher, Jackson and others.

In certain cases the character stem forms actually survive in unspecialized types. Thus the analysis of George Bau of the ancestral form of the lizards, mosasaurs, dinosaurs, crocodiles and phytosaurs led both to the generalized *Palaeochorteria* of the Permian and indirectly to the surviving *Tuatera* lizard of New Zealand.

2. **Adaptations to Alternations of Habitat. Law of Irreversibility of Evolution.**—In the long vicissitudes of time—and procession of continental changes, animals have been subjected to alternations of habitat either through their own migrations or through the “migration of the environment itself,” to employ Van den Broeck’s epigrammatic description of the profound and numerous sudden environmental changes which may take place in a single locality. The treatment of alternations of habitats corresponding to these alternations of habitat are recorded both in paleoentology and anatomy, although often after the obscure analogy of the earlier and later writings of a palimpsest. Huxley in 1880 briefly suggested the arboreal origin, or primordial tree-habitat of all the marsupials, a suggestion abundantly confirmed by the detailed studies of Dollo and of Bensley, according to which we may imagine the marsupials to have passed through (1) a former terrestrial phase, followed by (2) a primary arboreal phase—illustrated in the tree phalangers—followed by (3) a secondary terrestrial phase—illustrated in the kangaroos and wallabies—followed by (4) a secondary arboreal phase—illustrated in the tree kangaroos. Louis Dollo especially has
contributed most brilliant discussions of the theory of alterations of habitat as applied to the interpretation of the anatomy of the mammals, of many kinds of fishes, of such reptiles as the herbivorous dinosaurs of the Upper Cretaceous. He has applied the theory with especial ingenuity to the interpretation of the circular bony plates in the carapace of the aberrant leather-backed sea-turtles (Sphargidae) by prefacing an initial land phase, in which the typical armature of land tortoises was acquired, a first marine or pelagic phase, in which this armature was lost, a third littoral or seashore phase, in which a new polygonal armature was acquired, and a fourth resumed or secondary marine phase, in which this polygonal armature began to degenerate.

Each of these alternate life phases may leave some profound modification, which is partially obscured but seldom wholly lost; thus the tracing of the evidences of former adaptations is of great importance in phylogenetic study.

A very important evolutionary principle is that in such secondary returns to primary phases lost organs and never recovered, but new organs are acquired; hence the force of Dool's dictum that evolution is irreversible from the point of view of structure, while frequently reversible, or recurrent, in point of view of the conditions and environment and adaptation.

3. Adaptive Radiations of Groups, Continental and Local.—Starting with the stem forms the descendants of which have passed through either persistent or changed habitats, we reach the underlying idea of the branching law of Lamarck or the law of divergence of Darwin, and find it perhaps most clearly expressed in the words "adaptive radiation" (Osborn), which convey the idea of radii in many directions. Among extinct Tertiary mammals we can actually trace the giving off of these radii in all directions, for taking advantage of every possibility to secure food, to escape enemies and to reproduce kind; further, among such well-known quadrupeds as the horses, rhinoceroses and titanothere, the modifications involved in these radiations can be clearly traced. Thus the history of continental life presents a picture of contemporaneous radiations in different parts of the world and of a succession of radiations in the same part. We observe the contemporaneous and largely independent radiations of the hoofed animals in South America, in Africa and in the great ancient continent comprising Europe, Asia and North America; we observe the Cretaceous radiation of hoofed animals in the northern hemisphere, followed by a second radiation of hoofed animals in the same region, in some cases one surviving spur of an old radiation becoming the centre of a new one. As a rule, the larger the geographic theatre the grander the radiation. Successive discoveries have revealed certain grand centres, such as (1) the marsupial radiation of Australia, (2) the little-known Cretaceous radiation of placental mammals in the northern hemisphere, which was probably connected in part with the peopling of South America, (3) the Tertiary placental radiation in the northern hemisphere, partly connected with Africa, (4) the main Tertiary radiation in South America. Each of these radiations produced a greater or lesser number of analogous groups, and while these initially may be recognized as approaching or related, in most cases, as the evolution proceeds, the original similarity is lost, and the resulting different types are then connected as migrant or invading types. We are thus working out gradually the separate contributions of the land masses of North America, South America, Europe, Asia, Africa, and of Australia to the mammalian fauna of the world, a result which can be obtained through palaeontology only.

4. Adaptive Local Radiation.—On a smaller scale are the local adaptive radiations which occur through segregation of habitat and local isolation in the same general geographic region wherever physiographic and climatic differences are sufficient to produce local differences in food supply or other local factors of change. This local divergence may proceed as rapidly as through wide geographical segregation or isolation. This principle has been demonstrated recently among Tertiary rhinoceroses and titanothere, in which remains of four or five genetic series in the same geologic deposits have been discovered. We have proof that in the Upper Miocene of Colorado there existed a forest-living horse, or more persistent primitive type, which was contemporaneous with and is found in the same deposits with the plains-living horse (Neohippus) of the most advanced or specialized desert type (see Plate IV., figs. 12, 13, 14, 15). In times of drought these animals undoubtedly resorted to the same water-courses for drink, and thus their fossilized remains are found associated.

5. The Law of Polyphyletic Evolution. The Sequence of Phyla or Genetic Series.—There results from continental and local adaptive radiations the presence in the same geographical region of numerous distinct lines in a given group of animals. The polyphyletic law was early demonstrated among invertebrates by Neumayr (1886) when he showed that the ammonite genus Phylloceras follows not one but five distinct lines of evolution of unequal duration. The brachiopods, generally classed collectively as Spirifer muraconotus, follow at least five distinct lines of evolution in the Middle Devonian of North America, while more than twenty divergent lines have been observed by Grabau among the species of the gastropod genus Pusio in Tertiary and recent times. Vertebrate palaeontologists were slow to grasp this principle; while the early speculative phylogenies of the horse of Huxley and Marsh, for example, were mostly displayed monophyletically, or in single lines of descent, it is now recognized that the horses which were placed by Marsh in a single series are really to be ranged in a great number of contemporaneous but separate series, each but partially known, and that the direct phylum which leads to the modern horse has become a matter of far more difficult search. As early as 1862 Gaudry set forth this very polyphyletic principle in his tabular phylogenies, but failed to carry it to its logical application. It is now applied throughout the Vertebrata of both Mesozoic and Cenozoic times. Among marine Mesoic reptiles, each of the groups broadly known as ichthyosaurs, plesiosaurs, mosasaurs and crocodiles were polyphyletic in a marked degree. Among land animals striking illustrations of this local polyphyletic law are found in the existence of seven or eight contemporary series of rhinoceroses, five or six contemporary series of horses, and an equally numerous contemporary series of American Miocene and Pliocene camels; in short, the polyphyletic condition is the rule rather than the exception. It is displayed day-by-day in the antelopes and to a limited degree among the zebras and rhinoceroses of Africa, a continent which exhibits a survival of the Miocene and Pliocene conditions of the northern hemisphere.

6. Development of Analogous Progressive and Retrogressive Groups.—Because of the repetition of analogous physiographic and climatic conditions in regions widely separated both in time and in space, we discover that continental and local adaptive radiations result in the creation of analogous groups of radii among all the vertebrates and invertebrates. Illustrations of this law were set forth by Cope as early as 1861 (see "Origin of Genera," reprinted in the Origin of the Fittest, pp. 95-160) in pointing out the extraordinary parallelisms between unrelated groups of amphibians, reptiles, and mammals. In the Jurassic period there were known more than six different species of reptiles which independently abandoned terrestrial life and acquired more or less perfect adaptation to sea life. Nature, limited in her resources for adaptation, fashioned so many of these animals in like form that we have learned only recently to distinguish similarities of analogous habit from the simulacra of real kinship. From whatever order of Mammalia or Reptilia an animal may be derived, prolonged aquatic adaptation will model its outer, and finally its inner, structure according to certain advantageous designs. The requirements of an elongate body moving through the resistant medium of water are met by the evolution of similar entrant and exit curves, and the bodies of many swiftly moving aquatic animals evolve into forms resembling the hulls of modern sailing yachts (Bashford Dean). We owe especially to Willy Kükenthal, Eberhard Fraas, S. W. Williston and R. C. Osburn a summary of those modifications of form to which aquatic life invariably leads.

The law of analogy also operates in retrogression. A. Smith Woodward has observed that the decline of many groups of
fishes is heralded by the tendency to assume elongate and finally
eel-shaped forms, as seen independently, for example, among
the declining Acanthodians or palaeozoic sharks, among
the modern crossopterygian Polypterus and Calamoichthys of the Nile,
in the modern dipnoean Lepidosiren and Protopterus, in the
Triassic chondrostean Belonorhynchus, as well as in the bow-fin
(Amys) and the garpike (Lepidosiren).

Among invertebrates similar analogous groups also develop.
This is especially marked in retrogressive, though also well-
known in progressive series. The loss of the power to coil,
obtained in the terminals of many declining series of gastropods
from the Cambrian to the present time, and the similar loss of
power among Natiloeida and Ammonoidea of many genetic
series, as well as the ostraean form assumed by various declining
series of pelecypods and by some brachiopods, may be cited as
examples.

7. Periods of Gradual Evolution of Groups.—It is certainly a
very striking fact that wherever we have been able to trace
generic series, either of invertebrates or vertebrates, in closely
sequent geological horizons, or life zones, we find strong proof
of evolution through extremely gradual mutation simultaneously
affecting many parts of each organism, as set forth above. This
proof has been reached quite independently by a very large
number of observers studying a still greater variety of animais.
Such diverse organisms as brachiopods, ammonites, horses and
rhinoceroses absolutely conform to this law in all those rare
localities where we have been able to observe closely sequent
stages. The inference is almost irresistible that the law of gradual
transformation through minute continual change is by far the
most universal; but many palaeontologists as well as zoologists
and botanists hold a contrary opinion.

8. Periods of Rapid Evolution of Groups.—The above law of
gradual evolution is perfectly consistent with a second principle,
namely, that at certain times evolution is much more rapid
than at others, and that organisms are accelerated or retarded in
development, in a manner broadly analogous to the acceleration
or retardation of separate organs. Thus H. S. Williams observes
(\textit{Geological Biology}, p. 268) that the evolution of those funda-
mental characters which mark differences between separate
classes, orders, sub-orders, and even families of organisms, took
place in relatively short periods of time. Among the brachiopods
the chief expansion of each type is at a relatively early period in
their life-history. Hyatt (1883) observed of the ammonites that
each group originated suddenly and spread out with great rapidity.
Déperet notes that the genus \\textit{Nummysa}, an ammonite of the
Kimmeridgian, suddenly branches out into an "explosion"
of forms. Déperet also observes the contrast between periods of
quiescence and limited variability and periods of sudden
efflorescence. A. Smith Woodward ("\textit{Relations of Palaeontology
to Biology}", \textit{Annals and Mag. Natural Hist.}, 1906, p. 317) notes
that the fundamental advances in the growth of fish life have
always been sudden, beginning with excessive vigour at the end of
long periods of apparent stagnation or acquired tardiness, and
are followed by the fixed and definite acquisition of a few new
anatomical character or "expression point," a term first used by
Cope. One of the causes of these sudden advances is un-
doubtedly to be found in the acquisition of a new and extremely
useful character. Thus the perfect jaw and the perfect pair of
lateral fins when first acquired among the fishes favoured a very
rapid and for a time unchecked development. It by no means
follows, however, from this incontrovertible evidence that the
acquisition either of the jaw or of the lateral fins had not in itself
an extremely gradual process.

Thus both invertebrate and vertebrate palaeontologists have
reached independently the conclusion that the evolution of
groups is not continuously at a uniform rate, but that there are,
especially in the beginnings of new phyla or at the time of
acquisition of new organs, sudden variations in the rate of evolu-
tion which have been termed variously "rhythmic," "pulsating,
"efflorescent," "intermittent" and even "explosive" (Déperet).

This varying rate of evolution has (illogically, we believe) been
compared with and advanced in support of the "mutation law
of De Vries," or the theory of saltatory evolution, which we may
next consider.

9. Hypothesis of the Sudden Appearance of New Parts or
Organs.—The rarity of really continuous series has naturally
led palaeontologists to support the hypothesis of brusque transi-
tions of structure. As we have seen, this hypothesis was
fathered by Geoffroy St Hilaire in 1830 from his studies of Mesoz-
ocic Crocodilia, was sustained by Haldemann, and quite recently
has been revived by such eminent palaeontologists as Louis
Dollo and A. Smith Woodward. The evidence for it is not to be
confused with that for the law of rapid efflorescence of groups
just considered. It should be remembered that palaeontology is
the most unfavourable field of all for observation and demon-
stration of sudden saltations or mutations of character, because
of the limited materials available for comparison and the rarity
of genetic series. It should be borne in mind, first, that wherever
a new animal suddenly appears or a new character suddenly
arises in a fossil horizon we must consider whether such appear-
ances may be due to the non-discovery of transitional links with
older forms, or to the sudden invasion of a new type or new organ
which has gradually evolved elsewhere. The rapid variation of
certain groups of animals or the acceleration of certain organs is
also not evidence of the sudden appearance of new adaptive
characters. Such sudden appearances may be demonstrated
possibly in zoology and embryology but never can be demon-
strated by palaeontology, because of the incompleteness of the
geological record.

10. Decline or Senesence of Groups.—Periods of gradual
evolution and of efflorescence may be followed by stationary or
senescent conditions. In his history of the \textit{Arietidae} Hyatt
points out that toward the close of the Cretaceous this entire
group of ammonites appears to have been affected with some
malady; the unrolled forms multiply, the septa are simplified,
the ornamentation becomes heavy, thick, and finally disappears
in the adult; the entire group ends by dying out and leaving no
descendants. This is not due to environmental conditions
solely, because senescent branches of normal progressive groups
are found in all geologic horizons, beginning, for gastropods, in
the Lower Cambrian. Among the ammonites the loss of power
to coil the shell is one feature of racial old age, and in others old
age is accompanied by closer coiling and loss of surface orna-
tmentation, such as spines, ribs, spirals; while in other forms an
arresting of variability precedes extinction. Thūs Williams has
observed that if we find a species breeding perfectly true we can
conceive it to have reached the end of its racial life period.
Brocchi and Daniel Ross (1899) have developed the hypothesis
of the progressive reduction of variability. Such decline is by no
means a universal law of life, however, because among many of
the continental vertebrates at least we observe extinctions
repeatedly occurring during the expression of maximum vari-
ability. Whereas among many ammonites and gastropods smooth
ness of the shell, following upon an ornamental youthful condi-
tion is generally a symptom of decline, among many other
invertebrates and vertebrates, as C. E. Beecher (1876-1909) has
pointed out (1898), many animals possessing hitherto pointed
ward toward the close of their racial history to produce a superfluity
of dead matter, which accumulates in the form of spines among
invertebrates, and of horns among the land vertebrates, reaching
a maximum when the animals are really on the down-grade of
development.

11. The Extinction of Groups.—We have seen that different
lines vary in vitality and in longevity, that from the earliest
times senescent branches are given off, that different lines vary
in the rate of evolution, that extinction is often heralded by
symptoms of racial old age, which, however, vary widely in
different groups. In general we find an analogy between
the development of groups and of organs; we discover that each
phyletic branch of certain organisms traverses a geologic career
comparable to the life of an individual, that we may often
distinguish, especially among invertebrates, a phase of youth, a
phase of maturity, a phase of senility or degeneration fo-

shadowing the extinction of a type.
PALAEOSPONDYLUS

591

Internal causes of extinction are to be found in exaggeration of body size, in the hypertrophy or over-specialization of certain organs, in the irreversibility of evolution, and possibly, although this has not been demonstrated, in a progressive reduction of variability. In a full analysis of this problem of internal and external causes in relation to the Tertiary Mammalia, H. F. Osborn ("Causes of Extinction of the Mammalia," Amer. Naturalist, 1906, pp. 759-759, 829-839) finds that foremost in the long series of causes which lead to extinction are the greater environmental changes, such as physiographic changes, diminished or contracted land areas, substitution of insular for continental conditions; changes of climate and secular lowering of temperature accompanied by deforestation and checking of the food supply; changes influencing the mating period as well as fertility; changes causing increased humidity, which in turn favours enemies among insect life. Similarly secular elevations of temperature, either accompanied by moisture or desiccation, by increasing droughts or by disturbance of the balance of nature, have been followed by great waves of extinction of the Mammalia. In the sphere of living environment, the varied evolution of plant life, the latter periods of forestation and deforestation, the introduction of deleterious plants simultaneously with harsh conditions of life and enforced migration, as well as of mechanically dangerous plants, are among the well-ascertained causes of diminution and extinction.

The evolution of insect life in driving animals from feeding ranges and in the spread of disease probably has been a prime cause of extinction. Food competition among mammals, especially intensified on islands, and the introduction of Carnivora constitute another class of causes. Great waves of extinction have followed the long periods of the slow evolution of relatively inadaptive types of tooth and foot structure, as first demonstrated by Waldemar Kowalevsky; thus mammals are repeatedly observed in a cul-de-sac of structure from which there is no escape in an adaptive direction. Among still other causes are great bulk, which proves fatal under certain new conditions; relatively slow breeding; extreme specialization and development of dominant organs, such as horns and tusks, on which for a time selection centres to the detriment of more useful characters. Little proof is afforded among the mammals of extinction through arrested evolution or through the limiting of variation, although such laws undoubtedly exist. One of the chief deductions is that there are special dangers in numerical diminution of herds, which may arise from a chief or original cause and be followed by a conspiracy of other causes which are cumulative in effect. This survey of the phenomena of extinction in one great class of animals certainly establishes the existence of an almost infinite variety of causes, some of which are internal, some external in origin, operating on animals of different kinds.

VIII.—UNDERLYING BIOLOGICAL PRINCIPLES AS THEY APPEAR TO THE PALEONTOLOGIST

It follows from the above brief summary that palaeontology affords a distinct and highly suggestive field of purely biological research; that is, of the causes of evolution underlying the observable modes which we have been discussing. This result of observation is not favourable to the essentially Darwinian view that the adaptive arises out of the fortuitous by selection, but is rather favourable to the hypothesis of the existence of some quite unknown intrinsic law of life which we are at present totally unable to comprehend or even conceive. We have shown that the direct observation of the origin of new characters in palaeontology brings them within that domain of natural law and order to which the evolution of the physical universe conforms.

The nature of this law, which, upon the whole, appears to be purposive or teleological in its operations, is altogether a mystery which may or may not be illumined by future research. In other words, the origin, or first appearance of new characters, which is the essence of evolution, is an orderly process so far as the vertebrate and invertebrate palaeontologist observes it. The selection of organisms through the crucial test of fitness and the shaping of the organic world is an orderly process when contemplated on a grand scale, but of another kind; here the test of fitness is supreme. The only inkling of possibly underlying principles in this orderly process is that there appears to be in respect to certain characters a potentiality or a predisposition through hereditary kinship to evolve in certain definite directions.

Yet there is strong evidence against the existence of any law in the balance appears to be always sustained between the internal (hereditary and ontogenetic) and the external (environmental and selectional) factors of evolution.

BIBLIOGRAPHY.—Among the older works on the history of palaeontology are the treatises of Giovanni Battista Brocchi (1772—1842) on Palaeontology, Alfred de Quatrefages (1796—1867), Charles Lyell in his Principles of Geology. A clear narrative of the work of many of the earlier contributors is found in Founders of Geology, by Sir Archibald Geikie (London, 1897—1905). The most comprehensive and up-to-date reference work on the history of geology and palaeontology is Geschichte der Geologie by J. Kowalevsky; this was first published in Munich and Leipzig (1899), the final life-work of this great authority, translated into English in part by Maria M. Ogilvie-Gordon, entitled "History of Geology and Palaeontology to the end of the 19th Century." The succession of Quatrefages from the earliest times as it was known to the close of the last century was treated by the same author in his Handbuch der Paläontologie (5 vols., Munich and Leipzig, 1876—1893). Abbreviated editions of this work have appeared from the author, Grundzüge der Paläontologie (Palaeozoologie) (Munich and Leipzig, 1895, 2nd ed., 1903), and in English form in Charles R. Eastman's Text-Book of Palaeontology (1900—1902). A classic but unfinished work describing the methods of invertebrate palaeontology is Die Stömme des Thierreichs (Vienna, 1889), by Melchior Neumayr. In France remarkable recent works are Éléments de Paléontologie, by Félix Bernard (Paris, 1895), and the still more recent philosophical treatise by Charles Depéret, Les Transformations du monde animal (Paris, 1907). Huxley's researches, and especially his share in the development of the methods of palaeontology in its methods of invertebrate palaeontology has been summarized in his essays, The Scientific Memoirs of Thomas Henry Huxley (4 vols., London, 1899—1902). The whole subject is treated systematically in Nicholson and Lydekker's A Manual of Palaeontology (2 vols., London, 1899—1907) and in Woodward's Outline of Vertebrate Palaeontology (Cambridge, 1898).

Among American contributions to vertebrate palaeontology, the development of Cope's theories is to be found in the volumes of his Evidences of Natural Laws (New York, 1868—1879), and the Primary Factors of Organic Evolution (Chicago, 1896). A brief summary of the rise of vertebrate palaeontology is found in the address of O. Marsh, entitled "History and Methods of Palaeontological Discovery" (American Association for the Advancement of Science, 1879). The chief presentations of the methods of the American school of invertebrate palaeontologists are to be found in A. Hyatt's great memoir "Genesis of the Arthrodia" (Smithsonian Institution, 1871), and C. S. Dall's "Patterns as Acquired Characteristic" (Philosophical Soc. Proc., vol. xxxii., 1894), and in Geological Biology, by H. S. Williams (New York, 1895). In preparing the present article the author has drawn freely on his own addresses: see F. Osborn, "The Rise of the Vertebrates in North America" (Proc. Amer. Assn. Adv. Science, vol. xlii., 1893), "Ten Years' Progress in the Mammalian Palaeontology of North America" (Comptes rendus du 6e Congrès intern. de zoologie, session de Bern, 1904), "The Present Problems of Palaeontology" (Address before Section A of the International Congress of Arts and Science, St. Louis, Sept. 1904), "The Causes of Extinction of Mammalia" (Amer. Naturalist, xli., 779-795, 829—859, 1906).

(H. F. O.)

PALAEOSPONDYLUS, a small fish-like organism, of which the skeleton is found fossil in the Middle Old Red Sandstone of Achanerra, near Thursto, Caithness. It was thus named (Gr. ancient vertebra) by Dr R. H. Traquair in 1890, in allusion to its well-developed vertebral rings; and its structure was
studied in detail in 1903 by Professor and Miss Sollas, who succeeded in making enlarged models of the fossil in wax. The skeleton as preserved is carbonized, and indicates an eel-shaped animal from 3 to 5 cm., in length. The skull, which must have consisted of hardened cartilage, exhibits pairs of nasal and auditory capsules, with a gill-apparatus below its hinder part, but no indications of ordinary jaws. The anterior opening of the brain-case is surrounded by a ring of hard cirri. A pair of "post-branchial plates" projects backwards from the head. The vertebral axis shows a series of broad rings, with distinct neural arches, but no ribs. Towards the end of the body both neural and haemal arches are continued into forked radial cartilages, which support a median fin. There are no traces either of paired fins or of dermal armour. The affinities of *Palaeocondylus* are doubtful, but it is probably related to the contemporaneous armoured Ostracoderms.

**PALAEOTHERIUM** (i.e. ancient animal), a name applied by Cuvier to the remains of ungulate mammals calling tapirs in general appearance, from the Lower Oligocene gypsum quarries of Paris. These were the first indications of the occurrence in the fossil state of perissodactyls ungulates allied to the horse, although it was long before the relationship was recognized. The palaeotheres, which range in size from that of a pig to that of a small rhinoceros, are now regarded as representing a family, *Palaeotheriidae*, nearly related to the horse-tribe, and having, in fact, probably originated from the same ancestral stock, namely, *Hyracotherium* of the Lower Eocene (see Equidae). The connecting link with *Hyracotherium* was formed by *Pachynolophus* (Propalaeotherium), and the line apparently terminated in *Palaeotherium*, which is also Oligocene. Representatives of the family occur in many parts of Europe, but the typical genus is unknown in North America, where, however, other forms occur.

Although palaeotheres resemble tapirs in general appearance, they differ in having only three toes on the fore as well as on the hind foot. The dentition normally comprises the typical series of 44 teeth, although in some instances the first premolar is wanting. The cheek-teeth are short-crowned, generally with no cement, the upper molars having a W-shaped outer wall, from which proceed two oblique transverse crests, while the lower ones carry two crescents. Unlike the early horses, the later premolars are as complex as the molars; and although there is a well-marked gap between the canine and the premolars, there is only a very short one between the former and the incisors. The orbit is completely open behind. In other respects the palaeotheres resemble the ancestral horses. They were, however, essentially marsh-dwelling animals, and exhibit no tendency to the cursorial type of limb so characteristic of the horse-line. They were, in fact, essentially inadaptive creatures, and hence rapidly died out. (R.I.)

**PALAEOZOIC ERA,** in geology, the oldest of the great time divisions in which organic remains have left any clear record. The three broad divisions—Palaeozoic, Mesozoic, Cainozoic—

which are employed by geologists to mark three stages in the development of life on the earth, are based primarily upon the fossil contents of the strata which, at one point or another, have been continuously forming since the very earliest times. The precise line in the "record of the rocks" where the chronicle of the Palaeozoic era closes and that of the Mesozoic era opens—as in more recent historical documents—is a matter for editorial caprice. The early geologists took the most natural dividing lines that came within their knowledge, namely, the line of change in general petrological characters, e.g. the "Transition Series" (Übergangsgebirge), the name given to rocks approximately of Palaeozoic age by A. G. Werner because they exhibited a transitional stage between the older crystalline rocks and the younger non-crystalline; later in Germany these same rocks were said to have been formed in the "Kohlenperiode" by H. G. Brunn and others, while in England H. T. de la Beche classed them as a Carbonaceous and Greywacke group. Finally, the divisional time separating the Palaeozoic record from that of the Mesozoic was made to coincide with a great natural break or unconformity of the strata. This was the most obvious course, for where such a break occurred there would be the most marked differences between the fossils found below and those found above the physical discordance. The divisions in the fossil record having been thus established, they must for convenience remain, but their artificiality cannot be too strongly emphasized, for the broad stratigraphical gaps and lithological groups which made the divisions sharp and clear to the earlier geologists are proved to be absent in other regions, and fossils which were formerly deemed characteristic of the Palaeozoic era are found in some places to congregate with forms of strongly marked Mesozoic type. In short, the record is more nearly complete than was originally supposed.

The Palaeozoic or Primary era is divided into the following periods or epochs: Cambrian, Ordovician, Silurian, Devonian, Carboniferous, and Permian. The fact that the rocks of the three earlier epochs—Cambrian, Ordovician, Silurian—have features in common, as distinguished from those in the three later epochs has led certain authors to divide this era into an earlier, Protozoic (Protozoico) and a later Deuterozoic time. The rocks of Palaeozoic age are mainly sandy and muddy sediments with a considerable development of limestone in places. These sediments have been altered to shales, slates, quartizes, &c., and frequently they are found in a highly metamorphosed condition; in eastern North America, however, and in north-east Europe they still maintain their horizontality and primitive texture over large areas. The fossils of the earlier Palaeozoic rocks are characterized by the abundance of trilobites, graptolites, brachiopods, and the absence of all vertebrates except in the upper strata; the later rocks of the era are distinguished by the absence of graptolites, the gradual failing of the trilobites, the continued predominance of brachiopods and the abundance of crinoids and the rapid development of placoderm and heterocercal ganoid fishes and amphibians. The land plants were all cryptogams, *Lepidodendron*, *Sigillaria*, followed by Conifers and Cycads. It is obvious from the advanced stage of development of the organisms found in the earliest of these Palaeozoic rocks that the beginnings of life must go much farther back, and indeed organic remains have been found in rocks older than the Cambrian; for convenience, therefore, the base of the Cambrian is usually placed at the zone of the trilobite *Olenellus*. (J.A. P.)

**PALAEPHATUS,** the author of a small extant treatise, entitled *Pepl Ανίσωσα* (On "Incredible Things"). It consists of a series of rationalizing explanations of Greek legends, without any attempt at arrangement or plan, and is probably an epiteome, composed in the Byzantine age, of some larger work, perhaps the Άριστος των μικρων επιθέματων, mentioned by Suidas as the work of a grammarian of Egypt or Athens. Suidas himself ascribes a *Pepl Ανίσωσα*, in five books, to Palaeaphatus of Paros or Priene. The author was perhaps a contemporary of Euhemerus (3rd century B.C.). Suidas mentions two other writers of the name: (1) an epic poet of Athens, who lived before the time of
Homer; (2) an historian of Abydus, an intimate friend of Aristotle.

See edition by N. Festa, in Mythographi græci (1902), in the Teubner series, with valuable prolegomena supplementary to Intorno all’opuscolo di Palafox de incredibilitis (1899), by the same writer.

Palaestra (Gr. παλαέστρα), the name apparently applied by the Greeks to two kinds of places used for gymnastic and athletic exercises. In the one case it seems confined to the places where boys and youths received a general gymnastic training, in the other to a part of a gymnasium where the athletes, the competitors in the public games, were trained in wrestling (palaiev, to wrestle) and boxing. The boys' palaestrae were private institutions and generally bore the name of the manager or of the founder; thus at Athens there was a palaestra of Tauruces (Plato, Charmides). The Romans used the term gymnasion and palaestra indiscriminately for any place where gymnastic exercises were carried on.

Palafox de Mendoza, Juan de (1600-1659), Spanish bishop, was born in Aragon. He was appointed in 1630 bishop of Angelopolis (Puebla de los Ángeles) in Mexico, and there honourably distinguished himself by his efforts to protect the natives from Spanish cruelty, forbidding any methods of conversion other than persuasion. In this he met with the uncompromising hostility of the Jesuits, whom in 1647 he laid under an interdict. He twice, in 1647 and 1649, laid a formal complaint against them at Rome. The pope, however, refused to approve his censures, and all he could obtain was a brief from Innocent X. (May 14, 1648), commanding the Jesuits to respect the episcopal jurisdiction. In 1653 the Jesuits succeeded in securing his translation to the little see of Osma in Old Castile. In 1664 Charles II. of Spain petitioned for his canonization; but though this passed through the preliminary stages, securing for Palafox the title of "Venerable," it was ultimately defeated, under Pius VI., by the intervention of the Jesuits.

See Antonio González de Resende, Vie de Palafox (French trans., Paris, 1690).

Palafox y Melzi, Joseph de (1780-1847), duke of Saragossa, was the youngest son of an old Aragonese family. Brought up at the Spanish court, he entered the guards at an early age, and in 1800 as a sub-lieutenant accompanied Ferdinand to Bayonne; but after vainly attempting, in company with others, to secure Ferdinand's escape, he fled to Spain, and after a short period of retirement placed himself at the head of the patriot movement in Aragon. He was proclaimed by the populace governor of Saragossa and captain-general of Aragon (May 25, 1808). Despite the want of money and of regular troops, he lost no time in declaring war against the French, who had already overrun the neighbouring provinces of Catalonia and Navarre, and soon afterwards the attack he had provoked began. Saragossa as a fortress was both antiquated in design and scantily provided with munitions and supplies, and the defences resisted but a short time. But it was at that point that the real resistance began. A week's street fighting made the assailants masters of half the town, but Palafox's brother succeeded in forcing a passage into the city with 3000 troops. Stimulated by the appeals of Palafox and of the fierce and rude citizens who ruled the mob, the besieged resolved to continue possession of the remaining quarters of Saragossa inch by inch, and if necessary to retire to the suburb across the Ebro, destroying the bridge. The struggle, which was prolonged for nine days longer, resulted in the withdrawal of the French (Aug. 14), after a siege which had lasted 61 days in all. Palafox then attempted a short campaign in the open country, but when Napoleon's own army entered Spain, and destroyed one hostile army after another in a few weeks, Palafox was forced back into Saragossa, where he sustained a still more memorable second siege. This ended, after three months, in the fall of the town, or rather the cessation of resistance, for the town was in ruins and a pestilence had swept away many thousands of the defenders. Palafox himself, suffering from the epidemic, fell into the hands of the French and was kept prisoner at Vincennes until December 1813. In June 1814 he was confirmed in the office of captain-general of Aragon, but shortly afterwards, it seems, he was released to take part in public affairs. From 1820 to 1823 he commanded the royal guard of King Ferdinand, but, taking the side of the Constitution in the civil troubles which followed, he was stripped of all his honours and offices by the king, whose restoration by French bayonets was the triumph of reaction and absolutism. Palafox remained in retirement for many years. He received the title of duke of Saragossa from Queen Maria Christine. From 1836 he took part in military and political affairs as captain-general of Aragon and a senator. He died at Madrid on the 15th of February 1847.

A biographical notice of Palafox appeared in the Spanish translation of Thierry's Hist. des consulates de l'empire, by P. de Madrgo. For the life of Palafox, see Vida Palafox de Melquiades y Castiglione, by Antonio de Calima, 1763; and the work by Palafox himself, Vida de Palafox, by Philippo, 1836, and the anecdotal Resumen of him by Nicola Palafox, 1847. Palafox was also the author of a poem on the War, vol. 1; this account is both more accurate and more just than Napier's.

Palamas, Gregorius (c. 1266-1339), Greek mystic and chief apologist of the Hesychasts (q.v.), belonged to a distinguished Anatolian family, and his father held an important position at Constantinople. Palamas at an early age retired to Mt Athos, where he became acquainted with the mystical theories of the Hesychasts. In 1326 he went to Skètè near Beroea, where he spent some years in isolation in a cell specially built for him. His health having broken down, he returned to Mt Athos, but, finding little relief, removed to Thessalonica. About this time Barlaam, the Calabrian monk, began his attacks upon the monks of Athos, and Palamas came to be their champion. In 1341 and 1345 he took part in the two synods at Constantinople, which definitely secured the victory of the Palamites. During the civil war between John Cantacuzene and the Palaeologoi, Palamas was imprisoned. After Cantacuzene's victory in 1347, Palamas was released and appointed archbishop of Thessalonica; being refused admittance by the inhabitants, he retired to the island of Lemnos, but subsequently obtained his see. Palamas endeavoured to justify the mysticism of the Hesychasts on dogmatic grounds. The chief objects of his attack were Barlaam, Gregorius Acindynus and Nicephorus Gregorius.

Palamas was a prolific writer, but only a few of his works have been published, most of which will be found in J. P. Migne, Patrologia Graecae (Paris, 1857-1866, 145 vols.), containing the ascensions, and their doctrine of the Procession of the Holy Ghost; Hesychastic writings; homilies; a life of St Peter (a monk of Athos); a rhetorical essay Prosopopeia (ed. A. Jahn, 1884), containing the accusations brought against the body by the soul, the defence made by the body, and the final pronounce of the judges in favour of the body, on the ground that its sins are the result of inadequate teaching.

See the historical works of John Cantacuzene and Nicephorus Gregorius; likewise the Vita Palamae by Phillotus, and the encomium by Nius (both patriarchs of Constantinople); also C. Krumbacher, Geschichte der byzantinischen Literatur (1897).

Palamau, a district of British India, in the Chota-Nagpur division of Bengal. It was formed out of Lohardaga, in 1849, and takes its name from a former state or chiefship. The administrative headquarters are at Daltonganj; pop. (1901), 5837. It consists of the lower spurs of the Chota-Nagpur plateau, sloping north to the valley of the Son. Area 4914 sq. m.; pop. (1901), 619,600, showing an increase of 3-8% in 15 years. Agriculture consists of jute and sugarcane; 126 persons per sq. m., being the lowest in all Bengal. Palamu suffered severely from drought in 1897. A branch of the East Indian railway from the Son valley to the valuable coalfield near Daltonganj was opened in 1902. The only articles of export are jungle produce, such as lac and tussur silk. The forests are unprofitable.

See Palamu District Gazetteer (Calcutta, 1897).

Palamcottah, a town of British India, in the Tinnevelly district of Madras, on the opposite bank of the Tambraparni river to Tinnevely town, with which it shares a station on the South Indian railway, 444 m. south of Madras. Pop. (1901), 39,545. It is the administrative headquarters of the district, and also the chief centre of Christian missions in south India. Among many educational institutions may be mentioned the Sarah Tucker College for Women, founded in 1895.
PALAMEDES, in Greek legend, son of Nauplius king of Euboea, one of the heroes of the Trojan War, belonging to the post-Homeric cycle of legends. During the siege of Troy, Ajax's menon, Diomedes and Odysseus (who had been detected by Palamedes in an attempt to escape going to Troy by shaming madness) caused a letter containing money and purporting to come from Priam to be concealed in his tent. They then accused Palamedes of treasonable correspondence with the enemy, and he was ordered to be stoned to death. His father exacted a fearful vengeance from the Greeks on their way home, by placing false lights on the promontory of Capeareus. The story of Palamedes was first handled in the Cypria of Stasinus, and formed the subject of lost plays by Aeschylus (Palamedes), Sophocles (Nauplius), Euripides (Palamedes), of which some fragments remain. Sophists and rhetoricians, such as Gorgias and Alcidamas, amused themselves by writing declamations in favour of or against him. Palamedes was regarded as the inventor of the alphabet, lighthouses, weights and measures, dice, backgammon and the discus.

See Euripides, Orestes, 432 and scholi.; Ovid, Metam., xiii. 56; Serv. on Virgil, Aen. ii. 21, 29, and Nettleship's use of A. in C. G. and J. G.; Philostratus, Heroicus, 11; Euripides, Frag. 581; for different versions of his death see Dictys Cretensis ii. 15; Pausanias ii. 20, 3; x. 31, 2; Dares Phrygius, 28; monograph by O. Jahn (Hamburg, 1896).

PALANPUR, a native state of India, in the Gujarat division of Bombay, on the southern border of Rajputana. Area, 1766 sq. m.; pop. (1901), 223,937, being less than one-fourth of the decrease of population during the decade 1891-1901. It is a mokhatoon, with much forest towards the north, but undulating and open in the south and east. The principal rivers are the Saraswati and Banas. The estimated gross revenue is £30,000; tribute to the gaekwar of Baroda, £25,000. The chief, whose title is diwan, is an Afghan by descent. The state is traversed by the main line of the Rajputana—Malwa railway, and contains the British cantonment of Deesa. Wheat, rice and sugar-cane are the chief products. The state has suffered severely of recent years from plague. The town of Palanpur is a railway junction for Deesa, 18 m. distant. Pop. (1901), 17,799.

Palanpur also gives its name to a political agency, or collection of native states; total area, 6930 sq. m.; pop. (1901), 465,271, showing a decrease of 25% in the decade, due to the effects of famine.

PALAQUIN (pronounced palankeen, a form in which it is sometimes spelled), a covered litter used in India and other Eastern countries. It is usually some eight feet long by four feet in width and depth, fitted with movable blinds or curtains, and slung on four cords carried by four men, with much forest towards the north, but undulating and open in the south and east. The principal rivers are the Saraswati and Banas. The estimated gross revenue is £30,000; tribute to the gaekwar of Baroda, £25,000. The chief, whose title is diwan, is an Afghan by descent. The state is traversed by the main line of the Rajputana—Malwa railway, and contains the British cantonment of Deesa. Wheat, rice and sugar-cane are the chief products. The state has suffered severely from recent years from plague. The town of Palanpur is a railway junction for Deesa, 18 m. distant. Pop. (1901), 17,799.

Palanpur also gives its name to a political agency, or collection of native states; total area, 6930 sq. m.; pop. (1901), 465,271, showing a decrease of 25% in the decade, due to the effects of famine.

PALATE (Lat. palatum, possibly from the root of passare, to feed), the roof of the mouth in man and vertebrate animals. The palate is divided into two parts, the anterior bony "hard palate" (see MOUTH), and the posterior fleshy soft palate (see PHARYNX). There is a longitudinal fissure in the roof of the mouth, see CLEFT PALATE.

PALATinate (Ger. Pfalz), a name given generally to any district ruled by a count palatine, but particularly to a district of Germany, a province of the kingdom of Bavaria, lying west of the Rhine. It is bounded on the N. by the Prussian Rhine province and the Hessian province of Rhein-Hessen; on the E. by Baden, from which it is separated by the Rhine; on the S. by the imperial province of Alsace-Lorraine, from which it is divided by the Lauter and other W. by the administrative districts of Trier and Coblenz, belonging to the Prussian Rhine province. It has an area of 2288 sq. m., and a population (1905) of 885,280, showing a density of 3869 to the square mile. As regards religion, the inhabitants are fairly equally distributed into Roman Catholics and Protestants.

The rivers in this fertile tract of country are the Rhine, Lauter, Queich, Speyrbach, Glan and Bles. The Vosges, and their continuation the Hadri, run through the land from south to north and divide it into the fertile and mild plain of the Rhine, together with the slope of the Hardt range, on the east, and the rather inclement district on the west, which, running between the Saarbrück carboniferous mountains and the northern spurs of the Hardt range, ends in a porphyry cluster of hills, the highest point of which is the Donnersberg (2525 ft.). The country on the east side and on the slopes of the Hardt yield a number of the most varied products, such as wine, fruit, corn, vegetables, flax and tobacco. Cattle are reared in great quantity and are of excellent quality. The mines yield iron, coal, quicksilver and salt. The industries are very active, especially in iron, machinery, paper, chemical, shoes, woolen goods, beer, leather goods, and many other commodities served by railway communication and, for purposes of administration, is divided into the following 16 districts: Bergzabern, Dürkheim, Frankenthal, Germersheim, Homburg, Kaisersauers, Kirchheimbolanden, Kusel, Landau, Ludwigshafen, Neustadt, Pirmasens, Rockenhausen, St. Ingbert, Spires and Zweibrücken. Spires (Speyer) is the seat of government, and the chief industrial centres are Ludwigshafen on the Rhine, which is the principal river port, Landau, and Neustadt, the seat of the wine trade.

See A. Becker, Die Pfalz und die Pfälzer (Leipzig, 1857); Mehls, Fabrikten durch die Pfalz (Augsburg, 1877); P. Schlieben, Handbuch der Pfalz (Spires, 1902); H. Henry, Pfalzgärtner (Neustadt, 1907); and Näher, Die Burgen der rheinischen Pfalz (Strassburg, 1887).

History.—The count palatine of the Rhine was a royal official who is first mentioned in the 10th century. The first count was Hermann I., who ruled from 945 to 996, and although the office was not hereditary it appears to have been held mainly by his descendants until the death of Count Hermann III. in 1155. These counts had gradually extended their powers, had obtained the right of advocacy over the archbishop of Trier and the bishopric of Juliers, and ruled various isolated districts along the Rhine. In 1155 the German king, Frederick I., appointed his brother Conrad as count of the Rhine. Conrad took up his residence at the castle of Burghaubach, near Heidelberg, which became the capital of the Palatinate. In 1195 Conrad was succeeded by his son-in-law Henry, son of Henry the Lion, duke of Saxony, who was a loyal supporter of the emperor Henry VI. After the latter's death in 1197 he assisted his own brother Otto, afterwards the emperor Otto IV., in his attempts to gain the German throne. Otto refused to reward Henry for his support, so in 1204 he assisted his rival, the German king Philip, but returned to Otto's side after Philip's murder in 1208. In 1211 Henry abdicated in favour of his son Henry, who died in 1214, when the Palatinate was given by the German king Frederick II. to Otto, the infant son of Louis I., duke of Bavaria, a member of the Wittelsbach family, who was betrothed to Agnes, sister of the late count, Henry. The break-up of the duchy of Franconia had increased the influence of the count palatine of the Rhine, and the importance of his position among the princes of the empire is shown by Roger of Hoveden, who, writing of the election to the German throne in 1306, singles out four princes as chief electors, among whom is the count palatine of the Rhine. In the Sachsenspiegel, a collection of German laws which was written before 1235, the count is given as the butler (dajifher) of the emperor, the first place among the lay electors.

The Palatinate was ruled by Louis of Bavaria on behalf of his son until 1228, when it passed to Otto who ruled until his death in 1253. Otto's possessions were soon afterwards divided,
and his elder son Louis II. received the Palatinate and Upper Bavaria. Louis died in 1294 when these districts passed to his son Rudolph I. (d. 1319), and subsequently to his grandson Louis, afterwards the emperor Louis IV. By the Treaty of Pavia in 1329, Louis granted the Palatinate to his nephews Rudolph II. and Rupert I., who received from him at the same time a portion of the duchy of Upper Bavaria, which was called the upper Palatinate to distinguish it from the Rhenish, or lower Palatinate. Rudolph died in 1353, after which Rupert ruled alone until his death in 1390. In 1355 he had sold a portion of the upper Palatinate to the emperor Charles IV., but by various purchases he increased the area of the Rhenish Palatinate. His successor was his nephew Rupert II., who bought from the German king Wenceslaus a portion of the territory that his uncle had sold to Charles IV. He died in 1398 and was succeeded by his son Rupert III. In 1400 Rupert was elected German king, and when he died in 1410 his possessions were divided among his four sons: the eldest, Louis III., received the Rhenish Palatinate proper; the second son, John, obtained the upper Palatinate; while the outlying districts of Zweibrücken and Simmern passed to Stephen, and that of Mosbach to Casimir.

When the possessions of the house of Wittelsbach were divided in 1355 and the branches of Bavaria and the Palatinate were founded, a dispute arose over the exercise of the electoral vote, and the question was not settled until in 1356 the Golden Bull bestowed the privilege upon the count palatine of the Rhine, who exercised it until 1623. The part played by Count Frederick V., titular king of Bohemia, during the Thirty Years' War induced the emperor Ferdinand II. to deprive him of his vote and to transfer it to the duke of Bavaria, Maximilian I. By the Peace of Westphalia in 1648 an eighth electorate was created for the count palatine, to which was added the office of treasurer. In 1777, however, the count resumed the ancient position of his family in the electoral college, and regained the office of steward which he retained until the formal dissolution of the empire in 1806.

To return to the history of the Palatinate as divided into four parts among the sons of the German king Rupert in 1410. John, the second of these brothers, died in 1445, and his son, Christian, having become king of Denmark in 1444, did not inherit the upper Palatinate, which was again united with the Rhenish Palatinate. Otto, the son of Otto (d. 1461), Rupert's fourth son, who had obtained Mosbach, died without sons in 1499, and this line became extinct, leaving only the two remaining lines with interests in the Rhenish Palatinate. After Rupert's death this was governed by his eldest son, the elector Louis III. (d. 1436), and then by the latter's sons, Louis IV. (d. 1449) and Frederick I. The elector Frederick, called the Victorious, was one of the foremost princes of his time. His nephew and successor, the elector Philip, carried on a war for the possession of the duchy of Bavaria-Landshut, which had been bequeathed to his son Rupert (d. 1504), but, when in 1507 an end was put to this struggle, Rupert's son, Otto Henry, only received Neuburg and Sulzbach. Louis V. and then Frederick II. succeeded Philip, but both died without sons and Otto Henry became elector of Bavaria. He had however sons in 1559, when the senior branch became extinct, leaving only the branch descended from Rupert's third son, Stephen.

Already on Stephen's death in 1559 this family had been divided into two branches, those of Simmern and of Zweibrücken, and in 1554 the latter branch had been divided into the lines of Zweibrücken proper and of Veldenz. It was Frederick, count palatine of Simmern, who succeeded to the Palatinate on Otto Henry's death, becoming the elector Frederick III. The new elector, a keen but not a very bigoted Calvinist, was one of the most active of the Protestant princes. His son and successor, Louis VI. (d. 1583), was a Lutheran, but another son, John Casimir, who ruled the electorate on behalf of his young nephew, Frederick IV., from 1583 to 1592, gave every encouragement to the Calvinists. A similar line of action was followed by Frederick IV. himself after 1592.

He was the founder and head of the Evangelical Union established to combat the aggressive tendencies of the Roman Catholics. His son, the elector Frederick V., accepted the crown of Bohemia and thus brought on the Thirty Years' War. He was quickly driven from that country, and his own electorate was devastated by the Bavarians and Spaniards. At the peace of Westphalia in 1648 the Palatinate was restored to Frederick's son, Charles Louis, but it was shorn of the upper Palatinate, which Bavaria retained as the prize of war.

Scarcely had the Palatinate begun to recover when it was attacked by Louis XIV. For six years (1672-79) the electorate was devastated by the French troops, and even after the Treaty of Nijmegen it suffered from the aggressive policy of Louis. In August 1680 the elector Charles Louis died, and when his son and successor, Charles, followed him to the grave five years later the ruling family became extinct in the senior line. Mention has already been made of a division of this family into two lines after 1459, and of a further division of the Zweibrücken line in 1514, when again two lines were founded. The junior of these, that of Veldenz, became extinct in 1694, but the senior, that of Zweibrücken proper, was still very strong. The house of Veldenz (d. 1569) had purchased Sulzbach and Neuburg in 1557, and in the person of his grandson, Wolfgang William (d. 1653) it had secured the coveted dukedoms of Juliers and Berg. It was Philip William of Neuburg, the son of Wolfgang William, who became elector palatine in succession to Charles in 1685.

The French king's brother, Philip, duke of Orleans, had married Charlotte Elizabeth, a sister of the late elector Charles, and consequently the French king claimed a part of Charles's lands in 1680. His troops took Heidelberg and devastated the Palatinate, while Philip William took refuge in Vienna, where he died in 1690. Then in 1697, by the Treaty of Ryswick, Louis abandoned his claim in return for a sum of money. Just before this date the Palatinate began to be disturbed by troubles about religion. The great majority of the inhabitants were Protestants, but the family which succeeded in 1685 belonged to the Roman Catholic Church. Philip William, however, gave equal rights to all his subjects, but under his son and successor, the elector John William, the Protestants were deprived of various civil rights until the intervention of Prussia, and of Brunswick in 1705 gave them some redress. The next elector, a brother of the last one, was Charles Philip, who removed his capital from Heidelberg to Mannheim in 1720. He died without male issue in December 1742. His successor was his kinsman, Charles Theodore, count palatine of Sulzbach, a cadet of the Zweibrücken-Neuburg line, and now with the exception of one or two small pieces the whole of the Palatinate was united under one ruler. Charles Theodore was a prince of refined and educated tastes and during his long reign his country enjoyed prosperity. In 1777 on the extinction of the other branch of the house of Wittelsbach, he became elector of Bavaria, and the Palatinate was henceforward united with Bavaria, the elector's capital being Munich. Charles Theodore died without legitimate sons in 1799, and his successor was Maximilian Joseph, a member of the Birkenfeld branch of the Zweibrücken family, who later became king of Bavaria as Maximilian I.

In 1802 the elector was obliged to cede the portion of the Palatinate lying on the left bank of the Rhine to France, and other portions to Baden and to Hesse-Darmstadt. Much of this, however, was regained in 1815, and since that date the Palatinate has formed part of the kingdom of Bavaria.

**PALATINE** (from Lat. *palatum*, a palace), pertaining to the palace and therefore to the emperor, king or other sovereign
ruler. In the later Roman Empire certain officials attending on the emperor, or discharging other duties at his court, were called palatini; from the time of Constantine the Great the term was also applied to the soldiers stationed in the neighborhood of the capital to distinguish them from those stationed on the frontier of the empire. In the East Roman Empire the word was used to designate officials concerned with the administration of the finances and the imperial lands.

This use of the word palatine was adopted by the Frankish kings of the Merovingian dynasty. They employed a high official, the comes palatinus, who at first assisted the king in his judicial duties and at a later date discharged many of these himself. Other counts palatine were employed on military and administrative work, and the system was maintained by the Carolingian sovereigns. The word paladin, used to describe the followers of Charlemagne, is a variant of palatine. A Frankish caputalcity of 882 and Hincmar, archbishop of Reims, writing about the same time, testify to the extent to which the judicial work of the Frankish Empire had passed into their hands, and one grant of power was followed by another. Instead of remaining near the person of the king, some of the counts palatine were sent to various parts of his empire to act as judges and governors, the districts ruled by them being called palatinate. Being in a way the vanguard of the administration, the palatines were entrusted with more extended power than the ordinary counts. Thus comes the later and more general use of the word palatine, its application as an adjective to persons entrusted with special powers and also to the districts over which these powers were exercised. By Henry the Fowler and especially by Otto the Great, they were sent into all parts of the country to support the royal authority by checking the independent tendencies of the great tribal dukes. We hear of a count palatine in Saxony, and of others in Lorraine, in Bavaria and in Swabia, their duties being to administer the royal estates in these duchies. The count palatine in Bavaria, an office held by the family of Wittelsbach, became duke of this land, the lower title being then merged in the higher one; and with one other exception the German counts palatine soon became insignificant, although, the office having become hereditary, Pfalzgrafen were in existence until the dissolution of the Holy Roman Empire in 1606. The exception was the count palatine of the Rhine, who became one of the four lay electors and the most important lay office. The most important of the counties palatine were Durham and Chester, the bishop of the one and the earl of the other receiving special privileges from William I. Chester had its own parliament, consisting of barons of the county, and was not represented in the national assembly until 1541, while it retained some of its special privileges until 1830. The bishop of Durham retained temporal jurisdiction over the county until 1836. Lancashire was made a county, or duchy, palatine in 1531, and kept some of its special judicial privileges until 1873. Thus for several centuries the king's writs did not run in these three palatine counties, and at the present day Lancashire and Durham have their own courts of chancery. Owing to the ambiguous application of the word palatine to Odo, Bishop of Bayeux, it is doubtful whether Kent was ever a palatine county; if so, it was one only for a few years during the 11th century. Other palatine counties, which only retained their exceptional position for a short time, were Shropshire, the Isle of Ely, Hexhamshire in Northumbria, and Pembroke-shire in Wales. In Ireland there were palatine districts, and the seven original earldoms of Scotland occupied some positions somewhat analogous to that of the English palatine counties.

In Hungary the important office of palatine (Magyar Nődor) owes its inception to St Stephen. At first the head of the judicial system, the palatine undertook other duties, and became after the king the most important person in the realm. At one time he was chosen by the king from among four candidates named by the Diet. Under the later Habsburg rulers of Hungary the office was several times held by a member of this family, one of the palatines being the archduke Joseph. The office was abolished after the revolution of 1848.

In Poland the governors of the provinces of the kingdom were called palatines, and the provinces were sometimes called palatinate.

In America certain districts colonized by English settlers were treated as palatine provinces. In 1632 Cecillus Calvert, 2nd Lord Baltimore, received a charter from Charles I, giving him palatine rights in Maryland. In 1639 Sir Ferdinando Gorges, the lord of Maine, obtained one granting him as large and ample prerogatives as were enjoyed by the bishop of Durham. Carolina was another instance of a palatine province.

In addition to the authorities mentioned, see R. Schröder, Lehrbuch der deutschen Rechtsgeschichte (Leipzig, 1902); C. Pfaff, Geschichte des Pfalzgrafenamtes (Halle, 1847); G. T. Lapsley, The County Palatine of Durham (New York, 1900), and D. J. Medley, English Constitutional History (1907). (A. W. H. II.)

**PALATKA, a city and the county-seat of Putnam county, Florida, U.S.A., in the N.E. part of the state, on the W. bank of the St John’s river, about 100 m. from its mouth, and at the head of deep-water navigation. Pop. (1905) 3950; (1910) 3779. Palatka is served by the Georgia Southern & Florida (of which it is the southern terminal), the Atlantic Coast Line, and the Florida East Coast railways, and also has connexion by the New York and Boston. Palatka is situated in a rich agricultural, orange-growing and timber region, for which it is the distributing centre. Large quantities of cypress lumber are shipped from Palatka. Palatka was incorporated as a town in 1853, and in 1872 was chartered as a city.

**PALAVER (an adaptation of Port. palavra, a word or speech; Ital. parola; Fr. parole, from the Low Lat. parabola, a parable, story, talk; Gr. παραβολή, literally “comparison”; the Low Lat. parabolare, “to talk,” gives Fr. parler, “to speak,” whence “parley,” “parliament,” &c.), the name used by the Portuguese traders on the African coast for their conversations and bargaining with the natives. It was introduced into English in the 18th century through English sailors frequenting the Guinea coast. It has now passed into general use among the negroes of West and West Central Africa for any conference, either among themselves or with foreigners. From the amount of unnecessary talk characteristic of such meetings with natives, the word is used of any idle or cajoling talk.

**PALAWARAM, a town of British India, in Chingleput district, *Madras* presid., on the Chingleput river, a station on the South Indian railway; pop. (1901), 4626. Formerly called the presidy cantium, as containing the native garrison for Madras city, it is now a dépôt for native infantry and the residence of European pensioners. There are several taverns.

**PALLAZZOLO ACREIDE, a town of Sicily, in the province of Syracuse, 28 m. by road W. of it, 2285 ft. above sea-level. Pop. (1901), 14,840. The town occupies the site of the ancient Acrae, founded by Syracuse about 664 B.C. It followed in the main the fortunes of the mother city. In the treaty between the Romans and Hiero II. in 263 B.C. it was assigned to the latter. The ancient city lay on the hill above the modern town, the
approach to it being defended by quarries, in which tombs of all periods have been discovered. The auditorium of the small theatre is well preserved, though nothing of the stage remains. Close to it are ruins of other buildings, which, bear, without justification, the names Naumachia, Odeum (perhaps a bath establishment) and Palace of Hiero. The water supply was obtained by subterranean aqueducts. In the cliffs of the Monte Pincio to the south are other tomb chambers, and to the south again are the curious bas-reliefs called Santoni or Sanitelli, mutilated in the 19th century by a peasant proprietor, which appear to be sepulchral also. Near here too is the necropolis of the Acrocero della Torre, where many sarcophagi have been found. Five miles north lies Buscemi, near which a sacred grotto has been discovered; and also a church cut in the rock and surrounded by a cemetery.¹

See G. Judica, Antichità di Acre (Messina, 1819). (Baron Judica’s collection of antiquities was dispersed after his death.) J. Schubring, Jahrbuch für Philologie, Suppl. IV., 636-672.

PALE (through Fr. pal, from Lat. palus, a stake, for palleus, from the stem pag- of pander, to fix; *palle* is from the same original source), a stake, particularly one of a closely set series driven into the ground to make the defensive work known as a *palisade*, also one of the lighter laths or strips of wood set vertically and fastened to a horizontal rail to form a *paling*. Used as an historical term, a pale is a district marked off from the surrounding country by a different system of government and law or by definite boundaries. The best known of these districts was the “English Pale” in Ireland, dating from the reign of Henry II., although the word “pale” was not used in this connexion until the latter part of the 14th century. The Pale varied considerably, according to the strength or weakness of the English authorities, and in the time of Henry VIII. was bounded by a line drawn from Dunlough to Kells, thence to Naas, and from Naas E. to Dalkey, embracing, that is, part of the modern counties of Dublin, Louth, Meath, and Kildare. The Pale existed until the complete subjugation of Ireland under Elizabeth; the use of the word is frequent in Tudor times. There was an “English Pale” or “Calais Pale” also in France until 1558, extending from Gravelines to Wissant, and for a short time under the Tudors an English Pale in Scotland. In heraldry a “pale” is a band placed vertically in the centre of a shield, hence “in pale” or “to impale” is used of the marshalling of two coats side by side on a shield divided vertically.

“Paler,” in the sense of colourless, whitish, of a shade of colour lighter than the normal, is derived through O. Fr. paler, mod. pale, from Lat. pallidus, pallor, pallidus; and in that of a baker’s shovel, or “peel” as it is sometimes called, from Lat. pala, spade, probably connected with the root of pandere, to spread out.

PALEARIO, AONIO (c. 1500-1570), Italian humanist and reformer, was born about 1500 at Veroli, in the Roman Campagna. Other forms of his name are Antonio Della Paglia, A. Degli Pagliaricci. In 1520 he went to Rome, where he entered the brilliant literary circle of Leo X. When Charles of Bourbon consumed Rome in 1527 Paleario went first to Perugia and then to Siena, where he settled as a teacher. In 1536 his didactic poem in Latin hexameters, De immortalitate animarum, was published at Lyons. It is divided into three books, the first containing his proofs of the divine existence, and the remaining two the theological and philosophical arguments for immortality based on that postulate. The whole concludes with a rhetorical description of the occurrences of the Second Advent. In 1542 a tract, written by him and entitled De divina immortalitate, sua sufficientia, et satisfactione della passione di Christo, or Libellus de morte Christi, or De morte Christi, was published. Inquisition the basis of a charge of heresy from which, however, he successfully defended himself. In Siena he wrote his Actio in pontificis romanis et eorum ascensae, a vigorous indictment, in twenty “testimonii,” against what he now believed to be the fundamental error of the Roman Church in substituting Scripture to tradition, as well as against various particular doctrines, such as that of

¹ P. Oros in Notizie degli Scavi (1890), 452-471; Römische Quartalschrift (1898), 624-631.

puratory; it was not, however, printed until after his death (Leipzig, 1605). In 1546 he accepted a professorial chair at Lucca, which he exchanged in 1555 for that of Greek and Latin literature at Milan. Here about 1566 his enemies renewed their activity, and in 1567 he was formally accused by Fra Angelo the inquisitor of Milan. He was tried at Rome, condemned to death in October 1560, and executed in July 1570.

An edition of his works (Ant. Palearii Verulani Opera), including four books of Epistolae and twelve Orationes besides the De immortalitate, was published at Lyons in 1552; this was followed by two, at Basel, and several after his death, the fullest being published in 1606. A work, entitled Beneficio et Cristo ("The Benefit of Christ’s Death"), has been attributed to Paleario on insufficient grounds. Lives by Gurlitt (Hamburg, 1805); Young (2 vols., London, 1860); Bonnet (Paris, 1862).

PALENCIA, an inland province of Spain, one of the eight into which Old Castile was divided in 1583; bounded on the N. by Santander, E. by Burgos, S. by Valladolid, and W. by Valladolid and Leon. Pop. (1900), 592,472; area, 3,256 sq. m. The surface of the province slopes gradually S. to the Duero (Douro) valley. The principal rivers are the Pisueña and the Carrion, which unite at Dueñas and flow into the Duero at Valladolid. The chief tributaries of the Pisueña within the province are the Arlanzón, the Burejo, the Clouza, and the united streams of the Buedo and Abanades; the Carrion is joined on the right by the Cueva. The north is traversed by the Cantabrian Mountains, the highest summit being the culminating point of the Picos del Bremón (6,553 ft.). There are extensive forests in this region and the valleys afford good pastureage. The remainder of Palencia, the “Tierra de Campos,” belongs to the great Castilian table-land. In the south is a marsh or lake, known as La Laguna de la Nava. The mountainous district abounds in minerals, but only coal and small quantities of copper are worked. The province is crossed in the south-east by the trunk railway connecting Madrid with France via Irun, while the line to Santander traverses it throughout from north to south; there are also railways from the city of Palencia to Leon, and across the north from Mataporquera in Santander to La Robla in Leon. A branch of the Santander line gives access to the Ordo coal-fields. The main highways are good; the other roads often bad. The Canal de Castilla, begun in 1753, and completed in 1832, connects Alar del Rey with Valladolid. Wheat and other cereals, vegetables, hemp and flax are extensively grown, except in the mountainous districts. Flour and wine are made in large quantities, and there are manufactures of linen and woolen stuffs, oil, porcelain, leather, paper and rugs. Palencia rugs are in great demand throughout Spain. The only town with more than 5,000 inhabitants is Palencia (g. n.).

For the history, inhabitants, &c., see CASTILE.

PALENCIA, an episcopal city, and the capital of the Spanish province of Palencia; on the left bank of the river Carrion, on the Canal de Castilla, at the junction of railways from Leon and Santander, and 7 m. N. by W. of Venta de Baños on the Madrid-Irun line. Pop. (1900), 15,940. Palencia is built in the midst of the level plains called the Tierra de Campos, 2,690 ft. above sea-level. Three bridges across the Carrion afford access to the modern suburbs on the right bank. The older and by far the more important part of the city is protected on the west by the river; on the other sides the old maccellated walls, 36 ft. high by 9 ft. in thickness, are in fairly good preservation, and beautified by alameda or promenades, which were laid out in 1778. The cathedral was begun in 1321, finished in 1504, and dedicated to St Antolin; it is a large building in the later and florid Gothic style of Spain. The site was previously occupied by a church erected by Sancho III. of Navarre and Castle (1026-1053) over the cave of St Antolin, which is still shown. The cathedral contains some valuable paintings, old Flemish tapestries, and beautiful carved woodwork and stonework. The church of San Miguel is a good and fairly well-preserved example of 13th-century work; that of San Francisco, of the same date, is inferior and has suffered more from modernization. The
hospital of San Lazaro is said to date in part from the time of the Cid (q.v.), who here married Ximena in 1074.

Much has been done for education. Palencia has also hospitals, a foundling refuge, barracks and a bull-ring. Local industries include iron-foundling, and the making of rugs, alcohol, leather, soap, porcelain, linen, cotton, wool, machinery and matches.

Palencia, the Pallantia of Strabo and Ptolemy, was the chief town of the Vaccet. Its history during the Gothic and Moorish periods is obscure; but it was a Castilian town of some importance in the 12th and 13th centuries. The university founded here in 1208 by Alphonso IX. was removed in 1239 to Salamanca.

**PALENQUE**, the modern name of a deserted city in Mexico, in the narrow valley of the Otolum, in the north part of the state of Chiapas, 80 m. S. of the Gulf port of Carmen. About 30 m. away, on the left bank of the Usumacinta river, stand the ruins of Men-ché or Lorillard city. The original name of Palenque has been lost, and its present name is taken from the neighbouring village, Santo Domingo del Palenque. Unlike the dead cities of the Yucatán plains, Palenque is surrounded by wooded hills and overgrown by tropical vegetation.

There is less stone carving on the exterior walls, door jambs and pillars of the buildings than on those of the Yucatán Peninsula; this is due to the harder and more uneven character of the limestone. Probably owing to the same cause, there is less cutting in the walls, the Palenque builders using plaster to obtain smooth surfaces. There is, however, considerable carving on the interior walls, the best specimens being on the tables, affixed to the walls with plaster. Modelling in stucco was extensively used. A few terra-cotta images have been found. Paint and coloured washes were liberally used to cover plastered surfaces and for ornamentation, and paints seem to have been used to bind plastered surfaces. The Palenque builders apparently used nothing but stone tools in their work.

The so-called Great Palace consists of a group of detached buildings, apparently ten in number, standing on two platforms of different elevations. Some of the interior structures and the detached one on the lower southern terrace are in a fair state of preservation. The plan of construction shows three parallel walls enclosing two corridors covered with the peculiar pointed arches or vaults characteristic of Palenque. The buildings appear to have been erected at different periods. A square tower rises from a central part of the platform to a height of about 40 ft., divided into a solid masonry base and three storeys connected by interior stairways. The Temple of Inscriptions, one of the largest and best preserved, is distinguished chiefly by its pillars, which form a semicircle; the steps leading up to the temple, and its exterior is ornamented with figures in stucco, the outer faces of the four pillars in front having life-size figures of women with children in their arms. The small Temple of Beau Relief stands on a narrow ledge of rock against the steep slope of the mountain. Its most important feature is a large stucco bas-relief, occupying a central position on the back wall of the sanctuary. It consists of a single figure, seated on a throne, beautifully modelled both in form, drapery and ornaments, with the face turned to one side and the arms outstretched, and is reproduced by H. H. Bancroft. The temples on the east side of the Otolum are distinguished by tall narrow vaults, perforated by numerous square openings giving the appearance of coarse lattice work. The Temple of the Sun stands upon a comparatively low pyramidal foundation. The interior consists of the usual pair of vaulted corridors. The sacred tablet on the back wall of the sanctuary is carved in low relief in limestone, and consists of two figures, apparently a priest and his assistant making offerings. There are rows of hieroglyphics on the sides and over the central design. The Temple of the Cross is a larger structure of similar design and construction. The tablet belonging to this temple has excited controversy, because the design contains a representation of a Latin cross. The Temple of the Cerro, called that of the Cross No. 2, because its tablet is very similar to that just mentioned, stands back against the slope of the mountain, and is in great part a ruin. (For history and further details see CENTRAL AMERICA; § Archaeology.)

**PALERMO** (Greek, Πάλερμος; Latin, Panormus, Panormus), a city of Sicily, capital of a province of the same name, in the kingdom of Italy, and the see of an archbishop. Pop. (1906), town 264,036, commune 323,747. The city stands in the N.W. of the island, on a small bay looking E., the coast forming the chord of a semicircle of mountains which hem in the campagna of Palermo, called the Conca d’Oro. The most striking point is the mountain of Hierce, now called Pellegrino (from the grotto of Santa Rosalia, a favourite place of pilgrimage) at the N. of this semicircle; at the S.E. is the promontory of Zaffarano, on which stood Soluntum (q.v.).

A neolithic settlement and necropolis were discovered in 1857 at the foot of Monte Pellegrino, on the N.E. side (E. Salinas in Notizie degli Scavi, 1907, 307). Palermo has been commonly thought to be an original Phoenician settlement of unknown date (though its true Phoenician name is unknown), but Holm (Archivio storico siciliano, 1880, iv. 421) has suggested that the settlement was originally Greek. There is no record of any Greek colonies in that part of Sicily, and Panormus certainly was Phoenician as far back as history can carry us. According to Thucydides (vi. 2), as the Greeks colonized the E. of the island, they took over its name of Panormus, and concentrated themselves at Panormus, Motye, and Soluntum. Like the other Phoenician colonies in the west, Panormus came under the power of Carthage, and became the head of the Carthaginian dominion in Sicily. As such it became the centre of that strife between Europe and Africa, between Aryan and Semitic man, in its later stages between Christendom and Islam, which forms the great interest of Sicilian history. As the Semitic head of Sicily, it stands opposed to Syracuse, the Greek head. Under the Carthaginian it was the head of the Semitic part of Sicily; when, under the Saracen all Sicily came under Semitic rule, it was the chief seat of that rule. It was thrice won for Europe, by Greek, Roman and Norman conquerors—in 276 B.C. by the Epiran king Pyrrhus, in 254 B.C. by the Roman consul Aulus Attilius and Gnaeus Cornelius Scipio, and in A.D. 1071 by Robert Guiscard and his brother Roger, the first count of Sicily. After the conquest by Pyrrhus the city was soon recovered by Carthage, but this first Greek occupation was the beginning of a connexion with western Greece and its islands which was revived under various forms in later times. After the Roman conquest an attempt to recover the city for Carthage was made in 126 B.C. (though it withstood the N.W. invasion (see PUNIC WARS). Later, in the First Punic War, Hamilcar Barca was encamped for three years on Hierce or Pellegrino, but the Roman possession of the city was not disturbed. Panormus received the privileges of autonomy and immunity from taxation. It seems probable that at the end of the republic the coinage for the west of Sicily was struck here (Mommsen, Röm. Münzwesen, 665). A colony was sent here by Augustus, and the place remained of considerable importance, though inferior to Catana. A fortunate chance has preserved to us a large number of the inscriptions set up in the Forum (Mommsen, Corpus inscr. lat. x. 752). The town was taken by the Vandal Genseric in a.d. 440. It afterwards became a part of the East-Gothic dominion, and was recovered for the empire by Belisarius in 535. It again remained a Roman possession for exactly three hundred years, till it was taken by the Saracens in 835. Panormus now became the Moslem capital. In 1062 the Pisan fleet broke through the channel of the harbour and carried off much spoil, which was spent on the building of the great church of C. After the Norman conquest the city remained for a short time in the hands of the dukes of Apulia. But in 1193 half of the town was ceded to Count Roger, and in 1195 the rest was ceded to the second Roger. When he took the kingly title in 1190 it became "Prima sedes, corona regis, et regni caput."

1 The coins bearing the name of Panormus are no longer assigned to Panormus; but certain coins with the name PALE (Zir; about 410 B.C.) belong to it.
During the Norman reigns Palermo was the main centre of Sicilian history, especially during the disturbances in the reign of William the Bad (1154-1166). The emperor Henry VI. entered Palermo in 1194, and it was the chief scene of his cruelties. In 1198 his son Frederick, afterwards emperor, was crowned there. After his death Palermo was for a moment a commonwealth. It passed under the dominion of Charles of Anjou in 1266. In the next year, when the greater part of Sicily revolted on behalf of Conradin, Palermo was one of the few towns which were held for Charles; but the famous Vespers of 1282 put an end to the Angevin dominion. From that time Palermo shared in the many changes of the Sicilian kingdom. In 1535 Charles V. landed there on his return from Tunis. The last kings crowned at Palermo were Victor Amadeus of Savoy, in 1713, and Charles III. of Bourbon, in 1735. The loss of Naples by the Bourbons in 1798, and again in 1806, made Palermo once more the seat of a separate Sicilian kingdom. The city rose against Bourbon rule in 1820 and in 1848. In 1860 came the final deliverance, at the hands of Garibaldi; but with it came also the yet fuller loss of the position of Palermo as the capital of a kingdom of Sicily.

Site.—The original city was built on a tongue of land between two inlets of the sea. There is no doubt that the present main street, the Cassaro (Roman castrum, Arabic Kasr), Via Marmorea or Via Toledo (Via Vittorio Emmanuele), represents the line of the ancient town, with water on each side of it. Another peninsula with one side to the open sea, meeting as it were the main city at right angles, formed in Polybius's time the Neapolis, or new town, in Saracen times Khaleda, a name which still survives in that of Calsa. But the two ancient harbours have been dried up; the two peninsulas have met; the long street has been extended to the present coast-line; a small inlet, called the Cala, alone represents the old haven. The city kept its ancient shape till after the time of the Norman kings. The old state of things fully explains the name Iàròpòs.

There are not many early remains in Palermo. The Phoenician and Greek antiquities in the museum do not belong to the city itself. The earliest existing buildings date from the time of the Norman kings, whose palaces and churches were built in the Saracenic and Byzantine styles prevalent in the island. Of Saracen works actually belonging to the time of Saracen occupation there are no whole buildings remaining, but many inscriptions and a good many columns, often inscribed with passages from the Koran, which have been used up again in later buildings, specially in the porch of the metropolitan church. This last was built by Archbishop Walter (fl. 1170)—an Englishman sent by Henry II. of England as tutor to William II. of Sicily—in an ancient basilica, on the site of an Arab castle which, on the Saracen conquest became a mosque, and on the Norman conquest became a church again, first of the Greek and then of the Latin rite. What remains of Walter's building is a rich example of the Christian-Saracen style, disfigured, unfortunately, by the addition of a totally unsuitable dome by Ferandino Fuga in 1781-1801. This church contains the tombs of the emperor Frederick II. and his parents—massive sarcophagi of red porphyry with canopies above them—and also the royal throne, higher than that of the archbishop: for the king of Sicily, as hereditary legate of the see of Rome, was the higher ecclesiastical officer of the two. But far the best example of the style is the chapel of the king's palace (cappella palatina), at the west end of the city. This is earlier than Walter's church, being the work of King Roger in 1143. The wonderful mosaics, the wooden roof, elaborately fretted and painted, and the marble incrustation of the lower part of the walls and the floor are very fine. Of the palace itself the greater part was rebuilt and added in Spanish times, but there are some other parts of Roger's work left, specially the hall called Sala Normanna.

Alongside of the churches of this Christian-Saracen type, there is another class which follows the Byzantine type. Of these the most perfect is the very small church of San Cataldo. But the best, much altered, but now largely restored to its former state, is the adjoining church of La Martorana, the work of George of Antioch, King Roger's admiral. This is rich with mosaics, among them the portraits of the king and the founder. Both these and the royal chapel have several small cupolas, and there is a still greater display in that way in the church of San Giovanni degli Eremiti, which it is hard to believe never was a mosque. It is the only church in Palermo with a bell-tower, itself crowned with a cupola.

Most of these buildings are witnesses in different ways to the peculiar position of Palermo in the 12th century as the "city of the threefold tongue," Greek, Arabic, and Latin. King Roger's sun dial in the palace is commemorated in all three, to be noticed that the three inscriptions do not translate one another. In private inscriptions a fourth tongue, the Hebrew, is also often found. For in Palermo under the Norman kings Christians of both rites, Mahommedans and Jews were all allowed to flourish after their several fashions. In Saracen times there was a Slavonic quarter on the southern side of the city, and there is still a colony of United Greeks, or more strictly Albanians.

The series of Christian-Saracen buildings is continued in the country houses of the kings which surround the city, La Fava and Mimmenro, the works of Roger, and the better known Ziza and Cuba, the works severally of William the Bad and William the Good. The Saracenic architecture and Arabic inscriptions of these buildings have often caused them to be taken for works of the ancient ambers; but the inscriptions of
themselves prove their date. All these buildings are the genuine work of Sicilian art, the art which had grown up in the island through the presence of the two most civilized races of the age, the Greek and the Saracen. Later in the 12th century the Cistercians brought in a type of church which, without any great change of mere style, has a very different effect, a high choir taking in some sort the place of the cupola. The greatest example of this is the neighbouring metropolitan church of Monreale (q.v.); more closely connected with Palermo is the church of San Spirito, outside the city on the south side, the scene of the Vespers.

Domestic and civil buildings from the 12th century to the 15th abound in Palermo, and they present several types of genuine national art, quite unlike anything in Italy. Of palaces the finest is perhaps the massive Palazzo Chiaromonte, now used as the courts of justice, erected subsequently to 1507. One of the halls has interesting paintings of 1537-1580 on its wooden ceiling; and in the upper storey of the court is a splendid three-light Gothic window. The later houses employ a very flat arch, the use of which goes on in some of the houses and smaller churches of the Renaissance. S. Maria della Catena may be taken as an especially good example. But the general aspect of these later stills dating from mere Spanish times. Still many of the houses are remarkable heavy balconies. The most striking point in the city is the central space at the crossing of the main streets, called the Quattro Cantoni. Two of the four are formed by the ancient Via Marmorea, but the Via Macqueda, which supplies the other two, was cut through as a mass of small streets in Spanish times.

The city walls are now to a great extent removed. Of the gates only two remain, the Porta Nuova and the Porta Felice; both are fine examples of the baroque style, the former was erected in 1584 to commemorate the return of Charles V. fifty years earlier, the latter in 1582. Outside the walls new quarters have sprung up of recent years, and the Teatro Massimo and the Politeama Garibaldi; the former (begun by G. B. Basile and completed by his son in 1897) has room for 3200 spectators and is the largest in Italy.

The museum of Palermo, the richest in the island, has been transferred from the university to the former monastery of the Filippini. Among the most important are the objects from prehistoric tombs and the archaeological and historical relics, including several metopes with reliefs, which are of great importance as illustrating the development of Greek sculpture. None of the numerous Greek vases and terra-cottas is quite of the first class, though the collection is important. The bronzes are few, but include the famous ram from Syracuse. There is also the Casuccini collections of Etruscan sarcophagi, sepulchral urns and pottery. Almost the only classical antiquities from Palermo itself are Latin inscriptions of the imperial period, and two large coloured mosaics with figures found in the Piazza Vittoria in front of the royal palace in 1899: in 1906 excavations in the same square led to the discovery of a large private house, apparently of the 2nd or 3rd century A.D., to which these mosaics no doubt belonged. Of greater local interest are the medieval and Renaissance sculptures from Palermo itself, a large picture gallery, and an extensive collection of Sicilian majolica, &c.

The university, founded in 1779, rose to importance in recent years (from 300 students in 1872 to 1495 in 1897), but has slightly lost in numbers since. The city wears a prosperous and comfortable air. Tart Marit, or esplanade at the south of the town, affords a fine sea front with a view of the bay; near it are beautiful public gardens. In the immediate neighbourhood of the city are the oldest church in or near Palermo, the Lepers' church, founded by the first conqueror or deliverer, Count Roger, and the bridge over the forsaken stream of the Oreo, built in King Roger's day by the admiral George. There are also some later medieval houses and towers of some importance. These all lie on to the south of the city, towards the hill called Monte Griffone (Griffon-Greek), and the Giant's Cave, which has furnished rich stores for the palaeontologist. On the other side, towards Pellegrino, is the new harbour of Palermo, round which a new quarter has sprung up, including a yard capable of building ships up to 475 ft. in length, and a dry dock for vessels up to 593 ft.

The steamship traffic at Palermo in 1906 amounted to 2053 vessels, with a total tonnage of 2,405,851 tons. Palermo is one of the two main quarters of the shipping of the Nuova Generale Italiana, the chief Italian steamship company. The principal imports were 36,367 tons of timber (a large increase on the normal figures), 21,401 tons of wheat and 1,350,380 tons of coal. The chief exports were 116,400 gallons of oil, 75,835 tons of umbric and 122,023 tons of oranges and lemons, including most of its valuable rates hypothesized to the meeting of old debts, the munificence of Palermo has embarked upon municipal ownership of trading in various ways.

The plain of Palermo is very fertile, and well watered by springs and streams, of the latter of which the Oreo is the chief. It is planted with orange and lemon groves, the products of which are largely exported, and with many palm-trees, the fruit of which, however, does not attain maturity. It contains many villas of the wealthy inhabitants of Palermo, among the most beautiful of which is La Favorita, at the foot of Monte Pellegrino on the west, belonging to the Crown.

The Palitana and the Politeama are works dealing with Sicily generally, the established local work on Palermo is Descrittione di Palermo antico, by Salvatore Morso (2nd ed., Palermo, 1827). Modern research and criticism have been applied in Die mittelalterliche Kunst in Palermo, by E. A. Freeman (London, 1870). The description of Palermo in the second volume of Geffelin's guide-book, Unter-Italien und Sicilien (Leipzig), leaves nothing to wish for. Various articles in the Archivio storico siciliano and the series of Documents per servire alla storia della Sicilia, both published by the Società siciliana per la storia patria, may also be consulted. (E. A. F.; T. A.)

PALE, an old Italian goddess of flocks and shepherds. The festival called Parilia (less correctly Palilia) was celebrated in her honour at Rome and in the country on the 21st of April. In this festival Pales was invoked to grant protection and increase to flocks and herds; the shepherds entreated forgiveness for any unintentional profanation of holy places of which their flocks might have been guilty, and leaped three times across bonfires of hay and straw (Ovid, Fasti, iv. 731-805). The Parilia was not only a herdsman's festival, but was regarded as the birthday celebration of Rome, which was supposed to have been founded on the same day. Pales plays a very subordinate part in the religion of Rome, even the sex of the divinity being uncertain. A male Pales was sometimes spoken of, corresponding in some respects to Pan; the female Pales was associated with Vesta and Anna Perenna.

PALESTINE, a geographical name of rather loose application. Etymological strictness would require it to denote exclusively the narrow strip of coast-land once occupied by the Philistines, from whose name it is derived. It is, however, conventionally used as a name for the territory which, in the Old Testament, is claimed as the inheritance of the pre-exilic Hebrews; thus it may be said generally to denote the southern third of the province of Syria. Except in the west, where the country is bordered by the Mediterranean Sea, the limit of this territory cannot be laid down on the map as a definite line. The modern subdivisions under the jurisdiction of the Ottoman Empire are in this region determined with less antiquity, and hence do not afford a boundary by which Palestine can be more exactly defined exactly from the rest of Syria in the north, or from the Sinaitic and Arabian deserts in the south and east; nor are the records of ancient boundaries sufficiently full and definite to make possible the complete demarcation of the country. Even the convention above referred to is inexact: it includes thePhilistia, claimed but never settled by the Hebrews, and excludes the outlying parts of the large area claimed in Num. xxiv. as the Hebrew possession (from the "River of Egypt" to Hamath). However, the Hebrews themselves have preserved, in the

1 The figures for 1905 (40,005 tons, almost entirely from Russia) were abnormally high, while those for 1906 are corresponding below the average.
proverbial expression "from Dan to Beersheba" (Judg. xx. 1, &c.), an indication of the normal north-and-south limits of their land; and in defining the area of the country under discussion it is this indication which is generally followed.

Taking as a guide the natural features most nearly corresponding with its limits, we may describe Palestine as the strip of land extending along the eastern shore of the Mediterranean Sea from the mouth of the Litany or Kasimya River (33° 20' N.) southward to the mouth of the Wadi Ghuzzah; the latter joins the sea in 31° 28' N., a short distance south of Gaza, and runs thence in a south-easterly direction so as to include on its northern side the site of Beersheba. Eastward there is no such definite border. The River Jordan, it is true, marks a line of delimitation between Western and Eastern Palestine; but it is practically impossible to say where the latter ends and the Arabian desert begins. Perhaps the line of the pilgrim road from Damascus to Mecca is the most convenient possible boundary. The total length of the region is about 140 m.; its breadth west of the Jordan ranges from about 23 m. in the north to about 80 m. in the south. According to the English engineers who surveyed the country on behalf of the Palestine Exploration Fund, this part of the Jordan is 170 m. wide. About one-third of the area of the Jordan, owing to the want of a proper survey, no figures so definite as these are available.

The limits adopted are from the south border of Hermon to the mouth of the Mojib (Arnon), a distance of about 140 m.; the whole area has been calculated to be about 3800 sq. m. The territory of Palestine, Eastern and Western, is thus equal to rather more than one-sixth the size of England.

There is no ancient geographical term that covers all this area. Till the period of the Roman occupation it was subdivided into independent provinces or kingdoms, different at different times (such as Philistia, Canaan, Judah, Israel, Bashan, &c.), but never united under one collective designation. The extension of the name Palestine beyond the limits of Philistia proper is not older than the Byzantine Period.

Physical Features.—Notwithstanding its small size, Palestine possesses peculiar physical characters no less remarkable as to itself sufficient to mark it out as a country of especial interest. The bordering regions, moreover, are as varied in character as is the country itself—sea to the west, a mountainous and sandy desert to the south, a lofty steppe plateau to the east, and the great masses of Lebanon to the north. In describing the general physical features of the country, the most significant point to notice is that (though it falls westward to the sea and rises eastward to an elevation of 1000 m. or more) the chain of ranges is here sharply interrupted by the deep fissure of the Ghor or Jordan valley; which, running from north to south—for the greater part of its length depressed below sea-level—forms a division in the country as divided into two parts, and as divided into the two parts, the function of the river Jordan in Palestine offers a strange contrast, often remarked upon, to that of the Nile in Egypt. The former is of no use for irrigation, except in the immediate neighborhood of its mouth, while the latter, the life-giving river of the land of the Pharaohs, by means of its branches, which run into the sea south of Acre, and the Wadi Mukatta', or Kishon, which joins the sea at Haifa. On the east may be mentioned the Wadi el-Rubadiya, the Wadi el-Hamam and the Wadi el-Buttauf, which run towards the Sea of Galilee and flow into it. On the west the valley of the Jordan is divided into the valleys of Kasimya and Jaffa, the latter containing the river that flows from the fine spring called 'Ain Jalud.

The great plain of Esdraelon, which forms what from the earliest times has been recognized to be the easiest entrance to the interior of the country, cuts abruptly through the mountain system, and so divides it into two regions. Each of these may be subdivided into two regions presenting their own special peculiarities.

2. The Galilean Mountains, of the north of Esdraelon, fall into three distinct, but closely associated, regions, the westernmost of which, the plain of Beersheba, presents a singular contrast to the Sea of Galilee. The northern region (Upper Galilee) is virtually an outlier of the Lebanon Mountains. At the north end is an elevated plateau, draining into the Kasimya. The mountains are broken by the river, which has a peculiar course; it runs ninety miles down to the Mediterranean. The face toward the Jordan valley is lofty and steep. The highest point is Jebel Jermak, 3343 ft. above the sea; about it, on the eastern and southern sides, lie lofty precipitous regions. The region is fruitful, and in those well wooded; it is beyond question the most picturesque part of Palestine. The southern region (Lower Galilee) shows somewhat different characteristics. It consists of chains of comparatively low hills, for the greater part running east and west, enclosing a number of elevated, but low, plateaus, with deep ravines and steep precipitous sides. An approach to Haifa is possible from the north and east, but it is a tedious journey. A road from the northern Negev to the Jordan passes through this region, and penetrates two and two and a half miles into the Sea of Galilee. Lower Galilee is the region of the Israelitish unification, and the site of ancient Shechem and Sepphoris (Judg. vi. 12). Eastward the country falls to the level of the Ghor by a succession of steps, among which the lava-covered Sahel el-Ahma may be mentioned, which lies west of the cliffs overhanging the Sea of Galilee. In many places this volcanic region is thrown into a series of amphitheatres. The present surface of Lower Galilee and that of the Sea of Galilee is divided into two regions by a range of hills, including the Jabal el-Makmal (or Tabor), 649 m. above sea-level, and the Jabal el-Birah, the latter containing the river that flows from the fine spring called 'Ain Jalud. In Lower Galilee there is a narrow strip of land along the coast, which presents a remarkable contrast to the Sea of Galilee. East of the Wadi el-Rubadiya and Wadi el-Hamam, the district of Wadi el-Birah and the Wadi Jalud, the latter containing the river that flows from the fine spring called 'Ain Jalud.

The great plain of Esdraelon is one of the most important and striking of the natural features of Western Palestine. It is a large triangle, having its corners at Jenin, Jebel el-Tur, and the outlet of the Megiddo—Nahr Belz—highway, and extending east and west to a great distance, its greatest breadth being one-third of a mile. The eastern coast of the Sea of Galilee is about 700 ft. above sea-level, while the great plain of Esdraelon is about 200 ft. below sea-level. The surface is flat, and in places almost impassable. The fertility of this region is proverbial. There are several small subsidiary plains that extend from it both north and south into the mountains and the Jordan valley. The eastern portion of this plain is cut by a broad valley running north-eastwards between Jebel Duhi, a range 15 m. long and 1690 ft. high, on the one side, and Mt Tabor and the hills of Nazareth on the other side. East of the watershed of this valley there is a wide extensive plain which is divided into the districts of Samaria and Judea. In the first of these the mountain ranges are complex, appearing to radiate from a centre which lies Merj el-Ghuruk, a small plain about 4 m. east of the Jordan, and is marshy in the rainy season. Connected with it are other small plains unnecessary to enumerate. For the greater part the
PALESTINE

[PHYSICAL FEATURES]

principal mountains are near the watershed; they include Jebel Fuku'a (Gilboa), a range that forms the watershed at the eastern extremity of the plain of Esdraelon. The range of Carmel (highest point 1810 ft.) must also be included in this district; it runs from the Judaean range. On the eastern side of the watershed the most important feature is perhaps the great valley system that connects the Mukhnah (the plain south of Nablus) with the Ghor—be
doing after the important and abundantly watered Wadi Fara. Tell 'Asur stands a short distance north of Beitein (Bethel). South of it is the long zigzag range known as Jebel el-Kuds, named from Jerusalem (el-Kuds) the chief town built upon it. The highest point is Nebi Samwil (Mizpah), 2985 ft. above the sea, north of Jerusalem. This city itself stands at an altitude of 2900 ft. To the south of it begins the subdivision of the Judaean mountains now known as Jebel el-Khalil, from Hebron (el-Khalil), which stands in an elevated basin some 500 ft. above the altitude of Jerusalem; it is here that the Judaean Mountains attain their greatest height. South of Hebron the ridge gradually becomes lower, and finally breaks up and loses itself in the southern desert.

On the west side of the watershed the mountainous district extends about half way to the sea, broken by deep valleys and passes. Among these the most im-
portant are the Wadi Selman (Valley of Aijalon) which seems to have been the principal route to Jerusalem in ancient times. The Wadi Isma'in south of this, along which runs the modern carriage road from Jaffa to Jerusalem; and the Wadi es-Surat, a higher section of the bed of the Nahar Rubin, along which now runs the railway line; further to the south we may mention the Wadi es-Sunt, which opens up the country from Tell es-Safi (Gath?) eastward.

Between the mountainous country of Judaea and the maritime plain is an undulating region anciently known as the Shephelah. It is composed of horizontal strata of limestone, forming groups of hills intersected by a network of small and fertile valleys. In this region, which is of great historical importance, are the remains of many ancient cities. The adjacent part of the maritime plain is composed of a rich, light brown loamy soil. Although cultivated with most primitive appliances, and with little or no attempt at irrigation or artificial fertilisation, the average yield is eight- to twelve-fold annually. This part of the plain is (in European nomenclature) divided into two at the latitude of Jaffa, that to the north being the plain of Sarona (Sharon), the southern half being the plain of the Phalasites.

On the east side of the watershed the ground slopes rapidly from its height of 2500 ft. above sea-level to a maximum depth of 1700 ft. below sea-level, within a distance of about 20 m. It is a waste, desert of water and with the scanty vegetation. It has never been brought into cultivation; but in the first Christian centuries the caves in its valleys were the chosen refuge of Christian monasticism. It descends to the level of the Ghor by terraces, deeply cut through by profound ravines such as the Wadi es-Suweinit, Wadi Keft, Wadi Dabab, Wadi en-Nar (Kedron) and Wadi el 'Arejeh.

The southern district, which includes the white marl region of Beersheba, was in ancient times the Negeb. It is a wide steppes region which (though it contains many remains of ancient towns and settlements, and was evidently at one time a territory of great importance) is now almost entirely inhabited by nomads. It is the chief source of the red sandstone which is exported under the name of Negeb sand. The Negeb is also a name applied to the southern portion of the shaggy range which extends from Nablus to the Wadi el 'Arejeh, and is named after the Saharonit, the Semitic race of its inhabitants. It is a district of great natural beauty, with its great white and blue mountains.
by the officers of the Palestine Exploration Fund. A good deal of work has been done by individual travellers, but the material for a full description of its physical character is as yet lacking. Two great rivers, the Yarmuk (Hieromax) and the Zerka (Jabbok), divide the country into two districts. The Jordan (Yarmuk) (Bashan, q.v.) with the Joshan of it; Jebel Aljun (Gilgal, q.v.); and the Belka (the southern portion of Galeed and the ancient territory of the tribe of Reuben). The latter extends southward to the Mojit, which, as we have already seen, is the southern boundary of the Jordanian plateau.

It is a matter of dispute whether the Jordanian plateau should be included within Palestine proper, accepting its definition as the "ancient Hebrew territory." It is a large volcanic region, entirely covered with volcanic deposits and rocks, and rising to a height of 2,000 ft. above sea level. The Jordanian plateau forms a large area of rough and barren land, and is divided by the Jordan River, which runs in lines from north to south, through the region of the Jordanian plateau to the Ghor, and from a long distance are conspicuous features in the landscape. The soil is fertile, and there are many cultivated plains. In the north and central parts of the Jordanian plateau, and South of the Yarmuk the formation is Cretaceous, Haranian basalt being found only in the eastern portion. That region is much more mountainous than Haran. South of the Zerka the country is elevated in Jebel Oh, a peak of Jebel el Jid' ("the Mountain of Gilgal"), 3,590 ft. high. From this point southward the country assumes the appearance which is familiar to those who have visited the Sinai Peninsula, with the western part of the region, the "western desert," being the most barren and desert-like. The western desert is the most barren and desert-like part of the country, and it is noteworthy that a part of it may be described as the "Jewish desert." The eastern part of the Jordanian plateau is a region of great variety, and is marked by the presence of many lakes, such as Jebel Shihan (2,781 ft.) in the north and Jebel Nbaa (Nebo, 2,643 ft.), conspicuous above the level of the ridge by reason of superior height.

Geology. — The oldest rocks consist of gneiss and schist, penetrated by dikes and bosses of granite, syenite, porphyry and other intrusives of similar character. There are certain rock formations which are probably of Haranian age, and they form a large area of the country. There are also many sandstone and conglomerate formations, and these are found in the vicinity of the Jordan River, and in the southern part of the country.

Climate. — Palestine belongs to the sub-tropical zone; at the summer solstice the sun is ten degrees south of the zenith. The length of the day ranges from ten to fourteen hours. The great variety of altitude and of surface characteristics gives rise to a considerable diversity of climate, and it may be stated that the mean annual temperature is 70° F., the normal extreme being about 50° to about 90°. The harvest ripens about a fortnight earlier than among the mountains. Citrons and oranges flourish, and the latter do not fruit abundantly, but in the winter they are very soft.

The rainfall is rather lower than among the mountains. In the mountainous regions the mean annual temperature is about 62°, but there is a great range of variation. In winter there is often torrential rain, and there are occasional heavy snowfalls. The winter of 1910-11 was particularly severe, and in exceptional years as much as 10 in. in excess of this figure has been recorded. The vine, fig and olive grow well in this region. The climate of the Ghor, again, is different. Here the temperature may rise as high as 130° F. The rainfall is scanty, but as no civilized person inhabits the southern end of the Jordan valley throughout the year, and it has hitherto proved impossible to establish self-registering instruments, no systematic meteorological observations have been taken. In Eastern Palestine there is even a greater range of temperature; the loftier heights are covered in winter with snow. The thermometer may range within twenty-four hours from freezing-point to 80° F.

The rainy season begins about the end of November, usually with a downpour of snow in the mountains. The rain at this part of the year is the "rainy season" of the Old Testament. The earth, baked hard by the summer heat, is thus softened, and ploughing begins at once. The wettest month, as indicated by meteorological observations, is October, and March is also a very wet month. In April the rains come to an end (the "latter rains") and the winter crops receive their final fertilization. The winter crops (barley and wheat) are harvested in June, and the summer crops (melon, grapes, olives, &c.) are fertilized by the "dews" which are one of the most remarkable climatic features of the country and to a large extent are due to the total lack of rain for the greater part of the year. These crops are harvested from August to October.

Water Supply. — Notwithstanding the long drought, it must not be supposed that Palestine is a waterless country, except in certain districts. There are occasional heavy rains, and some parts of the country are provided with natural springs and springs. Perennial streams are, and in the recent geological ages always have been, rare in the country. The whole face of the land is pitted with ancient cisterns; and, indeed, many hillside cisterns are the only water-bearing reservoirs which can be found, and have been known for some years. These cisterns are bell-shaped or bottle-shaped excavations, with a narrow circular shaft in the top, hollowed in the rock and lined with cement. Besides these, more ambitious works are to be found, and there are numerous aqueducts, both ancient and modern, which bring water into this country. There are also hot sulphur springs, which are utilized by the people of the country. These aqueducts, as well as countless numbers of now leaky cisterns, could with little difficulty be brought into use again, and would greatly enhance the fertility of the country. The most abundant springs in Palestine are the sources of the Jordan at Banias and at Tell el-Kadi. A considerable number of springs in the country are brackish, being charged with some of the brine from the Dead Sea. The most important domestic animals are the sheep, goat, and the horse; the breed of oxen is small and poor. The camel, the horse and the donkey are the draught animals; the flesh of the first

1 See Lorret, La Mer Morte (Paris, 1877); E. Hurl, Mount Seir, Sinai and Western Palestine (London, 1885); and Memoir on the Geology and Geography of Arabia Petraea, Palestine and adjoining Districts (London, 1886).
is eaten by the poorer classes, as is also occasionally that of the second. The dogs, which prowl in large numbers round the streets of towns and villages, are scarcely domesticated; much the same is true of the cats. Wild cats, cheetahs and leopards are found, but are very rare, especially in the latter. The jay, which inhabited the country in the time of the Hebrews, is now extinct. The most important wild animals are the hyena, wolf (now comparatively rare), fox and jackal. Bats, various species of rodents, and gophers are not uncommon, as is the larger form of vulture, the black vulture. Among the most characteristic birds may be mentioned eagles, vultures, owls, partridges, bee-eaters and hoopoes; singing birds are on the whole uncommon. Snakes—many of them venomous—are numerous, as also are many varieties of lizards. The crocodile is seen (but now very rarely) in the Nahr ez-Zerka. Scorpions and large spiders are a universal pest.

The flora of Palestine has a considerable range and variety, owing to the variation in local climatic conditions. In the Jordan valley, the vegetation has a semi-tropical character, consonant with the great heat, which here is normal. The coast-plain has another type, i.e. the ordinary vegetation of the Mediterranean littoral. In the mountains the flora is, naturally, scantier than in these two main regions, but even here there is a rich variety. In all parts of the country the contrast between the landscape in early spring and later, when the cessation of rains and the increase of heat has burnt up the vegetation, is very remarkable.

Population.—The inhabitants of Palestine are composed of a large number of elements, differing widely in ethnological affinities, language and religion. It may be interesting to mention that the number of different languages spoken in the country in the 20th century is a list of no less than fifty languages, spoken in Jerusalem as vernaculars, was there drawn up by a party of men whose various official positions enabled them to possess accurate information on the subject. It is therefore no easy task to write concisely and at the same time with sufficient fullness on the ethnology of Palestine.

There are two classes into which the population of Palestine can be divided—the nomadic and the sedentary. The former is especially characteristic of Eastern Palestine, though Western Palestine also contains its full share. The pure Arab origin of the Bedouins is recognized in common conversation in the country, the word "Arab" being almost restricted to denote these wanderers, and seldom applied to the dwellers in towns and villages. It should be mentioned that there is another, entirely independent, nomad race, the despised Nowar, who correspond to the gipsies or tinkers of European countries. These people live under the poorest conditions, by doing smith's work; they speak among themselves a Romani dialect, much contamined with Arabic in its vocabulary.

The sedentary population of the country villages—the fellahin, or agriculturists—is, on the whole, comparatively unmixed; but traces of various intrusive strains assert themselves. It is by no means unreasonable to suppose that there is a fundamental Canaanite element in this population: the "hewers of wood and drawers of water" often remain undisturbed through successive occupations of a land; and there is a remarkable correspondence of type between many of the modern fellahin and skeletons of ancient inhabitants which have been recovered in the course of excavation. New elements no doubt came in under the Assyrian, Persian and Roman dominations, and in more recent times there has been much contamination. The spread of Islam introduced a very considerable Neo-Arabic influence. The most noticeable intrusive strains were kindred to the Yaman tribe, those from northern Arabia the Kais (Qais). These two divisions absorbed the previous peasant population, and still nominally exist; down to the middle of the 19th century they were a fruitful source of quarrels and of bloodshed. The two great classes were further subdivided into families, but these minor divisions are also being gradually broken down. In the 19th century the short-lived Egyptian government introduced into the population an element from that country which still persists in the villages. These newcomers have not been completely assimilated with the villagers among whom they have found a home; the latter despise them, and discourage intermarriage.

Some of the larger villages—notably Bethlehem—which have always been leavened by Christianity, and with the development of industry have become comparatively prosperous, show tangible results of these happier circumstances in a higher standard of physique among the men and of personal appearance among the women. It is not uncommon in popular writings to attribute this superiority to a crusader strain—a theory which no one can possibly countenance who knows what miserable degenerates the half-breed descendants of the crusaders rapidly became, as a result of their immoral life and their ignorance of the sanitary precautions necessary in a trying climate.

The population of the larger towns is of a much more complex nature. In each there is primarily a large Arab element, consisting for the greater part of members of important and wealthy families. Thus, in Jerusalem, much of the local importance is lent by the families of El-Khaldi, El-Husseini and one or two others, who derive their descent from the heroes of the early days of Islam. The Turkish element is small, consisting exclusively of officials sent individually from Constantinople. There are very large contingents from the Mediterranean countries, especially Armenia, Greece and Italy, principally engaged in trade. The extraordinary development of Jewish colonization has since 1870 affected a revolution in the balance of population in some parts of the country, notably in Jerusalem. There are several residents of the country from the more eastern parts of Asia—if we except the Turkoman settlements in the Janul, a number of Persians, and a fairly large Afghan colony that since 1903 has established itself in Jaffa. The Mutâwileh (Motawila), who form the majority of the inhabitants of the villages north-west of Galilee, are probably long-settled immigrants from Persia. Some tribes of Kurds live in tents and huts on the Lake Huleh. If the inmates of the country, except these establishments be excluded, comparatively few from northern or western Europe will remain: the German "Templar" colonies being perhaps the most important. There must also be mentioned a Bosnian colony established at Caesarea Palestina, and the Circassian settlements placed in certain centres of Eastern Palestine by the Turkish government in order to keep a restraint on the Bedouin; the latter are also found in Galilee. There was formerly a large Sudanean and Algerian element in the population of some of the large towns, but these have been much reduced in numbers since the beginning of the 20th century: the Algerians however still maintain themselves in parts of Galilee.

The most interesting of all the non-Arab communities is the country, however, is without doubt the Samaritan sect in Nablus (Shechem); a gradually disappearing body, which has maintained an independent existence from the time when they alone seemed to occupy the land left waste by the captivity of the kingdom of Israel.

The total population of the country is roughly estimated at 650,000, but no authentic official census exists from which satisfactory information on this point is obtainable. Some two-thirds of this number are Moslems, the rest Christians of various sects, and Jews. The largest town in Palestine is Jerusalem, estimated to contain a population of about 60,000. The other towns of above 10,000 inhabitants are Jaffa (45,000), Gaza (35,000), Safed (30,000), Nablus (25,000), Kerak (20,000), Hebron (18,500), Es-Salt (15,000), Acre (11,000), Nazareth (11,000).

The above remarks apply to the permanent population. They would be incomplete without a passing word on the non-permanent elements which at certain seasons of the year are in the principal centres the most conspicuous. Especially in winter and early spring crowds of European and American tourists, Russian pilgrims and Bohkharan devotees jostle one another in the streets in picturesque incongruity.

Political Divisions.—Under the Ottoman jurisdiction Palestine has no independent existence. West of the Jordan, and to about half-way between Nablus and Jerusalem, is the southern portion of...
PALESTINE

of Jerusalem, to which Nazareth with its immediate neighbourhood is added, so as to bring all the principal "Holy Places" under one jurisdiction. East of the Jordan the country forms part of the large vilayet of Damascus, with a capital at Damascus. Settlements.—Until 1892 communication through the country was entirely by caravan, and this primitive method is still followed over the greater part of its area. On the 26th of September of that year a railway between Jaffa and Jerusalem, with five intermediate stations, was opened, and the line was extended to Damascus, the coast and the mountains of Judaea. A railway from Haifa to Damascus was opened in 1905; it runs across the Plain of Esdraelon, enters the Chor at Beisan, then, turning northwards, intersects the Sea of Galilee and runs the valleys of the Yarmuk to join, at ed-Deira, the line of the third railway. This was undertaken in 1901 to connect Damascus with Mecca; in 1906 it was finished as far as Ma'an, and in 1908 the section to Medina was opened, a line which runs through the desert southwards to the oasis of Berenice. During the last decade of the 19th century. They are on the whole carelessly made and maintained, and are liable to go badly and more or less permanently out of repair in heavy rain. Of completed roads the most important are from Jaffa to Haifa, Jaffa to Nazareth and Jaffa to Gaza, and from Haifa to Jerusalem to Bethlehem with a branch to Hebron, Jerusalem to Khan Khublan —ultimately to be extended to Nablus; and Gaza to Beersheba. Other roads have been begun in Galilee (e.g., Haifa to Tiberias and to Nazareth) to connect the Port of Jaffa and the southern. For the rest there is a network of tracks, all practically impassable by wheeled vehicles, extending over the country and connecting the towns and villages one with another.

Leather goods and manufactures of importance in Palestine: the country is entirely agricultural. Although the processes are primitive and improvements are discouraged, both by the policy of the government and by the indifference and superstition of the people natural to the people themselves, fine crops of cereals are yielded, especially in the large wheat-lands of Haoran. Besides wheat, the following crops are to a greater or less extent cultivated — barley, millet, sesame, maize, beans, peas, lentils, kurkuri (a species of vetch used as camel-food) and, in some parts, cotton. 

The culture of the vine—formerly an important staple, as is proved by the countless ancient wine-presses scattered over the rocky hillsides of the whole country—fell to some extent into desuetude, not only on account of the great demand for wine, which, however, rapidly returning to favour, principally under Jewish auspices, and numerous vineyards now exist at different centres. All over the country are olive-trees, the fruit and oil of which are a staple product of the country; the trade is however hampered by the cost of transport to the interior, which has discouraged but has the unfortunate effect of encouraging destruction. Other fruit trees are abundant, though less so than those we have mentioned: such are pomegranates, peaches, almonds, peaches, and, in that country, the apricot. The grape is also grown in considerable quantities. The khurbar (carob) is common and yields a fruit eaten by the poorer classes. Of ordinary table vegetables a considerable quantity and variety are grown: such are the cabbage, cauliflower, salsify, artichoke, hellebore, rhubarb, lettuce, carrots, artichoke, &c. The potato is also grown in considerable quantities. Beside the agricultural there is a considerable pastoral industry, though it is principally confined to production for home consumption and not for export. The bread of the beasts of burden (donkeys, horses, camels) is chiefly in the hands of the Bedouin.

Of the manufactures the following call for mention: pottery (at Gaza, Ramleh and Jerusalem); soap (from olive oil, principally at Jerusalem and Jaffa); salt (from the Dead Sea), which is collected by large teams of donkeys; and paper, which is produced in a few factories. One industry of less importance is basket-making, weaving, and silk and cotton manufacture. Stone-quarrying has been fostered since 1900 by the great development of building at Jerusalem and other places. Wine is manufactured by several of the German and Jewish colonies and by some of the monastic establishments. Regular industrial works have been handicapped by competition with the tourist trade in its several branches—acting as guides and camp-followers, manu-
ufacture and sell of "souvenirs" (carved toys and trinkets in mother-of-pearl and olive-wood, forged antiquities and the like), and the analogous trade in objets de fide (rosaries, crosses, crude religious pictures, &c. for pilgrims. Travellers in the country, with their money recklessly, and these trades, at once easy and lucrative, are thus fatally attractive to the indolent Syrian and prejudicial to the best interests of the country. (R. A. S. M.)

History

I.—Old Testament History.

Palestine is essentially a land of small divisions, and its configuration does not fit it to form a separate entity; it "has never belonged to one nation and probably never will." Its position gives the key to its history. Along the west coast ran the great road for traders and for the campaigns which have made the land famous. The seaports (more especially in Syria, including Phoenicia), were well known to the pirates, traders and sea-powers of the Levant. The southernmost, Gaza, was joined by a road to the mixed peoples of the Egyptian Delta, and was also the port of the Arabian caravans. Arabia, in its turn, opens out into both Babylonia and Palestine, and a familiar route skirted the desert east of the Jordan into Syria to Damascus and Hamath. Damascus is closely connected with Galilee and Gilead, and has always been in contact with Mesopotamia, Assyria, Asia Minor and Armenia. Thus Palestine lay at the gate of Arabia and Egypt, and at the tail end of a number of small states stretching up to Asia Minor; it was an oasis, a well known commerce between Babylonia, Assyria, South Arabia and Egypt. The history of the Histories of Asia Minor, and of the Aegenean peoples. Consequently its history cannot be isolated from that of the surrounding lands. Recent research in bringing to light considerable portions of long-forgotten ages is revolutionizing those impressions which were based upon the Old Testament—the sacred writings of a small fraction of this great area; and a broad survey of the vicissitudes of this area furnishes a truer perspective of the few centuries which concern the biblical student. The history of the Israelites is only one aspect of the history of Palestine, and this is part of the history of a very closely interrelated portion of a world sharing many similar forms of thought and custom. It will be necessary here to approach the subject from a point of view which is less familiar to the biblical student, and to treat Palestine not merely as the land of the Bible, but as a land which has played a part in history for certainly more than 4000 years. The close of the Old Testament history (the book of Nehemiah) in the Persian age forms a convenient division between ancient Palestine and the career of the land under non-oriental influence during the Greek and Roman ages. It also marks the culmination of a lengthy historical and religious development in the establishment of Judaism and its inevitable rise. The most important data bearing upon the first great period are given elsewhere in this work, and it is proposed to offer here a more general survey. To the prehistoric ages belong the palaeolithic and neolithic flints, from the distribution of which an attempt might be made to give a synthetic sketch of early Palestinian man. A burial cave at Gezer has revealed the existence of a race of slight build and stature, muscular, with elongated crania, and thick and heavy skull-bones. The

1 A sanjaj is usually a subordinate division of a vilayet, but that of Jerusalem has been independent ever since the Crimean War. This change was made on account of the trouble involved in referring all complications (arising from questions relating to the political standing of the holy places) to the superior officials of Beirut or Damascus.

2 Sometimes imagined to be the "locusts" eaten by John the Baptist, on which account the tree is often called the locust-tree. But it was the insect which John used to eat; it is still eaten by the fellahin.
themselves, they were united by their common recognition of the Egyptian suzerain, their court of appeal, or in some short-lived attempts to withstand him. Thus, the Jebusites and a few towns on the coast, the real weight lay to the north, and especially in the state of Amor. It is an age of internal disorganization and of heavy pressure by land and by sea from Northern Syria and Asia Minor. The land seethes with excitement, and Palestine, wavering between allegiance to Egypt and intrigues with the great movements at its north, is unable to take any independent line of action. The letters vividly describe the approach of the enemy, and, in appealing to Egypt, abound in protestations of loyalty, complaints of the disloyalty of other kings and excuses for the writers’ suspicious conduct. Of exceptional interest are the letters from Jerusalem describing the hostility of the maritime coast and the disturbances of the Habiru (“allies”), a name which, though often equated with that of the Hebrews, may have no ethnological or historical significance. But Egypt was unable to help the loyalists, even ancient Mitanni lost its political independence, and the supremacy of the Hittites was assured. The history of the age illustrated by the Amarna letters is continued in the tablets found at Boghaz-keui, the capital of the old Hittite Empire. Subsequent Egyptian evidence records that Seti I. (c. 1320) of the XIXth Dynasty led an expedition into Palestine, but struggles with the Hittites continued until Rameses II. (c. 1300) concluded with them an elaborate treaty which left him little more than Palestine. Even this province was with difficulty maintained: the disturbances in the Levant and in Asia Minor (which belong to Aegean and Hittite history) and the revival of Assyria were reshap ing the political history of Western Asia.

Under Rameses III. (c. 1200–1160) we may recognize another age of disorganization in Palestine, in the movements with which the Philistines (q.v.) were concerned. Nevertheless, Egypt seems to have enjoyed a fresh spell of extended supremacy, and Rameses apparently succeeded in recovering Palestine and some part of Syria. But it was the close of a lengthy period during which Egypt had endeavoured to keep Palestine detached from Asia, and Palestine had realized the significance of a powerful empire at its south-western border. Somewhat later Tiglath-Pileser (c. 1100) pushed the limits of Assyrian suzerainty westwards over the lands formerly held by the great Hittite Empire. It is at this age, when the external evidence becomes extremely fragmentary, that new political movements were inaugurated and new confederations of states sprang into existence. Palestine had been politically part of Egypt or of the Hittite Empire; we now reach the stage where it becomes more closely identified with Israelite history.

Palestine had not as yet been absorbed by any of the great powers with whose history and culture it had been so closely bound up for so many centuries. In the “Amarna” age the little kings had a certain measure of independence, provided they guarded the royal caravan routes, paid tribute, refrained from conspiracy, and generally supported their overlords at their ages. However profound the influence of Babylonian and Sumerian training, excavation has discovered comparatively few specific traces of it. Although cuneiform was used, the Palestinian letters show that the native language, as in the case of earlier proper-names, was most nearly akin to the later “Canaanite” (Hebrew, Moabite and Phoenician). In view of the relations subsisting among Palestine, Mittanni and the Hittites, it is evident that Babylonian

influence could have entered indirectly; and until one can determine how much is specifically Babylonian the analogies and parallels cannot be made the ground for sweeping assertions. The influence of a superior power upon the culture of a people cannot of course be denied; but history proves that it depends upon the resemblance between the two peoples and their respective levels of thought, and that it is not necessarily either deep or lasting. A better case might be made for Egypt; yet, not notwithstanding the presence of its colonies, the cult of its gods, the erection of temples or shrines, and the numerous traces of intercourse exposed by excavation, Palestine was Asiatic rather than Egyptian. Indeed Asiatic influence made itself felt in Egypt before the Hyksos age, and later, and more strongly, during the XVIIIth and following Dynasties, and deities of Syro-Palestinian fame (Resheph, Baal, Anath, the Baalath of Byblos, Kadesh, Astarte) found a hospitable welcome. On the whole, there was everywhere a common foundation of culture and thought, with local, tribal elements. The petty kings extracted the similarity of religious phraseology throughout the Semitic sources, and its similarity with the ideas in the Egyptian texts. This makes it more instructive when comparison is made between cuneiform or Egyptian sources extending over many centuries and particular groups of evidence (Amarna letters, Canaanite and Aramaean inscriptions, the Old Testament and later Jewish literature to the Talmud), and pursued to the customs and beliefs of the same area to-day. The result is to emphasize (a) the inveterate and indissoluble connexion between religious, social and political life, (b) the differences between the ordinary current religious conceptions and specific positive developments of them, and (c) the vicissitudes of these particular growths in their relation to history.

There is reason to believe that the religion of Palestine in the Amarna age was not irreligious or inarticulate belief; like the material culture it had passed through the developmental stages and was a fully established though not, perhaps, a very advanced organism. There were doubtless then, as later, numerous local deities, closely connected with local districts, differing perhaps in name, but the centre of similar ideas as regards their relations to their worshippers. Commercial and political intercourse had also brought a knowledge of other deities, who were worth venerating, or who were the survivors of a former supremacy, or whose recognition was enforced. It is particularly interesting to find in the Amarna letters that the supremacy of Egypt meant also that of the national god, and the loyal Palestinian kings acknowledge that their land belonged to Egypt’s king and god. In accordance with what is now known to be a very widespread belief, the king was a semi-divine function, and the Pharaoh was the incarnation of Amon-Re. This would bring a greater coherence of worship among the chaos of local cults. People naturally recognize the identity of the Pharaoh, and they hail him as their god and identify him with the heads of their own pantheon. Thus he is called—in the cuneiform letters—their Shamash or their Addu. The former, the sun-deity, god of justice, &c., was already well known, to judge from Palestinian place-names (Beth-Shemesh, &c.). The latter, storm or weather god, or, in another aspect, god of rain and therefore of fertility, is specifically West Asiatic, and may be equated with Hadad and Ramman (see below). He is presumably the Baal who is associated with thunder and lightning, and with the bull, and who was familiar to the Egyptians of the XIXth and XXth Dynasties in the adulations of their divine king. He is probably also “the lord of the gods” (the head of a pantheon) invoked in a private cuneiform tablet unearthed at Taanach. Besides these gods, and others whose fame may be inferred (Dagon, Nebo, Nergal, &c.), there were the closely-related goddesses Ashira and Ishtar-Astarte (the Old Testament Asherah and Ashtoreth). Possibly the name Yahweh (see JEROVAN) had already entered Palestine, but it is not prominent, and if, as in the case of certain other deities, the extension of the name and cult went hand-in-hand with political circumstances, these must be sought in the problems of the Hebrew monarchy. At an age when there were no great external empires to control Palestine the Hebrew monarchy arose and claimed a premier place amid its neighbours (c. 1000). How the small rival districts with their petty kings were united into a kingdom under a single head is a disputed question; the stages from the half-Hittite, half-Egyptian land to the independent Hebrew state with its national god are an unsolved problem. Biblical tradition quite plausibly represents a mighty invasion of tribes who had come from Southern Palestine and Northern Arabia (Elath, Ezion-geber)—but primarily from Egypt—and after a series of national “judges,” established the kingdom. But no place can be found for this event, as it is described, either before the “Amarna” age (the date, following 1 Kings vi. 1) or about the time of Rameses II. and Mineptah (see Exod. i. 11); and if the latter king (c. 1244) records the subjugation of the people (? or land) “Israel,” the complicated history of names does not guarantee the absolute identity of this “Israel” either with the pure Israelite tribes which invaded the land or with the intermixed people after this event (see JEWs: §§ 6–8). Whatever may have been the extent of this invasion and the sequel, the rise and persistence of an independent Palestinian kingdom was an event which concerned the neighbouring states. Its stability and the necessary furtherance of commerce, usual among Oriental kings, depended upon the attitude of the maritime coast (Philistia and Phoenicia), Edom, Moab, Ammon, Gilead and the Syrian states; and the biblical and external records for the next four centuries (to 586) frequently demonstrate the fact that this is the foundation of many of the interrelations of these states. The evidence of the course of these crucial years is unusual and often sadly fragmentary, and is more conveniently noticed in connexion with the biblical history (see JEWs: §§ 9–17). A conspicuous feature is the difficulty of maintaining this single monarchy, which, however it originated, speedily became two rival states (Judah and Israel). These are separated by a very ambiguous frontier, and have their geographical and political links to the south and north respectively. The balance of power moves now to Israel and now to Judah, and tendencies to internal disintegration are illustrated by the dynastic changes in Israel and by the revolts and intrigues in both states. As the power of the surrounding empires revived, these entered again into Palestinian history. As regards Egypt, apart from a few references in biblical history (e.g., to its interference in Philistia and friendliness to Judah, see PHILISTINE), the chief object of the great invasion by Sheshonk (Shishak) in the latter part of the 10th century was, but after this it appears to be an isolated campaign, contact with Egypt, to judge from the archaeological results of the excavations, was never intermittent. The next definite stage is the dynasty of the Israelite Omri (q.v.), to whom is ascribed the founding of the city of Samaria. The dynasty lasted nearly half a century, and is contemporary with the expansion of Phoenicia, and presumably therefore with some prominence of the south maritime coast. The royal houses of Phoenicia, Israel and Judah were united by intermarriage, and the last two by joint undertakings in trade and war (note also 1 Kings ix. 26 sq.). Meanwhile Assyria was gradually establishing itself westwards, and a remarkable confrontation of the empires of the old Hittite kingdom, “kings of the land of Hatti” (the Assyrian term for the Hittites) was formed to oppose it. Southern Asia Minor, Phoenicia, Ammon, the Syrian Desert and Israel under Omri’s son “Ahab the Israelite” sent their troops to support Damascus, which, in spite of the repeated efforts of tendency to identify them—was perhaps known in Palestine, as it certainly was in Egypt and among the Hittites.

Approach of Assyria.

Shalmaneser,1 was evidently able to hold its own from 854 to 839. The anti-Assyrian alliance was, as often in west Asia, a temporary one, and the inveterate rivalries of the small states are illustrated, in a striking manner, in the downfall of Omri's dynasty and the rise of that of Jehu (842-745); in the bitter onslaughts of Damascus upon Israel, leading nearly to its annihilation; in an unsuccessful attack upon the king of Hamath by Damascus, Cilicia and small states in north Syria; in an Israeliite expedition against Judah and Jerusalem (2 Kings xiv. 13 seq.); and finally in the recovery and extension of Assyrian power—perhaps to Damascus—under Jeroboam II.

In such vicissitudes as these Palestinian history proceeds upon a much larger scale than the national biblical records relate, and the external evidence is of the greatest importance for the light it throws upon the varying situations. Syria could control the situation, and it in turn was influenced by the ambitions of Assyria. Notable alliances are recorded between it and Judah by mutual suspicion and hostility. It is possible, too, that, as the states did not scruple to take advantage of the difficulties of their rivals, Assyria played a more prominent part in keeping these jealousies alive than the evidence actually states. Moreover, in the light of these moves and counter-moves one must interpret the isolated or incomplete narratives of Hebrew history.2 The repeated blows of Assyria did not prevent the necessity of future expeditions, and later, Adad-Nirari III. (812-783) claims as tributary the land of Hatti, Amor, Tyre, Sidon, ‘the land of Omri’ (Israel), Edom and Philistia. Israel at the death of Jeroboam was rent by divided factions, whereas Judah (under Uzziah) has now become a powerful kingdom, controlling both Philistia and the Edomite port of Elath on the gulf of Akaba. The dependence of Judaean sovereignty upon these districts was inevitable; the resources of Jerusalem obviously did not rely upon the small district of Judah alone. If Ammon also was tributary (2 Chron. xxvi. 8), deals with Israel and perhaps Damascus could probably be inferred.

A new period begins with Tiglath-Pileser IV. (745-728): prof- and anti-Assyrian parties now make themselves felt, and when north Syria was taken in 738, Tyre, Sidon, Damascus (under Rezin), ‘Samaria’ (under Menahem) and a queen of Arbel were among the tributaries. It is possible that Judah (under Uzziah and Jotham) had come to an understanding with Assyria; at all events Ahaz was at once encircled by fierce attacks, and was only saved by Tiglath-Pileser's campaign against Philistia, north Israel and Damascus. With the siege and fall of Damascus (733-32) Assyria gained the north, and its supremacy was recognized by the tributaries of north desert and Arabia (Arabi, Tema, Sheba). In 732 Samaria, though under an Assyrian vassal ( Hoshea the last king), joined with Philistia in revolt; in 720 it was allied with Gaza and Damascus, and the persistence of unrest is evident when Sargon in 715 found it necessary to transport into Samaria various peoples of the desert. Judah itself was next involved in an anti-Assyrian league (with Edom, Moab and Philistia), but apparently submitted in time; nevertheless a decade later (701), after the change of dynasty in Assyria, it participated in a great but unsuccessful effort from Phoenicia to Philistia to shake off the yoke, and suffered disastrously.3 With the crushing blows upon Syria and Samaria the centre of interest moves southwards and the history is influenced by Assyria's rival Babylonia (under Marduk-baladon and his successors), by north Arabia and by Egypt. Henceforth there is little Samarian history, and of Judah, for nearly a century and a half, nothing is recorded. Judah was under Assyrian supremacy, and, although it was involved with Arabians in the revolt planned by Babylonia (against Assurbanipal), it appears to have been generally quiescent.

At this stage disturbances, now by Aramaean tribes, now by Arabia, combine with the new rise of Egypt and the weakness of Assyria to mark a turning-point in the world's history. Psammeticus (Psamtik) I. (663-609) with his Greeks, Carians, Ionians and soldiers from Palestine and Syria, re-established once more an Egyptian Empire, and replaced the fluctuating relations between Palestine and the small dynasties of the Delta by a settled policy. Trading intercommunication in the Levant and the constant passage to and fro of merchants brought Egypt to the front, and, in an age of archaic revival, the effort was made to re-establish the ancient supremacy over Palestine and Syria. The precise meaning of these changes for Palestinian history and life can only incompletely be perceived, and even the significance of the great event and of the greater movements with which it was connected is uncertain (see Syrian). At all events, Egypt (under Necho, 669-593) prepared to take advantage of the decay of Assyria, and marched into Asia. Judah (under Josiah) was overthrown at Megiddo, where about nine centuries previously the victory of Tethmosis (Thutmose) III. had made Egypt supreme over Palestine and Syria. But Egypt was now at once confronted by the Neo-Babylonian or Chaldean Empire (under Nabopolassar), which, after annihilating Assyria with the help of the Medians, naturally claimed a right to the Mediterranean coast-lands. The defeat of Necho by Nebuchadnezzar at Carchemish (605) is one of the world-famous battles. Although Syria and Palestine now became Babylonian, this revival of the Egyptian Empire aroused hopes in Judah of deliverance and led to revolts (under Jehoiachin and Zedekiah), in which Judah was apparently not alone.4 They culminated in the fall of this kingdom in 586. Henceforth the history of Palestine is disconnected and fragmentary, and the few known events of political importance are isolated and can be supplemented only by inferences from the movements of Egypt, Philistia or Phoenicia, or from the Old Testament. According to the Chaldean Nabonidus (553) all the kings from Gaza to the Euphrates assisted in his buildings, and the Chaldean policy generally appears to have been favourable towards faithful vassals. Cyrus meanwhile was rising to lead the Persians against Media. After a career of success he captured Babylon (539) and forthwith claimed, in his famous inscription, the submission of Amor. For the next 200 years Palestine remained part of the new Persian Empire which, with all its ramifications on land and sea, embraced the civilized world from the Himalayas to the Euphrates. (Great Rev. xxv. 39.)

Very gradually the face of history underwent a complete change. Egypt had resumed its earlier connexion with the Levantine heirs of the ancient Aegeans, the old empires of the Near East had practically extinguished themselves, and Palestine passed into the fresh life and thought of the Greeks. (See below, p. 617.)

In any consideration of the internal conditions in Palestine it must be observed that there is a continuity of thought, custom and culture which is independent of political changes and vicissitudes of names. With the establishment of an independent monarchy Palestine did not enter into a new world. Whatever internal changes ensued between the "Amarna" age and 1000 B.C., they have not left their mark upon the course of culture illustrated by the excavations. These still indicate communication with Egypt and the north (Syria, Asia Minor; Assyria and the Levant not yet the advent of Greeks), and, more especially, as in certain graves at Gezer, the affinities are with Cyprus and Asia Minor (Caria) of about the 11th or 10th century.5 The use of

1 Recently found to be the third of that name (H. W. Hogg, The Interpreter, 1910, p. 329).
2 See e.g. in references to Ammon, Damascus and Hamath, and in Judaean relations with Philistia, Moab and Edom.
3 Recently published inscription of Senacherib (of 644 B.C.) mentions enslaved peoples from Philistia and Tyre, but does not name Judah.
4 Cf. Jer. xxvii. 2 seq., and the history of the Egyptian Hophra (Apirès, 588-569).
5 At present it is difficult as regards Palestine to distinguish Aegean influence (direct and indirect) from that of Asia Minor generally. Only after the old Cretan (Minoan) culture had passed its zenith and was already decadent does it suddenly appear in Cyprus (H. R. Hall, Proc. Soc. Bibl. Arch. xxxi. 227).
PALESTINE

iron came in about this time, perhaps from the north, and biblical history (I Kings x. 28 seq., see the commentaries) even ascribes to Solomon the import of horses from Kue and Mursi (Cilicia, and Cappadocia). The cuneiform script, which continued in Egypt during the XIXth and XXth Dynasties, was perhaps still used in Palestine; it was doubtless familiar at least at that point during the Assyrian supremacy. But in the meanwhile the “North Semitic” alphabet appears (from 890) with almost identical forms in extreme north Syria (e.g. Sam'al), in Cyprus, Gezer, and in Moab. The type is very closely related to the oldest European (Etruscan) forms, and, in a less degree, to the “South Semitic” (old Minaean and Sabaean); and since it at once begins (c. 700) to develop along separate paths (Canaanite and Aramaean), it may be inferred that the common ancestor was not of long derivation. This alphabet stands in contrast to the old varying types of the Aegean and Asia Minor area and can hardly be of local origin. Under what historical conditions it first appeared is uncertain; and it is a plausible conjecture that once more the north is responsible.1 Too little is known of the north as a factor in Palestinian development to allow hasty inferences, but it is certainly noteworthy, at all events, that the names Amor and Hatti appear to move downstream, and that “Hittite” is applied to Palestine and Philistia by the Assyrians, and to Hebron in the Old Testament, and that Ezekiel (xvi. 3) calls Canaanite Jerusalem the offspring of an Amorite and a Hittite. It is to be observed, however, that the meaning of geographical and ethnical terms for culture in general must be properly tested—the term “Phoenixian” is a conspicuous case in point. Thus, in north Syria the art has Assyrian and Hittite affinities, but is provincial and sometimes rough. Some of the personal names are foreign and find analogues in Asia Minor; but even as the Philistines appear in biblical history as a “Semitic” people, so inscriptions from south Syria (c. 800-700) are in Canaanite and early Aramaean dialects, and are in entire agreement with “Semitic” thought and ideas. The deities too generally bear familiar names. In Sam'al the kings Panammu and Q-ri have non-Semitic names (Carian), but the gods include

The Gods. Hadad, El (God par excellence), Resheph and the Sun-deity. In Hamath we meet with the Baal of Heaven, Sun and Moon deities, gods of heaven and earth, and others. A god “Most High” (ēlōn) was perhaps already known in Hamath.2 The “Baal of Heaven,” reminiscent of the Egyptian title “lord of heaven,” given long before to Resheph, appears in the pantheon of Tyre (c. 677). The reference here is probably to the inveterate Hadad who, in his Aramaean form Ramman (Rimmon), is found in Palestine. Among the Hebrews, Yahweh, some of whose features associate him with thunder, lightning and storm, and with the gifts of the earth, has now become the national god, like the Moabitic Chemosh or the Ammonite Milcom (see Edom, and note also the Moabite stone). Yahweh is the name in the form Ya'ū in north Syria (8th century), and, so far as the Israelite kings are concerned, appears first in the family of Ahab. No images of Yahweh or of earlier Canaanite deities have been unearthed; but images belong to a relatively advanced stage in the development of religion, and the aniconic stage may be represented by the sacred pillars and posts, by the small models of heads of bulls, and by the evidence for calf-cults in the Old Testament.3 Yahweh was by no means the only god. Interests and alliance introduced the cults of Chemosh, Milcom, the Baal of Tyre and the Astarte of Sidon. Excavation has brought to light figurines of the Egyptian Osiris, Isis, Ptah, Anubis and especially Bes. Assyrian conquest and domination influenced the cults at all events outside Judah and Israel, and when Sargon sent skilled men to teach “the fear of God and the king” (cyl. inscr. 72-74) the spread of Assyrian religious ideas among the Hebrews themselves is to be expected. Certainly about 600 the Queen of Heaven, who has Assyrian traits, was a favourite object of veneration (Jer. vii. 18, xlv. 17-19, 25); yet already a century earlier the goddess “Ishtar of heaven” was worshipped by a desert tribe (see Ishmael), and the titles “lady of heaven,” “bride of the king of heaven,” had been applied centuries before to west Asiatic goddesses (Anath, Kadesh, Ashira, &c.). Although no goddess is associated with the national god Yahweh, female deities abounded, as is amply shown by the numerous plaques of the great mother-goddess which have been found in course of excavation. The picture which the evidence furnishes is as fundamental for our conception of Palestine during the monarchical as were the Amarna tablets for the age before they arose. The external evidence does not point to any intervening hiatus and the archaeological data from the excavations do not reveal any dislocation of earlier conditions; earlier forms have simply developed and the evolution is a progressive one. Down to and at the time of the Assyrian supremacy, Palestine in religion and history was merely part of the greater area of mingled peoples sharing the same characteristics of custom and belief. This does not mean of course that the religion had no ethical traits—ethical motives are frequently found in the old Oriental religions—but they were bound up with certain naturalistic conceptions of the relation between deities and men, and, herein lay their weakness.4

In the age of the Assyrian supremacy Palestine entered upon a series of changes, lasting for about three centuries (from about 700 to 674), which were of course a part of the phenomena of the internal development of Syria. The swelling conquests of Assyria were “as critical for religious as for civil history.”5 The brutal methods of warfare, the cruel treatment of vanquished districts or cities, and the redistribution of bodies of inhabitants, broke the old bonds uniting deities, people and land. The framework of society was shattered, communal life and religion were disorganized. As the flood poured over Syria and flowed south, Israel (Samaria) suffered grievously, and the gaps caused by war and deportation were filled up by the introduction of new settlers by Sargon, and by his successors in the 7th century. Unfortunately, there is very little evidence in the biblical history for the subsequent career of Samaria, but it is clear that the old Israel of the dynasties of Omri and Jehu received crushing blows. The fact that among the new settlers were desert tribes, suggests the introduction of a new religion, of a simpler culture, but also of simpler groups of ideas. In the nature of the case 79 as time elapsed the new population must have taken root as securely as—one must conclude—the invading Israelites had done some centuries earlier. As a matter of fact the prophets Jeremiah and Ezekiel by no means regarded the population lying to the north of Judah as strangers, and the latter in turn were ready to share the Judean distress at the fall of Jerusalem (Jer. xli. 5), and in later years offered to assist in rebuilding Yahweh's temple. Indeed, since the Samaritans subsequently accepted the Pentateuch, and claimed to inherit the ancestral traditions of the Israelite tribes, it is of no little value in the study of Palestinian history to observe the manner in which this people of singularly mixed origin so thoroughly assimilated itself to the land and at first was virtually a Jewish sect. But Samaria was not the only land to suffer. Judah, towards the close of the 8th century, was obviously very closely bound up with Philistia, Edom and Egypt; and this and Hezekiah's dealings with the anti-Assyrian party at Ekron do not indicate that any feeling of national exclusiveness, or any abhorrence of the

2 Dörpfeld introduces the place-name Urf(light) of hi-še-en (Ras Bello, see Edom, and note also the Moabite stone). This is Calf, Golden, and note the representation of a calf in Ramman (Ramman = Hadad) in east Jordan (Gressmann, p. 33). It is obvious that the strict injunctions in Exod. xx. 4. Deut. xxv. 3, 23, 26, and other references to idolatry, are the outcome of a reaction against images.

3 See G. F. Dictionnaire, and note the representation of a calf at er-Rummân (Ramman = Hadad) in east Jordan (Gressmann, p. 33). It is obvious that the strict injunctions in Exod. xx. 4. Deut. xxv. 3, 23, 26, and other references to idolatry, are the outcome of a reaction against images.

5 Ibid. p. 35; cf. pp. 65, 77 sqq., 358.
“uncircumcised Philistines” predominated. From the description of Sennacherib’s invasion it is clear that social and economic conditions must have been seriously, perhaps radically disturbed,1 and the quiescence of Judah during the next few decades implies an internal weakness and a submission to Assyrian supremacy. During the 7th century new movements were coming from Arabia, and tribes growing ever more restless made an invasion east of the Jordan through Edom, Moab and Ammon. Although they were repulsed, this awakening of a land which has so often fed Palestine and Syria, when viewed with the increasing weakness of Assyria, and subsequent vicissitudes in the history of the Edomites, Nabataeans and East Jordan tribes, forbids us to treat the invasion as an isolated raid.2 Later, the fall of the Judean kingdom and the deportation of the leading classes brought a new social upheaval. The land was not denuded, and the fact that “some scores of thousands of Jews remained in Judah through all the period of the exile,”3 even though they were “the poorest of the land,” revolutionizes ordinary notions of this period. (See Jews: § 18). But the Judean historians have successfully concealed the course of events, although, as has been recognized, there was some movement upwards from the south of Judah of groups closely related to Edomite and kindred peoples of South Palestine and Northern Arabia. The immigrants, like the new occupants of Samaria, gradually assimilated themselves to the new soil; but the circumstances can hardly be recovered, and even the relations between Judah and Samaria can only be inferred. In the latter part of the 6th century we find some restoration, some revival of the old monarchy in the person of Zerubbabel (530 B.C.); but again the course of events is problematical (Jews, § 20).4 Not until the middle of the 5th century do the biblical records (book of Nehemiah) furnish a foundation for any reconstruction. Here Jerusalem is in some distress and in urgent need of reorganization. Zerubbabel’s age is of the past, and any attempt to revive political aspirations is considered detrimental to the interests of the surrounding peoples and of the Persian Empire. Scattered evidence suggests that the Edomites were responsible for a new catastrophe. Amid internal and external difficulties Nehemiah proceeds to repair religious and social abuses, and there is an important return from Babylonia. The ruling classes are related partly to the southern groups already mentioned and partly to Samaria; but the kingship of old is replaced by a high-priest, and, under the influence of Babylonian Jews of the strictest principles, a breach was made between Judah and Samaria which has never been healed (Jews: § 21 seq.). Biblical history itself recognizes in the times of Artaxerxes, Nehemiah and Ezra the commencement of a new era, and although only too much remains obscure we have in these centuries a series of vicissitudes which separate the old Palestine of Egyptian, Hittite, Babylonian and Assyrian supremacy from the land which was about to enter the circle of Greek and Roman civilization. This division, it may be added, also seems to leave its mark upon the lengthy archaeological history of Palestine from the earliest times to the Byzantine age. There is a certain poverty and decadence of art, a certain simplicity of civilization and a decline in the shape and decoration of pottery which seems to exhibit signs of derivation from similar prototypes elsewhere associated with desert peoples. This phase comes at a stage which severs the earlier phases (including the “Amarna” age) from those which are very closely connected with Seleucid and later times. Its appearance has been associated with the invasion of the Israelites or with the establishment of the independent monarchy, but on very inadequate grounds; and since it has been independently placed at the latter part of the monarchy, its historical explanation may presumably be found in that break in the career of Palestine when peoples were changed and new organizations slowly grew up.5 The great significance of these vicissitudes for the course of internal conditions in Palestine is evident when it is observed that the subsequent cleavage between Judah and Sámaria, not earlier than the 5th century, presupposes an antecedent common foundation which, in view of the history of the monarchies, can hardly be earlier than the 7th century. These centuries represent an age which the Jewish historians have partly ignored (as regards Sámaria) and partly obscured (as regards the return from exile and the reconstruction of Judah); but since this age stands at the head of an historical development which leads on to Christianity and Rabbinical Judaism, it is necessary to turn from Palestine as a land in order to notice more particularly certain features of the Old Testament upon which it is based.

The Old Testament is essentially a Palestinian, an Oriental, work and is entirely in accord with Oriental thought and custom.6 Yet, in its characteristic religion and legislation there are essential spiritual and ethical peculiarities which give it a uniqueness and a permanent value, the reality of which becomes more impressive when the Old Testament is viewed, not merely from a Christian or a Jewish teleology, but in the light of ancient, medieval and modern Palestine. The ideas which characterize the Old Testament are planted upon lower levels of thought, and they appear in different aspects (legal, prophetic, historical) and with certain developments both within its pages and in subsequent literature. To ignore or to obscure the features which are opposed to these ideas would be to ignore the witness of external evidence and to obscure the old Testament itself. The books were compiled and preserved for definite aims, and their teaching is directed now to the needs of the people as a whole—as in the ever popular stories of Genesis—now to the incultation of the lessons of the past, and now to matters of ritual. They are addressed to a people whose mental processes and philosophy were primitive; and since teaching, in order to be communicable, must adapt itself to current beliefs of God, man and nature—and the invertebrate conservatism of man must be born in mind—the trend of ideas must not be confused with the average standard of thought.7 The teaching was not necessarily presented in the form of an over-elaborated moral lesson, but was associated with conceptions familiar to the land; and when these conceptions are examined from the anthropological standpoint, they are found to contain much that is strange and even abhorrent to modern convictions of a purely spiritual deity. There are moreover many traces of conflicting ideas and ideals, of cruder beliefs and customs, and of attempts to remove or elevate them. In Genesis and elsewhere there are examples of popular thought which have not the characteristic spirit of the prophets, and which, it is clear, could only gradually be purified. The notion of a Yahweh scarcely less powerful than man, the naive, yet superhuman beings and their nearness to man, and the persistence of features which stand relatively low in the scale of mental culture, only serve to enhance the reality of the spirit which inspired the endeavour to reform. There were rites and customs which only after lapse of time were considered iniquitous. Magical practices and forms of sacred prostitution and human sacrifice were familiar, and the denunciations of the prophets and the

1 See G. A. Smith, Jerusalem, ii. 160, 196 seq. 2 See L. E.坚定不. Israel, Jour. Roy. Soc. and Pal. (London, 1902), p. 269; Winckler, Keittinschr., v. 513. 3 G. A. Smith, Jerusalem, ii. 269. 4 On ordinary historical grounds it is probable that there was a political reorganization in the divergent results of the land (J. A. Montgomery, The Samaritans, Philadel- phia, 1907; p. 62 seq.). There is internal literary support for this in the criticism of Deuteronomy (which appears to have in view a comprehensive Israel and Judah at this period), and of various passages evidently earlier than Nehemiah’s time (see R. H. Kennett, Journ. of Theol. Stud., 1905, pp. 175–181; 1906, pp. 486, 498). 5 For the late date, see F. Petrie, Tell-el-Hesi (1891), p. 47 seq., and Bliss and Macalister, Excavations in Palestine (1902), pp. 72, 74, 101, 124, and, for the suggestion in the text, S. A. Cook, Expositor, (Aug. 1909), pp. 104–114. 6 See, e.g., E. Sellin, Aller. Relig. im Rahmen der anden alteroriental- ischen (Leipzig, 1908). 7 On the characteristics of primitive thought, see G. F. Stout, Manual of Psychology (London, 1907), Bk. IV, especially pp. 574–579.
lawgivers show very vividly the persistence of what was current religion but was hostile to their teaching.¹ There is an astonishing boisterousness (cf. Lam. ii. 7), joviality and sensuality, all in striking contrast to the austerity of nomad asceticism. There is a ferocity and fanaticism which manifests itself in the belief that war was a sacred campaign of deity against deity. Even if the account of the “ban” (utter destruction) at the Israelite conquest be unhistorical, it represents current ideas (cf. Josh. vi. 17 seq.; 1 Sam. xv. 3; 2 Kings xv. 16; 2 Chron. xxiv. 17 seq.), and implies imperfect views of the Godhead at a more advanced stage of religion and morality.

There are conflicting ideas of death and the dead, and among them the belief in the very human feelings and needs of the dead and in their influence for good or evil.² Moreover, the proximity of burial-place and sanctuary and the belief in the kindly care of the famous dead for their descendants reflect “primitive” and persisting ideas which find their parallel in the holy tombs of religious or secular heroes in modern Palestine, and exemplify the firmness of the link uniting local groups with local suumens.³

“The permanence of religion at holy places in the East” is one of the most important features in the relation between popular and national religion. The local centres will survive political and historical vicissitudes and the changes of national cults and sects, and may outlive the national deities. The supernatural beings may change their name and may vary externally under Greek, Roman, Mahomedan or Christian influence; but their relation to the local groups remains essentially the same, although there is no regression to earlier organic connexions. The inveterate local, one may perhaps say immediate, powers are felt to be nearer at hand than the national deity, who is more closely bound up with the changing national fortunes and with current philosophy. These smaller deities are, as it were, telluric, and the territory of each is virtually heathenistic—as also its traditions—and even as to-day the saints or “idols” of the common people, so were also the ancient people.⁴

H. Geering suggests that the Samarian religion was perhaps of Median origin (Meyer § 345), and as a preliminary to marriage seems to have been known not only in Assiya (Herod. i. 199), but also in Palestine (“a law of the Amorites”—Test. of Judah, ed. R. H. Charles, 334; 2 Kings iii. 4 sqq.; Jer. xxxiii. 18 sqq.; E. B. Tylor, Oxford, 1907), pp. 189-202. (For miscellaneous literature see J. G. Frazer, ibid. pp. 101-174: “Folk-lore in the Old Testament.”)

² See generally E. Meyer, Gesch. d. Altertum’s (Berlin, 1890), i. §§ 342 sqq. Governmental deism was perhaps of Median origin (Meyer § 345), and as a preliminary to marriage seems to have been known not only in Assiya (Herod. i. 199), but also in Palestine (“a law of the Amorites”—Test. of Judah, ed. R. H. Charles, 334). The authors of the Septuagint, which is not a Hebrew book, but a Greek translation, and the authors of the Testament of Judah, who lived about the middle of the 2d century B.C., are both interested in the tradition of the old Babylonian and Phoenician nationalism.

³ The title of the instructive essay by Sir W. M. Ramsay in the Expositor, Nov. 1906, pp. 454 sqq. The whole subject involves also the various developments of the old traditions, of which the chief is, cf. E. Lucas, Anfänge des Heiligenkultus, etc. (Tübingen, 1904), P. Saintyves, Saints successeurs de dieu (Paris, 1907).

⁴ On the old Baals of Palestine, see H. P. Smith, in O. T. and Semitic Religion, etc. (Philadelphia, 1886), pp. 33-56. For the persistence of the “high places,” see G. F. Moore, Phil. bibl. arts. “High Place,” “Idolatry and Primitive Religion.”

⁶ The shrines of the Chaldeans, Molosses, Baal of Tyre and Ashtar of Sidon (1 Kings xi. 1-8; 2 Kings xi. 18, xxiii.); the valley of Hinom (see J. A. Montgomery, Journ. Bibl. Lit., xxiv. i. 24-47); and the place-names Anthoth (Anthath), Nob (Noboth), Beth-ninith, Beth-shemesh. The name Jerusalem may be compounded with the main line of intercourse and one may look for a certain conservatism in its famous Temple. Temples, shrines and holy places were no novelty in Palestine, and the inauguration of the great centre of Judaism is ascribed to Solomon the son of the great conqueror David.

Phoenician aid was enlisted to build it, and the Egyptian analogies to the construction accord with the known influence of Egypt upon Phoenician art. It is the dwelling-place of the deity, the centre of the nation and of the national hopes; the fall of the Temple follows after Yahweh left it, it is rebuilt and he returns (Zeck. vii. 3). The Temple is merely part of the royal palace and the government buildings (cf. Ezek. xliii. 7 seq.), and it is as significant as the king’s position in its management. It is in keeping with the old conceptions of the divine kingship, which, though they survive only in isolated biblical references, live on in the ideals of the Messianic king and his kingdom and in the post-exilic high priest.⁷

When the Temple was built, ornamented and furnished, the shrines and temples of the famous deities are quite incompatible with a spiritual religion. Mythical features abound in the cherubim and seraphim, the pillars of Jachin and Boaz, the mysterious Nehustan, the bronze-sea and the lavers. These agree with the more or less clear allusions in the Old Testament to myths of creation, Eden, deluge, mountain of gods, Titanic folk, world-dragons, heavenly hosts, etc., and also with the unearthed seals, tablets, etc. representing mythical ideas. The ideas occur in varying forms from Egypt to Babylonia and point to a considerable body of thought, which is not less impressive when one takes into account the instances in the Old Testament where myths have been rationalized, elevated, or otherwise removed from their original forms (e.g. the story of the birth of Moses, accounts of creation and deluge, etc.), or when one observes the subsequent uncompromising objection to a display of artistic meaning, implying that it aroused definite conceptions. To reinterpret all these features as mere symbols, the number of ancient days, it is to avoid the problem of their introduction into the Temple, and to assume an advance of popular thought which is not confirmed by the retention and fresh developments of the old ideas both in the pseudographical literature and in the literature of Rabbinical Judaism.⁸

The horses of the sun-god (Z 1 Kings xliii. 11), too, belong to a group of ideas which may perhaps be associated with the plan of the Temple and with the old hymn of dedication (1 Kings viii. 12 seq.). At all events, when one considers the Babylonian-Assyrian conceptions of Shamash as the supreme and righteous judge, god of truth and justice, or the monotheism of Amnon and the famous idea of the sun-god, it is certain that a corresponding Palestinian deity would not necessarily be without ethical and elevated associations.⁹ In short, the place which the Temple held in that of a deity (Winckler, Keil. u. A. T. 224 seq.; G. A. Smith, Jerusalem, ii. 25 seq.), and the deity of the temple was curiously associated with many other names of the Jerusalem priests Zadok, Jehozadak, etc. (cf. M. Zedek, Jerusalem, gen. xiv.), and the kings Adonizek and Zedekiah. The strange character of the names of the first kings in Israel and Judah (Salv, David and Solomon), noticed already by Miiller (Modern Review, 1884, pp. 158-169), cannot easily be explained.

¹ See A. B. Davidson, H. C. Davidson, H. C. Davidson, Theod. of O. T. (Edinburgh, 1904), p. 9; J. G. Frazer, Adonis, Attis and Osiris (London, 1907), pp. 12 sqq. In general the idea of the “Angel of Yahweh,” the simile “as a messenger (of) Yahweh” (2 Sam. vii. 16) and the idea of the king as the embodiment of his people’s safety (2 Sam. xxii. 17; Lam. iv. 20), and the absence of the delimitation of the character of the priestly religious which recognizes Yahweh as the only king (cf. J. G. Frazer, Einführung in die ursprüng. d. israelit. Rel. Eschatologie (Göttingen, 1905), pp. 250 sqq.

³ For examples of the persistence of the interrelated ideas—whether of a central significance or not is another question—see A. Jeremias, Babylon in the Psalter (Leipzig, 1905), pp. 126 sqq.; Lichte d. Alter Orientis (1906); E. Bicher, Bab. Astrales im Weltbild d. Thaism und d. Midrash (1907).

⁹ See for an excellent example of Oriental religious thought, the famous Babylonian hymn to Ishtar (i.e. Astarte) L. W. King, Sacred Tables of Creation (London, 1907), pp. 222-237, and the specimens in R. W. Rogers, Rel. of Bab. and Ass. in its Relations to Israel (London, 1908), pp. 142-184. On ethical conceptions of heathen deities see J. King, Development of Religion (New York, 1910), pp. 268-286.
religious thought (cf. especially Isaiah), the character of the reforms ascribed to Josiah (2 Kings xxiii.), the pictures drawn by Jeremiah and Ezekiel, and the latter's condemnation of the half-Hittite, half-Amorite capital, combine with the events of later history to prove that the religion of the national sanctuary must not be too narrowly estimated from the denunciations of more spiritual minds or from a priori views of the inevitable concomitants of either henotheism or monothelism or of a lofty ethical teaching.

There is indeed a development, but it is none the less noteworthy that the post-exilic priestly ritual preserves in the worship of the universal and only God Yahweh, rites, practices and ideas which can be understood only in the light of other nature-religions, especially that of Babylonia, with which there are striking parallels. For example, the ephod, an object of divination, is still retained, but it is now restricted to the high-priest; and his position as head of a theocratic state, and his ceremonial dress with its heathenish associations presuppose a past monarchic. Clad in almost barbaric splendour (cf. Eccles. xvi. 1, and Jos. Ant. iii. 7, &c.), he reproduces the glory of the worshipping body like the king of old, and sometimes plays as important a part in the later political history. The priestly system, as represented in the Pentateuch, is not fitted for the desert, where its initiation is ascribed, but on independent internal critical grounds belongs to the post-exilic age, where it stands at the head of further developments. It is the adaptation of the prophets' conceptions of Yahweh to old religious ideas, the building up of new conceptions upon an old basis, a fusion "between old heathen notions and prophetic ideas," and "this fusion is characteristic of the entire priestly law." The priestly religion bound together the community in a way that alone preserved Jewish monothelism; it stands at the head of a long, unintermittent history, and it is to be viewed, not so much as the climax of Old Testament religion, but as one of a series of inseparable stages. In concentrating the religious observances of the people upon Jerusalem, its Temple and its priesthood, it became less spontaneous, and its services more remote from ordinary life. It left room for rival schools and sects, both within and without the priestly circles, and for continued development of the older and non-priestly thought. These reacted upon this institutional religion, which readapted and reinterpretated itself from time to time, and when they did not help to build up another theology (as in Christianity), they ended by assuming too rigid and unprogressive a shape (see QARITES), or, breaking away from long-tried convention, became a mysticism with mixed results (see KABBALAH). While these vicissitudes take us away from Palestine, the course of native religious thought is very significant for its relation to the earlier stages. Although the national God was at once a transcendent ruler of the universe and also near at hand to man, the unconscious religious feeling found an outlet, not only in the splendid worship at Jerusalem, but in the more immediate intercessors, divine agencies, and the like; and when Judaism left its native soil the local supernatural beings revived, and, superimposed on the old, new shapes found their place off their Greek dress—and they still survive, under a veneer of Mahommemanism, as the modern representatives of the Baals of the distant past.  

The presence of parallels also in South Arabian and Phoenician cults suggests that the old Palestinian ritual was in general agreement with the Oriental religions. Specific influence on the part of Babylonia is not excluded; but the absence of striking points of agreement in other portions of the Old Testament may not be due to the absence of an influence altogether, but simply to the particular character of the circles to which they belonged.  

3 C. Montefiore, in the Hibbert Lectures, 1892, p. 320, cf. p. 322 ("[the] marriage of heathen practice and monotheistic use is one of the oddest and safest features of the whole priestly code").  

5 The uniqueness of the Old Testament religion is stamped upon the Mosaic legislation, which combines in archaic manner ritual, ethical and civil enactments. As a whole, the economic conditions implied are pastoral and agricultural, and are relatively primitive; and the general rudimentary character of the legal ideas appears in the death penalty for the going ox (Exod. xxvi. 28), resort to ordeal (Num. v. ii-31), and in the treatment of murder, family, marriage, slaves and property. The use of writing is once contemplated (the "bill of divorce," Deut. xxiv. 3), but not in ordinary business; oaths and symbols are used instead of written contracts, and the commercial law is notably scanty. The simplicity of the legislation is also manifest in the land-system in Lev. xxv., which implies a fresh beginning and not a readjustment of earlier laws. In property succession there is a feeling of tribal aloofness which would not be favourable to a central authority; and in fact the legal machinery is rude, and the carrying out of the law depends not so much upon courts and officials as upon religious considerations. If there is a supreme court, it is priestly (Deut. xvii. 8-13), and its legislation is bound up with the worship of Yahweh, who avenges wrong. This legislation appears as that of the Israelites, newly escaped from bondage in Egypt, joined by an ethical covenant-relationship with Yahweh, and waiting in the desert to enter and conquer the land of their ancestors. But it is remarkable that, although within the Old Testament itself there are certain different backgrounds, important variations and developments of law, these are relatively insignificant when we consider the profound changes from the 15th-13th centuries (apparent by the period of the conquest) to the close of Old Testament history. Yet, the conditions in Palestine during the monarchies reveal grave and complex social problems, marked class distinctions, and constant intercourse and commercial enterprise. There was no place for tribal exclusiveness, and the upkeep of a monarchy (including the Temple) and the occasional payment of tribute would require duly appointed officials and a central body. The priestly laws relating to the worship of the country rather than to personal life (note the picture of feminine luxury in Isa. iii. 16 sqq.; cf. Amos iv. 1-3). In general the priestly legislation as a whole presupposes an undeveloped state of society, and would have been inadequate if not partly obsolete or unintelligible during the monarchies. But more elaborate legal usages had long been known outside Palestine, and, to judge from the Talmud and the Syrian law-code (c. 5th century A.D.), long prevailed. Oriental law is primitive or advanced according to the social conditions, with the result that antiquity of ideas is no criterion of date, and modern desert custom is more archaic than the great code of the Babylonian king Khammurabi (c. 2000 B.C.). Common law is merely part of the national life, and where it is implicated with religion there is no uniformity over an area comprising different groups of people. In such a case there is resort to a controlling authority, whether self-imposed (like the divine Pharaoh of the Amarna age), or mutually agreed (as Mahomet and the Arabian clans). It cannot be definitely said that the old Babylonian code was in force in Palestine. On the other hand, it is known that it was being diligently copied by Assur-bani-pal's scribes (7th century B.C.), and in view of the circumstances of the Assyrian domination, it is probable that, so far as Palestinian economic conditions permitted, a legislation more progressive than the Pentateuch.

Palestin. Bodenlehre in der israel. Relig. (Berlin, 1899), pp. 16 sqq. In the above, and in other respects also, a summary of the history of Palestine suggests the necessity of modifying that "biological" treatment of the development of thought which pays insufficient attention to the persistence of the representatives of different stages or to the disappearance of the higher stages; see I. King, op. cit., pp. 204 sqq.  

7 See W. R. Smith, Rel. of Semites, p. 70, who compares the judicial authority of Moses. Note also the British Indian legislation imposed upon the various castes and creeds and each with their peculiar rites and customs.
(in certain well-defined portions) priestly authority, excludes a monarchy and stands at the head of a lengthy development in the way of expansion and interpretation. Its true place in biblical history has been the problem of generations of scholars, and the discovery (Dec. 1901-Jan. 1902) of the Babylonian code has brought new problems of relationship and of external influences. Although on various grounds there is a strong probability that the code of Khammurabi must have been known in Palestine at some period, the Old Testament does not manifest such traces of the influence as might have been expected. Pentateuchal law is relatively unprogressive, it is marked by a characteristic simplicity, and by a spirit of reform, and the persisting primitive social conditions implied did not harmonize with other internal and external data. The existence of other laws, however, is to be presupposed, and there appear to be cases where the Babylonian code lies in the background. An independent authority concludes that the co-existing likeness and differences argue for an independent recension of ancient custom deeply influenced by Babylonian law. The questions are involved with the reforming spirit in biblical religion and history. On literary-historical grounds the Pentateuch in its present form is post-exilic, posterior to the earlier monarchies and to the ideals of the earlier prophetic writings. The laws are (a) partly contempory collections (chiefly of a ritual and ceremonial character) and (b) partly collections of older and different origin, though now in post-exilic frames. The antiquity of certain principles and details is undeniable—as also in the Talmud—but since one must start from the organic connexions of the composite sources, the problems necessitate proper attention to the relation between the stages in the literary growth (working backwards) and the vicissitudes which culminate in the post-exilic age. The simplicity of the legislation (traditionally associated with Moab and Sinai and with Kadesh in South Palestine), the humanitarian and reforming spirit, the condemnation of abuses and customs are features which, in view of the background and scope of Deuteronomy, can hardly be severed from the internal events which connect Palestine of the Assyrian period with the time of Nebuchadnezzar.  

The introduction, spread and prominence of the name Yahweh, the development of conceptions concerning his nature, his supremacy over other gods and the lofty monotheism which denied a plurality of gods, are questions which, like the biblical legislative ideas, cannot be adequately examined within the narrow compass of the Old Testament alone.  

The biblical history is a "canonical" history which looks back to the patriarchs, the exodus from Egypt, the law-giving and the covenant with Yahweh at Sinai, the conquest of Palestine by the Israelite tribes, the monarchy, the rival kingdoms, the fall and exile of the northern tribes, and, later, of the southern (Judah), and the reconstructions of Judah in the times of Cyrus, Darius and Artaxerxes. It is the first known example of continuous historical writing (Genesis to Kings, Chronicles-Ezra-Nehemiah), and represents a deliberate effort to go back from 1 See BIBLE: Old Test. Criticism; Jews, §§ 16, 23, 24, 1901; J. G. D. Alexander, O. Johnstone, O. C. Whitehouse, Century Bible, on Isa. x. 1 seq.  

two epoch-making events stand out: (a) the rediscovery of the Book of the Law (Deuteronomy is meant) in the time of Josiah (2 Kings xxiii.) followed by a reform of sundry religious abuses dating from the foundation of the temple, and (b) the promulgation by Ezra of the Law of Yahweh, the law of Moses (Ezra vii. 10, 14; Neh. viii. 1), in the age of Nehemiah, at the very close of biblical history. This legislation, endorsing

1 O. C. Whitehouse, Century Bible, on Isa. x. 1 seq.  

the days when the Judeans separated from the Samaritans to the very beginning of the world. A characteristic tone pervades the history, even of the antediluvian age, from the creation of Adam; or rather, the history of the earliest times has been written under its influence. It reveals itself in the days of the Patriarchs, before the "Amarna" age—or rather in the narratives relating to these remote ancestors. It will be perceived that an objective attitude to the subjective writings must be adopted, the starting-point is the writings themselves and not individual preconceptions of the authentic history which they embody. Although there are various points of contact with Palestinian external history, there is a failure to deal with some events of obvious importance, and an emphasis upon others which are less conspicuous in any broad survey of the land. There are numerous conflicting details which unite to prove that various sources have been used, and that the structure of the compilation is a very intricate one, the steps in its growth being extremely obscure. In studying the internal peculiarities and the different circles of thought involved, it is found that they often imply written traditions which have a perspective different from that in which they are now placed. As regards the pre-monarchical period, some evidence points to a settlement "apparently from Aramaean localities) of the patriarchs, and of Israel (Jacob) and his sons, i.e. the "children of Israel." It ignores a sojourn to Egypt and the subsequent invasion. The parallel account in the book of Joshua of the entrance of the "children of Israel" is, in its present form, the sequel to the journey of the people along the east of Edom and Moab after the escape from Egypt, and after a sojourn at Kadesh (Exodus-Deuteronomy). But other evidence also points to an entrance from Kadesh into Judah, and associates the kin of Moses, Kenites, Calebites and others. Thus, the tradition of a residence in Egypt, implied also in the stories of Joseph, has certainly become the "canonical" view, but the recollection was not shared by all the mixed peoples of Palestine; and to this difference of historical background in the traditions must be added divergent traditions of the earlier population. Traditions, oral and written, with widely differing standpoints have been brought together and merged. Moreover, the elaborate account of the vast invasion and conquest, the expulsion, extermination and subjugation of earlier inhabitants, and the occupation of cities and fields, combine to form a picture which cannot be placed in Palestine during the 15th-12th centuries. It must not be denied that the recollection of some invasion may have been greatly identified by later interpreters with the earlier immigrations and internal movements in the 8th-6th centuries, that is to say, immediately preceding the post-exilic age, when this composite account in the Pentateuch and Joshua reached its present form. An enormous gap severs the pre-monarchical period from this age, and while the tribal schemes and tribal traditions can hardly be traced during the monarchies, the inclusion of Judah among the "sons" of Israel would not have originated when Judah and Israel were rival kingdoms. Yet the tribes survive in post-exilic literature and their traditions develop hereinafter in Jubilees, Testament of the XII Patriarchs, &c. During the changes from the 8th century onwards a non-monarchical constitution naturally prevailed, first in the north and then in the south, and while in the north the mingled peoples of Samaria came to regard themselves as Israelite, the southern portion, the tribe of Judah, proves in 1 Chron. ii. & iv. to be largely of half-Edomite blood. A common ground previous to the Samaritan schism is ignored; it is found only in the period before the rival kingdoms. The political history of these

monarchies in the book of Kings is singularly slight considering the extensive body of tradition which may be pre-supposed, e.g. the reigns of Jeroboam II. and Uzziah, or which may be inferred from the evidence for different sources dealing with other periods. The scanty political data in the annalistic notices of the north kingdom are supplemented by more detailed narratives of a few years leading up to the rise of the last dynasty, that of Jehu. The historical problems involved point to a loss of perspective (Jews, § 11), and the particular interest in the stories of Elijah and Elisha in an historical work suggests that the political records passed through the hands of communities whose interest lay in these figures. Old tradition suggests the "schools of the prophets" at Jericho, Gilgal and Bethel, and in fact the proximity of these places, especially Bethel, to Judean soil may be connected with the friendly and sometimes markedly favourable attitude to Judah in these narratives. The rise of the kingdom of Israel under Saul is treated at length, but more prominence is given to the influence of the prophet Samuel; and not only is Saul's history written from a didactic and prophetical standpoint (cf. similarly Ahab), but the great hero and ruler is handled locally as a petty king at Gibeah in Benjamin. The interest of the narratives clings around north Judah and Benjamin, and more attention is given to the rise of the Judean dynasty, the history of Saul, and the romantic friendship between his son Jonathan and the young David of Bethlehem. The history of the northern and southern kingdoms is handled separately in Kings; but in Samuel the rise of each is closely interwoven, and to the greater glory of David. The account of his steps contains details touching Judah and its relation to Israel which cannot be reconciled with certain traditions of Saul and the Ehrnphaitite Joshua. It combines amidst various material a hero of Bethlehem and rival of Saul with the idea of a conqueror of this district; it introduces peculiar traditions of the ark and sanctuary, and it associates David with Hebron, Calebites and the wilderness of Paran. The books of Samuel and Kings have become, in process of compilation, the natural sequel to the preceding books, but the conflicting features and the perplexing differences of standpoint recur elsewhere, and the relationship between them suggests that similar causes have been operative upon the compilation. The history of Judah is, broadly speaking, that of the Davidic dynasty and the Temple, and it begins at the time of the first king of the rival north. Care is taken to record the transference of secular power and of Yahweh's favour from Saul to David, and David begins his reign with the help of a seer, the young David of Bethlehem. The chronicles of Jerusalem are over the idolatrous north and over the "high places" is the main theme, and with it is the supremacy of the native Zadokite priests of Jerusalem over others (e.g. of Shiloh), who are connected with the desert traditions. The political history is relatively slight and uneven, and the framework is rehandled in Chronicles upon more developed lines and from a later ecclesiastical standpoint, which suggests that many traditions of the monarchy were extant in a late dress. Both books represent the same general trend of political events, even where the "canonical representation is most open to criticism. Chronicles, with the book of Ezra and Nehemiah, makes a continuity between the old Judah which fell in 586 and the return (time of Cyrus), the rebuilding of the temple (Darius), and the reorganization associated with Nehemiah and Ezra (Artaxerxes). Historical material after 586 is scanty in the extreme, and, apart from the records of Nehemiah and a few other passages, the interest lies in the religious history of the communities and reformers who returned from Babylonia. The date and composite book of Chronicles places at the head of the Israelite divisions, which ignore the exodus (1 Chron. vii. 1), and the theory that David was of S. Judaeans or S. Palestinian origin (Marquart, Winckler, Cheyne, Ency. Bib. cols. 1020, 2613 seq.), and, also, that he knit together the southern non-Judean clans (see, David, JUDAH). But it is preferable to recognize different traditions of distinct origin and to inquire what genuine elements of history each may contain.

1 In the art. Jews, §§ 1-24, the biblical history is taken as the foundation, and the internal historical difficulties are noticed from stage to stage. In the present state of biblical historical criticism this plan seemed more advisable than any attempt to reconstruct the history; the necessity for some reconstruction will, however, be clear to the reader on the grounds of both the internal intricacies and the external evidence.

2 See, in the first instance, E. Meyer (and B. Luther), Die Israeliter und ihre Nachbarstämme (Halle, 1905); also art. GENESIS.
The history of the Palestine, as well as the official lists, and more especially in the ecclesiastical bodies inaugurated by David, from whose time the supremacy of this Judah is dates. The historical framework contains traditions of the reconstruction and repair of temple and cult, of the hostility of southern peoples and their allies, and of conflicts between king and priests. This respect of the Judean kingdom must be taken with the following books, where the crucial features are (a) the presence (c. 444) of an aristocracy, partly (at all events) of half-Edomite affinity, before the return of any important body of exiles (Neh. iii); (b) the gaps in the history between the fall of Samaria (722) and Jerusalem (586) to the rise of the hierocracy, and (c) the relation between the hints of renewed political activity in Zerubbabel's time, when the Temple was rebuilt (c. 520-516), and the mysterious catastrophe (with perhaps another disaster to the Temple), probably due to Edom, which is implied in the book of Nehemiah (c. 444). (See Jews, § 22.) These data lead to the fundamental problem of Old Testament history. Since 1908, W. F. Albright, "De gentibus Israe·" has been identified as 1 Chron. ii. iv. accord with certain details in 2 Samuel, and appear to refer to a half-Edomite Judah in David's time (c. 1000 B.C.). 1 More recently E. Meyer, on the basis of a larger induction, has pointed out the relation of this Judah to a large group of Edomite or Edomite-Ishmaelite tribes. 2 The stories in Genesis represent a southern treatment of Palestinian tradition, with local and southern versions of legends and myths, and with interests which could only belong to the south. 3 It has long been perceived that Kadesh in South Palestine was connected with a lawgiving and with some separate movement into Judah of clans associated with the family of Moses, Caleb, Kenites, &c. (see Exodus, Thea). With this it is natural to connect the transmission and presence in the Old Testament of specifically Kenite tradition, of the "southern" stories in Genesis, and of the stories of Levi. 4 The rise of this new Judah is generally attributed to David; but David's thrones remain isolated until some five centuries, only moving a few miles nearer Jerusalem; and this vast interval separates the old half-
Edomite or Arabian Judah from the sequel—the association of such names as Korah, Ethan and Heman with temple-psalms and psalmody. 5 It has long been agreed that biblical religion and history are indebted in some way to groups connected with Edom and North Arabia, and repeated endeavours have been made to explain the evidence in its bearing upon this lengthy period. 6 The problem, it is here suggested, is in the first instance a literary one—the literary treatment by southern groups, who have become Israelite, of a lengthy period of history. When the whole body of evidence is viewed comprehensively, it would seem that there was some movement northwards of semi-Edomite blood, tradition and literature, the date of which may be placed during the internal disorganization of Palestine, and presumably in the 8th century. Such a movement is in keeping with the course of Palestinian history from the traditional entrenchments of the Israelite tribes of the 10th century, to the relative marginalization of the tribe of Judah, the "eastern population of South Judah was of half-Arab origin" (R. W. Smith, Old Test. Jew. Church, p. 279). 7

1 Meyer and Luther, op. cit., p. 446, et passim.
2 So especially Meyer and Luther, op. cit., cf. also H. Grossmann, Zeit. f. altert. Wissens. (1909), p. 450, etc. Note also the view that the grand book of Job (g.v.) has an Edomite background.
4 On the names, see Genealogy: Biblical; Levites, § 2, end, and Encyc. Bibl. col. 1665 seq.
5 W. R. Harper (An Am. and Hosia, 1905, liv.) observes: "Every year for the last 10 years W. R. Smith brings Israel into closer relationship with Arabia;" cf. also N. Schmitt's conclusions (Hijiert Journal, 1908, p. 342), and the Jerahmeelite theory of T. R. Cheyne, who writes (Declin and Fall of the Kingdom of Judah, London 1908, p. 265, etc.) . . . . it is the greatest part of the extant literary monuments of ancient Israel are precisely those monuments whose producers were most preoccupied by N. Arabia.
6 Of Amr. In the Old Testament popular feelings knew of two phases: Edom, the more powerful brother of Jacob (or Israel)—both could share in the fate of Abraham, Isaac and Jacob—and the hatred of the treacherous Edom in the prophetic writings. Earlier phases have not survived, and the last-mentioned is relatively late, a after the southern influence had left itself upon history, legend, the Temple and the ecclesiastical bodies. On these grounds, then, it would seem that among the vicissitudes of the 8th and following centuries may be placed a movement of the greatest importance for Israelite history and for the growth of the Old Testament, one, however, which has been reshaped and supplemented (in the account of the Exodus and Invasion) and deliberately suppressed or ignored in the history of the age (viz. in Ezra-Nehemiah).
7 The unanimous recognition on the part of all biblical scholars that the Old Testament cannot be taken as it stands as a trustworthy account of the history with which it deals, necessitates a hypothesis or, it may be, a series of hypotheses, which shall enable one to approach the more detailed study of its history and religion. The curious and popular tradition that Ezra rewrote the Old Testament (2 Esd. xiv.), the concessions of conservative scholars, the even the view that the Hebrew text is too uncertain for literary criticism, indicate that the starting-point of inquiry must be the present form of the writings. The necessary work of literary analysis reached its most definite stage in the now famous hypothesis of Graf (1865-1886) and especially Wellhausen (1878), which was made more widely known to English readers, directly and indirectly through W. Robertson Smith, in the 4th edition of this Encylopedia. 8 The work of literary criticism and its application to biblical history and religion passed into a new stage as external evidence accumulated, and, more particularly since 1900, the problems have assumed new shapes. The tendency has been to assign more of the Old Testament, in its present form, to the Persian age and later; and also to work upon lines which are influenced sometimes by the close agreement with Oriental conditions generally and sometimes by the very strange divergences. It is the merit of Hugo Winckler especially to have lifted biblical history out of the somewhat narrow lines upon which it had usually proceeded, but, at the time of writing (1910), Old Testament criticism still awaits a sound reconciliation of the admitted internal intricacies and of the external evidence for Palestine and that larger area of which it forms part. Upon the convergence of the manifold lines of investigation rest all reconstructions, all methodical studies of biblical religion, law and prophecy, and all endeavours to place the various developments in an adequate historical framework.

The preliminary hypotheses, it would seem, must be both literary and historical. The varied standpoint (historical, social, legal, religious, &c.) combine with the fragmentary character of the Old Testament to a large extent of the evidence to suggest that the literature was formed through different cycles, with excision of revision of older material, and with the incorporation of other material, sometimes of older origin and of independent literal growth. Consequently, one is restricted in the first instance to seeking out that information in the form in which the later editors or compilers gave it. Different views as regards history (e.g. invasions, tribal movements, rival kingdoms) and religion (e.g. the Yahweh of Kadesh, Sinai, Jerusalem, &c.), and different priestly, prophetic and popular traditions. Ezra redrew the character of Palestinian population. Hence to weave the data into a single historical outline or into an orderly evolution of thought is to overlook the probability of bona

7 D. Dissard, Rev. Bibl., 1905, pp. 410-425. Some S. Pal. revolt is also reflected shortly before the rise of the Jewish dynasty (Jews, pp. 121, 124). The few centuries between the fall of the Herods and the beginning of the Greek period, as we may call it, were again closely connected with the Jews; an Idumean dynasty—that of the Herods—ruled in Judah, and once more there must have been a considerable amount of intermixture.
PALESTINE

OLD TESTAMENT HISTORY

side diversions of tradition and to assume that more rudimentary or primitive thought was excluded by the admitted development of religious-social ideals. The oldest nucleus of historical tradition appears to belong to Samaria, but it has been adjusted to and influenced throughout by the syncratic interests of the Deuteronomist, who was long partly with the half-Edomite and partly with the old indigenous Judean stock. 

Genesis–Kings (incomplete; some further material in Jeremiah) and the later Chronicles–Nehemiah are in their background the following:—The historical events of his age are shrouded in obscurity, but one can recognize the return of exiles from Babylon to Jerusalem and its environs—now half-Edomite—and various internal rivalries which culminated in the Maccabean war. In such circumstances a whole generation has left their mark in the Pentateuch and (the later) Chronicles, and the Samaritan succession appears to have coloured the book of Kings. These sources are then "post-exilic, and the elimination of "pre-exilic" material is relatively simple. But it is notLegv1. The second, and other material which was obviously in circulation (e.g., the non-priestly portions of Genesis). The relatively earlier group of books is now the result of two complicated and continuous redactions. Deuteronomic (Deut. Kings) and "Priestly" (Cushitero, with traces in the following books). The former is exceptionally intricate, being in its various aspects distinctly earlier, and in parts even later than the "priestly." Its standpoint, too, varies, that of its position among a wider Israelite, now half-Edomite and Judean, and now anti-Samaritan.

Moreover, there is a late incorporation of literature, sometimes untouched by and sometimes merely approximating to "Deuteronomic" language or thought. Hence the "historical" interest in the works of Jewish literature which, for example, may be seen from the Septuagint version of Joshua, Samuel and Kings, and from their internal literary structure, which suggests that only at the last stages of compilation were they brought into their present shape. Hence, to take the form to which it belongs, this historical and critical interest belongs to the last literary vicesitudes, and that similar influences (which have not affected every book in the same manner) have been at work throughout. The history of the past is the history of the whole, a subsequent to the relatively recent changes which gave birth to new organizations in Samaria and Judah. Consequently, in addition to the ordinary requirements of historical criticism, biblical studies has an added characteristic of the sources and the background of these positions. It is the criticism of sources which have both a literary and an historical compositional. Not only are the standpoints of local interest (Samaria, Benjamin, etc.) which influence both the writing and the revision of the sources (see LEVITE). Yet it is noteworthy that the traditions are usually redacted, adjusted or reinterpreted, and are not replaced by entirely new ones. Thus, the Samarians claim the traditions of the land; the Chronicler traces the connexion between "pre-exilic" and "post-exilic" material. Such a connexion is not possible; the south Palestinian cycle of tradition is adapted to the history of a descent into and an exodus from Egypt; Zadokite priests are enrolled as Aaronites, and the hierarchical traditions which fill up the whole, ancient, and post-exilic, are not the whole, the whole, and the whole.

Reshaping of Tradition.

Old priestly literature (Judg. v., 2 Sam. i.) stories of conquest and settlement, and they connect with the liturgy in Deuteronomy's covenant at Shechem and the Shechem-covenant-god (cf. Kennett, Journ. Theol. Stud., 1906, pp. 495 sqq.; Lincee, op. cit., p. 89, W. E. Erbt, Die Hebräer (1906), pp. 27 sqq.; Meyer and Luther, pp. 42 sqq., 590 sqq.). Old priestly literature is both political and religious animosity, but it is not certain that Josephus is wrong in placing the schism at the close of the Persian period; see, on this point, J. Marquart, Isr. u. Jud. Gesch. (1906), p. 57 sqq.; C. Steuernagel, Theolog. Stud. u. Krit. (1899), Berlin, pp. 173-176; C. C. Torrey, Ezra Studies (Chicago, 1910), pp. 321 sqq. Old priestly rivalries between Cultus and Babylon may explain why the mixed Samaritans became known as Cuthaeans; according to the prologue of their predecessors, "the ten tribes" had been exiled in the 8th century.

This refers to literary and history after the return of exiles and the religious reconstruction of Judah. This, or the supposed "Canaanite" theology of the period, is a mere tradition. The "writings of the time of Nehemiah" is misleading (see Torrey, op. cit., pp. 287 sqq., etc.).

The "Deuteronomic" form of Samuel, and the degradation of the literary growth of Genesis and the account of the exodus and invasion of Palestine upon the "southern" cycle of tradition.

The evidence for Jewish colonies at Elephantine in Upper Egypt (5th century B.C.) has been emphasized by some scholars, but it is probable that they were descended from the soldiers settled by Psamtek I. (7th century), and not only are they in touch with Judah and Samaria, but in Psamtek's time an effort was made to win back a branch of the Asiatic Jews by the distribution of the lands of the Old Testament (J. H. Breasted, Egypt hist. doc. iv, 506 seq.). It is already suggested that alliances to a sojourn in Egypt may refer not to the times of Jacob and Moses but to the circumstances of the 7th century B.C.

The evidence for Palestinian stories of their predecessors, or the mingling of accurate and inaccurate data in Manetho and Ctesias.

Cf. the remarkable Arabian stories of their predecessors, or the mingling of accurate and inaccurate data in Manetho and Ctesias.

It is already suggested that alliances to a sojourn in Egypt may refer not to the times of Jacob and Moses but to the circumstances of the 7th century B.C.
preserved is a problem in itself. It is very noteworthy, however, that, while no care was taken to preserve the history of the Chaldean and Persian Empires—and consequently the most confused ideas subsequently arose—the days of the Assyrian supremacy leave a much clearer imprint (cf. P. Gardner, History of the Aztecs, Book 1). On the contrary, almost to the historical significance and past. This narrative is particularly interesting for the Old Testament, which permits a possible chance that with the dynasties of Omission and Jehu the historical continuity is more critical, that older forms of prophetic literature are preserved (the times from Ahab to Jehu), and that to the reign of the great Jeroboam I (first half of the 9th century), the latter are relatively the same as the early chapters of the erstwhile prophecies passages (Amos and Hosea).

External evidence for Palestine, in emphasizing the necessity for a reconsideration of the serious difficulties in the Old Testament, exemplifies a perplexing disagreement with contemporary conditions, furnishing a more striking proof of its uniqueness and of its permanent value. The Old Testament preserves traces of forgotten history and forgotten states. It is not a direct essential part of national historical account, and the remains of a semi-heathenish past. “Canonical!” history, legislation and religion assumed their present forms, and, while the earlier stages can only incompletely be traced, the book stands at the head of subsequent literature, beginning at its agreement in External Annoyance, and influencing the growth of Mahommedanism. In leaving the land of its birth it has been taken as a whole, and for many centuries has been regarded as an infallible record of divinity granted to the people. The place of the Old Testament was not relictual; the development, man and God. Man’s primary religious feeling seeks to know, to associate, and to exercise, and this which in the Old Testament appears most perceptible, most devastating, and most tedious under critical inquiry, was necessary in order to adapt new teaching to the commonly accepted beliefs of a bygone and primitive people. The place of the Old Testament in the general education of the world is at the close of one era and at the beginning of another. After a lengthy development in the history of the human race a definite stage seems to have been reached sufficient to provide the first great picture frame of culture (Egyptian, Aegian, Babylonian) which surrounded Palestine.1 These have influenced all subsequent civilization, and it was impossible that ancient Palestine could have been isolated from early records. After inspecting the height (roughly 2500-1500 B.C.) these civilizations powerfully decayed, and we reach the middle of the first millennium B.C.—the age which is associated with the “Deuter–Isaiah” (Isa. xi–iv., with Babylonian and Philistine relations), and Phocylides and Socrates.2 This age, which comes midway between the second Egyptian dynasty (c. 3000 B.C.) and the present day, connects the decline of the Old Oriental empire with the rise of the Persians. Literature. It was the age of Zoroastrianism, but the real trend of the Persianism is towards a political upheaval, and the development of Greek thought of this period, especially interesting for the Old Testament is the teaching associated with Phocylides of Miletus; see Lincke, Samaria, pp. 47 seq.

1 C. G. A. Smith, Hist. Geog. pp. 85 sqq., also the Arab historian Ibn Khaldun on the effects of civilization upon Arab tribes (see e.g. R. A. Nicholson, Lit. Hist. of the Arabs [London, 1907], pp. 439 sqq.).

After the taking of Tyre Alexander decided to advance upon Egypt. With the exception of Gaza, the whole of Syria Palæstina (as it was called) had made its submission. A second summary form—is the narrative of the Greek historian Arrian (Anabasis, ii. 25). Apart from the facts contained in this statement, the phrasing of some importance, as the district of “Palæstina Syria” clearly includes more than the territory of the Philistines, which the adjective properly denotes (Josephus, Antiquities, i. 6, 2, xii. v. 10). From the military point of view—and Arrian drew upon the memoirs of two of Alexander’s lieutenants—the significant thing was that not merely was the coast route from Tyre to Gaza open, but also there was no danger of a flank attack as the expeditionary force proceeded. Syrian Syrian, in fact, is here synonymous with what is commonly called Palestine. Similarly Josephus quotes from Herodotus the statement that the Syrians in Palæstina are circumcised and profess to have learned the practice from the Egyptians (C. Apionem, i. 23, §§ 169, 171, Niese); and he comments that the Jews are the only inhabitants of Palæstina who do so. These two examples of the wider use of the adjective and noun seem to testify to the regained predominance of the Philistines in the land of Canaan.

But, in spite of the statement and silence of Arrian, Jewish tradition, as reported by Josephus (Ant. ii. 8, 3 sqq.), represents the high priest at Jerusalem as refusing Alexander’s offer of alliance and request for supplies. The Samaritans—the Jews ignored in their records all other inhabitants of Palæstina—counted his favour, but the Jews kept faith with Darius so long as he lived. Consequently a visit to Jerusalem is interpolated in the journey from Tyre to Gaza; and, Alexander, contrary to all expectation, is made to respect the high priest’s passive resistance. He had seen his figure in a dream; and so he sacrificed to God according to his direction, inspected the book of Daniel, and gave them—and at their request the Jews of Babylon and Media—leave to follow their own laws. The Samaritans were prompt to claim advantage, but were forced to confess that, though they were Hebrews, they were called the Sidonians of Shechem and were not Jews. The whole story seems to be a literary invention in the first century B.C., and is certainly wrong as to the personal identity of the high priest. The second account is entirely based on an anachronism in the Alexander: the Jews enjoyed religious liberty. The Samaritans are the villains of the piece. But it is possible that Palestinian Jews accompanied the expedition as guides or exerted their influence with Jews of the Dispersion on behalf of Alexander.

It appears from this tradition that the Jews of Palæstina occupied little more than Jerusalem. There were kings of Syria in the train of Alexander who thought he was mad when he bowed before the high priest. We may draw the inference that they formed an insignificant item in the population of a small province of the Persian Empire, and yet doubt whether they did actually refuse—all of the inhabitants of Palæstina—to submit to the conqueror of the whole. At any rate they came into line with the rest of Syria and were included in the province of Coele-Syria, which extended from the Taurus and Lebanon range to Egypt. The province was entrusted first of all to Alexander’s brother in law, and then to a puppet king named Andromachus (Curtius iv. 9, 1). In 311 B.C. the Samaritans rebelled and burned Andromachus alive (Curtius iv. 8, 9); Alexander came up from Egypt, punished the rebels, and settled Macedonians in their city. The loyalty of the Jews he rewarded by granting them Samaritan territory free of tribute—according to a statement attributed by Josephus (c. Apionem, ii. § 43, Niese) to Hezekaias.

After the death of Alexander (323 B.C.) Ptolemy Lagi, who became satrap and then king of Egypt by right of conquest (Diodorus xviii. 39), invaded Coele-Syria in 320 B.C. Then or after the battle of Gaza in 312 B.C. Ptolemy was opposed by the Jews and entered Jerusalem by taking advantage of the Sabbath rest (Agatharchides ap. Jos. c. Apionem 1. 22, §§ 209 seq.; cf. Ant. xii. i, 1). Whenever this occupation...
took place. Ptolemy became master of Palestine in 312 B.C.,
and, though, as Josephus claims, he may have disgraced
his reputation, by momentary severity at the outset, later he
created in the minds of the Jews the impression that in Palestine or in
Egypt he was—in deed as well as in name—their preserver.
Since 312 B.C. Palestine had been occupied by the forces of
Antigonus. Ptolemy's successful forward movement was
undertaken by the advice of Seleucus (Diodorus xix. 80 sqq.),
who followed it up by regaining possession of Babylon.
So the Seleucid era began in 312 B.C. (cf. Maccabees, i. 10) and the
dynasty of Seleucus justified the "prophecy" of Daniel (xi. 2):
"And the king of the south (Ptolemy) shall be strong, but one of
his captains (Seleucus) shall be strong above him and have
dominion" (see SELEUCID DYNASTY).
Abandoned by his captain and future rival, Seleucus, Ptolemy
retired and left Palestine to Antigonus for ten years. In 302
B.C., by terms of his alliance with Seleucus, Lysimachus and
Cassander, he set out with a considerable force and subjugated all
the cities of Coele-Syria (Diodorus xx. 113). A rumour of the
defeat of his allies sent him back from the siege of Sidon into
Egypt, and in the partition of the empire, which followed their
victory over Antigonus at Issus, he was ignored. But when
Seleucus came to claim Palestine as part of his share, he
found his old chief Ptolemy in possession and retired under
protest. From 301 B.C.—108 B.C. Palestine remained, with short
interruptions, in the hands of the Ptolemies.
Of Palestine, as it was during this century of coexistence,
dominion, there is much to be learned from the traditions,
reported by Josephus (Ant. xii. 4), in which the
career of Joseph, the son of Tobiah, is glorified as
the means whereby the national misfortunes were
rectified. This Joseph was the nephew of Onias, son of Simon
the Righteous, and high priest. Onias is described—in order
to enhance the glory of Joseph—as a man of small intelligence and
deficient in wealth. In consequence of this deficiency he
failed to pay the tribute due from the people to Ptolemy, as his
fathers had done, and is set down by Josephus as a miser who
cared nothing for the protest of Ptolemy's special ambassador.
Considering the character of Joseph as it was revealed by
prosperity, one is tempted to find other explanations of his
conduct than avarice. It is clearly indicated that the Jews as a
whole were poor, and it is admitted that Onias was not wealthy.
Perhaps it was the Sabbatical year, when no tribute was due.
Perhaps Onias would not draw upon the sacred treasure in order
to pay tribute to Ptolemy. In any case Joseph borrowed money
from his friends in Samaria; and this point in the story proves
that the Jews were supposed to have dealings with the Samari-
tans at the time and could require of them the last proof of
friendship. Armed with his borrowed money, Joseph betook
himself to Egypt; and there outbid the magnates of Syria when
the taxes of the province were put up to auction. He had
gained the ear of the king by entertaining his ambassador, and
the representatives of the cities—the Greek cities of Syria were
discouraged by the speech and conduct of these new governors
and the Jewish population to procure him more money from the king's friends. When he began to collect
taxes he was met with refusal and insult at Ascalon and at
Scythopolis; but he executed the chief men of each city and sent
their goods to the king. Warned by these examples, the Syrians
opened their gates to him and paid their taxes. For twenty-
two years he held his office and was to all intents and purposes
governor of Syria, Phoenicia and Samaria—"A good man "
(Josephus calls him) "and a man of mind, who rescued the
people of the Jews from poverty and weakness, and set them on
the way to comparative splendour" (Ant. xii. 4, 10).
The story illustrates the rise of a wealthy class among the
Jews of Palestine, to whom the tolerant and distant rule of the
Ptolemies afforded wider opportunities. At the beginning it
is said that the Samaritans were prosperous and persecuted
the Jews, but this Jewish hero embracing his opportunities reversed
the situation and presumably paid the tribute due from the Jews
by exacting more from the non-Jewish inhabitants of his province.
He is a type of the Jews who embraced the Greek way of life
as it was lived at Alexandria; but his influence in Palestine was
insidious rather than actively subversive of Judaism. It was
different when the Jews who wished to be men of the world took
their Hellenism from the Seleucid court and courted the favour of
Antiochus Epiphanes.
Halfway through this century (249 B.C.) the desultory warfare
between Egypt and the Seleucid power came to a temporary
end (Dan. xi. 6). Ptolemy II. Philadelphus gave his daughter
Berenece with a great dowry to Antiochus II. Theos. When
Ptolemy died (247 B.C.), Antiochus' divorced wife Laodice was
restored to favour, and Antiochus died suddenly in order that
she might regain her power. Berenece and her son were likewise
removed from the path of her son Seleucus. In the vain hope
of protecting his sister Berencie, the new king of Egypt Ptolemy
III. Euergetes I., invaded the Seleucid territory, "entered the
fortress of the king of the north " (Dan. xi. 7 sqq.), and only
returned—laden with spoils, images captured from Egypt by
Cambyses, and captives (Jerome on Daniel loc. cit.)—to put down a
domestic rebellion. Seleucids reconquered northern Syria without
much difficulty (Justin xxvii. 1, 1), but on an attempt to seize
Egypt, his ally Byblos (Justin xxvii. 2, 4), Palestine he was signally
defeated by Ptolemy (Justin xxvii. 2, 4).
In 223 B.C. Antiochus III. the Great came to the throne of the
Seleucid Empire and set about extending its boundaries in
different directions. His first attempt on Palestine (221 B.C.) failed; the second succeeded by the treachery of Ptolemy's lieutenant, who had been
recalled to Alexandria in consequence of his successful resistance
to the earlier invasion. But in spite of this assistance the
conquest of Coele-Syria was not quickly achieved; and when
Antiochus advanced in 218 B.C. he was opposed by the Egyptians
on land and sea. Nevertheless he made his way into Palestine, planted
garrisons at Philletoria on the Sea of Galilee and Scytho-
polis, and finally stormed Rabban-ammon (Philadelphia) which
was held by partisans of Egypt. Early in 217 B.C. Ptolemy
Philopater led his forces towards Raphia, which with Gaza
was now in the hands of Antiochus, and drove the invaders back.
The great multitude was given into his hand, but he was not to
be strengthened permanently by his triumph (Dan. xi. 11 sqq.).
Polybius describes his triumphal progress (v. 86): "All
the cities vied with one another in returning to their allegiance.
The inhabitants of those parts are always ready to accommodate
themselves to the situation of the moment and prompt to pay the
courtesies required by the occasion. And in this case it was
natural enough because of their deep-seated affection for the
royal house of Alexandria." When Ptolemy Philopater died in 205 B.C., Antiochus and
Philip of Macedon, his nominal friends, made a secret compact
for the division of his possessions outside Egypt. The time had
come of which Daniel (xi. 13 sqq.) says: "The king of the north
shall return after certain years with a great army and with much
riches. And in those times there shall stand up against
the king of the south; also the robbers of thy people shall exalt themselves to establish the vision; but they shall fail." It was this period apparently alluded to Antiochus and he came to
take it, while Philip was at a distance in the far-off Illyricum and
Asia Minor. Already he had allies among the Jews and, if Daniel
is to be trusted, there were other Jews who rose up to shake off the
yoke of foreign supremacy, Seleucid or Egyptian, and suc-
cceeded only in rendering the triumph of Antiochus easier of
achievement. But in the year 200 B.C. Rome intervened with an
embassy, which declared war upon Philip and directed Antiochus and Ptolemy to make peace (Polyb. xvi. 27). And
in 198 B.C. Antiochus heard that Scopas, Ptolemy's hired
commander-in-chief had retaken Coele-Syria (Polyb. xvi. 39) and
had subdued the nation of the Jews in the winter. For these
sufficient reasons Antiochus hurried back and defeated
Scopas at Panaces, which was known later as Caesarea Philippi
(Polyb. xvi. 18 seq.). After his victory he took formal possession
of Batanea, Samaria, Abila and Gadara; "and after a little
the Jews who dwelt round about the shrine called Jerusalem
came over to him " (Polyb. xvi. 36). Only Gaza withstood
him, as it withstood Alexander; and Polybius (xvi. 40) goes to

PALESTINE

[TO A.D. 70]
praise their fidelity to Ptolemy. The siege of Gaza was famous; but in the end the city was taken by storm, and Antiochus, secure at last of the province, which his ancestors had so long coveted, was at peace with Ptolemy, as the Roman embassy directed. From Palestine Antiochus turned to the Greeks of Asia Minor, and in 156 B.C. he was in Thrace. There he was confronted by the ambassadors of Rome, who expressed their surprise at his actions. Antiochus replied that he was recovering the territory won by Seleucus his ancestor, and inquired by what right did the Romans dispute with him about the free cities in Asia (Polyb. xviii. 33 sqq.). The conference was broken off by a false report of Ptolemy’s death, but war between Rome and Antiochus was clearly inevitable—and Antiochus was joined by Hannibal. After much diplomacy, Antiochus advanced into Greece and Rome declared war upon him in 151 B.C. (Livy xxxvi. 1). He was defeated on the seas and driven first out of Greece and then out of Asia Minor. His army was practically destroyed at Magnesia, and he was forced to accept the terms of peace, which the Romans had offered and he had refused before the battle. By the peace of Apamea (188 B.C.) he abandoned all territory beyond the Taurus and agreed to pay the whole cost of the war. He had stood in the beauteous land—the land of Israel—with destruction in his hand. He had made agreement with Ptolemy. He had turned his face unto the islands and had taken many. But now a command had put an end to his defiance and had even returned his respect unto Rome (Dan. xi. 10–18). After Magnesia, Xenien said “King Antiochus the Great was” (Appian, Syr. 37); and the by-word was soon justified in fact, for he plundered a temple of Bel at Elymais to replenish his exhausted treasury and met the fitting punishment from the gods at the hands of the inhabitants (Diodorus xxix. 15). He stumbled and fell and was not found (Dan. xi. 19).

The need which drove Antiochus to this sacrilege rested heavily upon his successor Seleucus IV. (reigned 187–175 B.C.).

The indemnity still had to be paid and Daniel designates Seleucus as “one that shall cause an exactor to pass through the glory of the kingdom” (xi. 20). A tradition preserved in 2 Macc. iii. describes the attempt of Heliodorus, the Seleucid prime minister, to plunder the temple at Jerusalem. The holy city lay in perfect peace and the laws were very well kept because of the piety of Onias the high priest. But one Simon, a Benjamite, who had become guardian of the temple, quarrelled with Onias about the city market, and reported to the governor of Coele-Syria and Pheonia that the treasury was full of untold sums of money. The priests and people besought Heliodorus to leave this sacred treasure untouched, but he persisted and—in answer to their prayer— Select, and horses were very necessary to him if he was to establish himself in Syria. Onias had proceeded to Antioch to explain the disorder and bloodshed due to Jason’s followers, and so Jason, high priest of the Jews by grace of Antiochus, had his way. The existing privileges, which the Jews owed to their ambassador to Rome, were thrust aside. In defiance of the law a gymnasium was set up under the shadow of the citadel. The young men of the upper classes assumed the Greek hat, and gathered together into a gild of ephebi on the Greek model. In fact Jason established in Jerusalem the institutions which Strabo expressly describes as visible signs of the Greek way of life—“gymnasia and associations of ephebi and clans and Greek names borne by Romans” (v. p. 364, referring to Neapolis)—and that on his own initiative. The party who wished to make a covenant with the heathen (7 Macc. i. 11 sqq.) were in the majority; and so far and so long as they were in the ascendant Antiochus was rid of his chief danger in Palestine, the debatable land between Syria and Egypt. At first Egypt was well disposed to him, as Cleopatra his sister was regent. But she died in 173 B.C.

The struggle for the possession of Palestine began in 170 B.C., when Rome was preoccupied with the war against Perseus of Macedonia. Antiochus sent an ambassador to Rome to protest that Ptolemy, contrary to all law and equity, was attacking him (Polyb. xxvii. 17). In self defence, therefore, Antiochus advanced through Palestine and defeated the Egyptian army near Pelusium on the frontier. At the news the young king, Ptolemy Philometor, fled by sea, only to fall into his uncle’s hands; but his younger brother, Ptolemy Euergetes II., was proclaimed king by the people of Alexandria (Polyb. xxviii. 8). Thus Antiochus entered Egypt as the champion of the rightful king and laid siege to Alexandria, which was held by the usurper. When he abandoned the siege and returned to Syria, Philometor, whom he had established at Memphis, was reconciled with his brother, being convinced of his protector’s duplicity by the fact that he left a Syrian garrison in Pelusium. In 168 B.C. Antiochus returned and found that the pretext for his presence there was gone. Moreover the defeat of Perseus by Pydna set Rome free to take a strong line in Egypt. As he approached Alexandria Antiochus met the Roman ambassador, and, after a brief attempt at evasion, accepted his ultimatum on the spot. He evacuated Egypt and returned home cowed (Dan. xi. 30; cf. Polyb. xxx. 11). Later he could attend the celebration of the Roman triumph over Macedonia, and surpass it by a festival at Antioch in honour of his conquest of Egypt (Polyb. xxxi. 3–5), but the loss of Pelusium made it imperative that he should be sure of Palestine. His friends the Hellenizing Jews had split up into factions. Menelaus, the brother of Simon the Benjamite, had bought the high-priesthood over the head of Jason, who fled into the country of the Ammonites, in 172 B.C. (2 Macc. v. 5 sqq.). To get rid of an adversary of the priests (the priestly tribe) Menelaus persuaded the deputy of Antiochus, who was dealing with a revolt at Tarsus, to put Onias to death. Antiochus, on his return, had his deputy executed and went for the dead Onias. But Menelaus managed to retain his position, and his accusers were put to death. Antiochus could pity Onias, who had been tempted from the sanctuary at Daphne, but he needed an ally in Jerusalem—and money. Then, during the first or second invasion of Egypt, Jason, hearing that Antiochus was dead, returned suddenly and massacred all the followers of Menelaus who did not take refuge in the citadel. He had some claim to the loyalty of such pious Jews as remained, because he was of the tribe of Levi—in spite of the means he, like Menelaus, had employed to get the high-priesthood. His temporary success reveals the strength of the party who wished to adopt the Greek way of life without consenting to the complete substitution of the authority of Antiochus for the prescriptions of the Mosaic Law. It was also a warning to Antiochus, who returned to exact a bloody vengeance and to loot the Temple (169 or 168 B.C.). After the evacuation of Egypt, Antiochus followed out the policy which had suggested to him at the first. Jerusalem was suddenly occupied by one of his captains, and a garrison was planted in a new fortress on Mount Zion. Then to coerce the Jews into conformity, the Law was outlawed in the Holy Place. The worship of Zeus Olympus replaced the worship of Yahweh, and swine
PALESTINE

[TO A.D. 70]

were offered as in the Eleusinian mysteries. At the same time the Samaritan temple at Shechem was made over to Zeus Xenius: it is probable that the Samaritans were, like the Jews, divided into two parties. The practice of Judaism was prohibited by a royal edict (1 Macc. i. 47-63; 2 Macc. vii. 43), and some of the Jews died rather than disobey the law of Moses. It is legitimate to suppose that this attitude would have surprised Antiochus if he had heard of it. His Jewish friends, first Jason and then Menelaus, had been enlightened enough to throw off their prejudices, and, as far as he could know, they represented the majority of the Jews. Zeus was for him the supreme god of the Greek pantheon, and the syncretist, which he suggested for the sake of uniformity in his empire, assuredly involved no indignity to the only God of the Jews. At Athens Antiochus began to build a vast temple of Zeus Olympius, in place of one begun by Ptolemy; but it was only finished by Hadrian in A.D. 130. Zeus Olympius was figured on his coins, and he erected a statue of Zeus Olympius in the Temple of Apollo at Daphne. More, he identified himself—Epiphanes, God Manifest—with Zeus, when he magnified himself above all other gods (Dan. xi. 37). To the minority of strict Jews he was therefore "the abomination of desolation standing where he ought not"; but the majority he carried with him and, when he was dying (165 B.C.) during his eastern campaigns, he wrote to the loyal Jews as their fellow citizen and general, exhorting them to preserve their present goodwill towards him and his son, on the ground that his son would continue his policy in gentleness and kindness, and so maintain friendly relations with them (2 Macc. ix.).

Jewish Revolt.

The Jews who still deserved the name the policy of Antiochus wore a very different aspect. Many of them became martyrs for the Law, and for a time none would raise his hand to defend himself on the Sabbath if at all. No record remains of the success of the Athenian missionary whom Antiochus sent to preach the new Catholicism; but the soldiers at any rate did their work thoroughly. At last a priestly family at a village called Modein committed themselves to active resistance; and, when they suspended the Sabbath law for purposes of self defence, they were joined by the Hasidaeans (Assidaeans), who seem to have been the spiritual ancestors of the Pharisees. The situation was plain enough: unless the particular law of the Sabbath was suspended there would soon have been none to keep the Law at all in Palestine. Jerusalem had apostatized, but the country so far as it was populated by Jews was faithful. Under Judas Maccabeus the outlaws wandered up and down re-establishing by force their present goodwill towards him and his son. In 165 B.C., however, the regent of Syria conceded the measure of toleration they required with the approval of Rome; and in 164 B.C. the temple was purged of its desecration. But Judas did not lay down his arms, and added to his resources by rescuing the Jews of Galilee and Gilead and settling them in Judaea (1 Macc. v.). The Nabataean Arabs and the Greeks of Scythopolis befriended them, but the province generally was hostile. In spite of their hostility Judas more than held his own until the regent defeated him at Bethzachariah. The rebels were driven back on Mount Zion and were there besieged (163 B.C.). The rumour of a pretender to the throne saved them from destruction, and they capitulated, exchanging the strongholds they had for their lives. At any rate the time of compulsory fusion with the Greeks was ended once for all. In 162 B.C., Demetrius, the son of Seleucus, escaped from Rome and was proclaimed king. Like Antiochus Epiphanes, who also had spent his youth as a hostage in Rome, he was inclined to listen to the Hellenizing Jews, whom he found assembled in full force at Antioch, and to support them against Judas, who was now supreme in Judaea. But he dealt more surely with them: instead of a pagan missionary he sent them Alcimus, a legitimate high-priest, who detached the Hasidaeans from Judas. Indeed, Alcimus and his company did more mischief among the Israelites than the heathen (1 Macc. vii. 23) and Judas took vengeance upon those who deserted from him. Nicanor was appointed governor and prevailed upon Judas to settle down like an ordinary citizen. But Alcimus complained to the king and Judas fled just in time to escape being sent to Antioch as a prisoner. In the battle of Adasa, which soon followed, Nicanor was defeated and his forces annihilated, and the Jews who came out of all the villages of Judaea (1 Macc. vii. 46). At this point (162 B.C.) Judas sent an embassy to Rome and an alliance was concluded (1 Macc. viii.), too late to save Judaeas from the determined and victorious attack of Demetrius. The death of Judas at Elasa left the field open to the apostates, and his followers were reduced to the level of roving brigands. The Syrian general made fruitless attempts to capture them, and build forts in Judaea whose garrisons should harass Israel (1 Macc. ix. 50-53), but Jonathan and Simon, brothers of Judas, found their power increase until Jonathan ruled at Michmas as judge and destroyed the godless out of Israel (1 Macc. ix. 73).

In 153 B.C. there appeared another of the series of pretenders to the Syrian throne, to whose rivalry Jonathan, and Simon after him, owed the position they acquired for themselves and their nation. Jonathan was recognized as the head of the Jews, and his prestige and power were such that the charges of the Hellenizing Jews received scant attention. As the years went on he became Strategus and the Syrian garrisons were withdrawn from all the strongholds except Jerusalem and Bethzur. In 147 B.C. he defeated the governor of Coele-Syria in another civil war and received Ekon as his personal reward—"Ekon" was said in the name of the prophet Zachariah (ix. 7), "and Ekon shall be as a Jebusite." The king for whom he fought was defeated; but his successor acceded to the demands of Jonathan, added three districts of Samaria to Judaea and freed the whole from tribute. The next king confirmed this and appointed Simon military commander of the district stretching from Tyre to Egypt. So with Syrian as well as Jewish troops the brothers set about subduing Palestine and Jonathan sent ambassadors in the name of the high-priest and people of the Jews to Rome and Sparta. In spite of the treacherous murder of Jonathan by the Syrian general, the prosperity of the Jews was more than maintained by Simon. The port of Joppa, which was already occupied by a Jewish garrison, was cleared of its inhabitants and populated by Jews. Finally, in 141 B.C., the new era began: the yoke of the heathen was taken away from Israel and Simon was declared high-priest and general and ruler of the Jews for ever until there should arise a faithful prophet (1 Macc. xii. 41, xiv. 41).

In 135 B.C. the political ambitions of the Jews were rudely checked: a new king of Syria, Antiochus Sidetes, resented their treatment by the Romans at Joppa and Gaza and drove them back into Jerusalem. In 134 famine compelled John Hycanus, who had succeeded his father Simon, to make a belated compliance with the king's demands. The Jews laid down their arms, dismantled Jerusalem, and agreed to pay rent for Joppa and Gaza. But in 129 B.C. Antiochus died fighting in the East and for sixty-five years the Jews enjoyed independence. John Hycanus was not slow to take advantage of his opportunities. He conquered the Samaritans and destroyed the temple on Mount Gerizim. He subdued the Edomites and compelled them to become Jews. Soon after his death his sons stormed Samaria, which Alexander the Great had colonized with Macedonian soldiers, and razed it to the ground. Judas Aristobulus, who succeeded and was the first of the Hasmonaean, called himself king and followed his father's example by compelling the Ituraeans to become Jews, and so creating the Galilee of New Testament times. In this case, as in that of the Edomites, it is natural to suppose that there existed already a nucleus of professing Jews which made the wholesale conversion possible. By this time (105 B.C.) it was clear that the Hasmonaean were—from the point of view of a purist—practically indistinguishable from the Hellenizers whom Judas had opposed so keenly, except that they did not abandon the formal observances of Judaism, and even enforced them upon foreigners. Consequently the Jews were divided into two parties—Pharisees and Sadducees—of whom the Pharisees cared only for doing or}
enduring the will of God as revealed in Scripture or in the events of history. This division bore bitter fruit in the reign of Alexander Jannaeus (106-78 B.C.), who by a standing army achieved a territorial expansion which was little to the mind of the Pharisees. At first his attack upon Ptolemais brought him into conflict with Egypt, in which he was worsted, but the Jewish general who commanded the Egyptian army persuaded the queen to evacuate Palestine. Then he turned to the country east of the Jordan, and then to Philistia. Later he was utterly defeated by a king of Arabs and fled to Jerusalem, only to find that the Pharisees had raised his people against him and would only be satisfied by his death. The rebels' appeal to the Seleucid governor of part of Syria (88 B.C.) caused a revulsion in his favour, and finally he made peace by more than Roman methods. Aretas, the Arabian king, pressed him hard on the south and the east, but he was able to make some conquests still on the east of the Jordan. In spite of his quarrel with the Pharisees, he seems to have offered the cities he conquered the choice between Judaism and destruction (Jos. Ant. xiii. 15, 4). Under Alexander, his widow (78-69 B.C.), the Pharisees ruled the Jews and no expansion of the kingdom was attempted. It was threatened by Tigranes, king of Armenia, who then held the Syrian Empire, but a bribe and the imminence of the Romans (Jos. Ant. xii. 16, 4; War i. 5, 3) saved it. At her death a civil war began between her sons, which left the way open for Rome. Pompey's lieutenant Scaurus entered Syria in 65 B.C., after the final defeat of Mithradates, and Pompey soon followed to take command of the situation. Three parties pleaded before him, the representatives of the rival kings and a deputation from the people who wished to obey no king, but only the priests of their God (Jos. Ant. xiv. 3, 2.) Pompey finally decided in favour of Hyrcanus, and entered Jerusalem by the aid of his party. The adherents of Aristobulus seized and held the temple mount against the Romans, but on the Day of Atonement of the year 63 B.C. their position was stormed and the priests were put to death (Jos. Ant. xiv. 4, 2; War i. 7). Hyrcanus was left as high-priest—not king of the Jews—and his territory was curtailed. The coast towns and the Decapolis, together with Samaria and Scythopolis, were incorporated in the new Roman province of Syria.

In 61 B.C. Pompey celebrated the third of a series of triumphs over Africa, Europe and Asia, and in his train, among the prisoners of war, was Aristobulus, king of Judea. Palestine meanwhile remained quiet until 57 B.C., when Alexander, the son of Aristobulus, escaped from his Roman captivity and attempted to make himself master of his father's kingdom. Aulus Gabinius, the new proconsul of Syria, defeated his hastily gathered forces, besieged him in one of the fortresses he had managed to acquire, and induced him to abandon his attempt in return for his life. The impotence of Hyrcanus was so obvious that Gabinius proceeded to deprive him of all political power by dividing the country into four quarters, having Jerusalem, Gaza, Amathus, Jericho, and Sepphoris, as their capitals. Other raids, headed by Aristobulus, or his son, or his adherent Ptolemaus, disturbed Palestine during the interval between 57 and 51 B.C. and served to create a prejudice against the Jews in the mind of their masters. But with the civil wars which began in 49 B.C. there came opportunities which Hyrcanus, at the instance of Antipater, used to ingratiate himself with Caesar. Once more, as in the days of Simon, the suzerain power was divided against itself, and, though Rome was as strong as the Seleucids had been weak, Caesar was grateful. For timely help in the Egyptian War of 47 B.C. Hyrcanus was rewarded by the title of Ethnarch, and Antipater with the Roman citizenship and the office of procurator of Judea. The sons of Antipater became deputies for their father; and it appears that Galilee, which was entrusted to Herod, fell within his jurisdiction.

The power of this Idumean family provoked popular risings and Antipater was poisoned. But Herod held his ground as governor of Coele-Syria and retained the favour of Cassius and Mark Antony in turn, despite the complaints of the Jewish nobility. In 42 B.C., however, the tyrant of Tyre encroached upon Galilean territory and in 40 B.C. Herod had to fly for his life before the Parthians. Even as a landless fugitive Herod could count upon Roman support. At the instance of Mark Antony, and with the assent of Octavian, the senate declared him king of Judea, and after two years' fighting he made his title good. Antigonus, whom the Parthians had set upon his throne, was beheaded by his Roman allies (37 B.C.). As king of the Jews (37-3 B.C.) Herod was completely subject and eagerly subservient to his Roman masters. In 34 B.C. (for example) or earlier, Mark Antony gave Cleopatra the whole of Phoenicia and the coast of the Philistines south of Eleusethus, with the exception only of Tyre and Sidon, part of the Arabian territory and the district of Jericho. Herod acquired and leased Jericho, the most fertile part of his kingdom, from Cleopatra. In the war between Antony and Octavian Cleopatra prevented Herod from joining Antony and so left him free to pay court to Octavian after Actium (31 B.C.). A year later Octavian restored to the Jewish kingdom Jericho, Gadara, Hippos, Samaria, Gaza, Anthedon, Joppa and Stratton's Tower (Caesarea). Secure of his position, Herod began to build temples and palaces and whole cities up and down Palestine as visible embodiments of the Greek civilization which was to distinguish the Roman Empire from barbarian lands. A sedulous courtier, he was rewarded with the confidence of Augustus, who ordered the procurators of Syria to do nothing without taking his advice. But with the establishment of (relatively) universal peace Palestine ceased to be a factor in general history. Herod the Great enlarged his borders and fostered the Greek civilization of the cities under his sway. After his death his kingdom was dismembered and gradually came under the direct rule of Rome. Herod Agrippa (A.D. 41-44) revived the glories of the reign of Alexander and won the favour of the Pharisees; but his attempt to form a confederacy of client-princes was nipped in the bud. Even the war which ended with the destruction of Jerusalem in A.D. 70, and the rebellion under Hadrian, which led to the edict forbidding the Jews to enter Jerusalem, are matters proper to the history of the Jews.

References to authorities other than Josephus are given in the course of the article; his Antiquities and War are the chief source for the period. All modern authorities are given by Schürer.

J. H. A. H.)

III.—From A.D. 70 to the Present Day.

Owing to the peculiar conditions of the land and the varied interests involved in it, the later history may best be treated in four sections. In the first the general political history will be set forth; in the second a sketch will be given of the cult of the "holy places"; the third will contain some particulars regarding the history of modern colonization by foreigners, which, while it has not affected the political status of the country, produced very considerable modifications in its population and life; and the fourth will consist of a brief notice of the progress of exploration and scientific research whereby our knowledge of the past and the present of the land has been systematized.

1. Political History from A.D. 70.—The destruction of Jerusalem was followed by the dispersal of the Jews, of whom till then it had been the religious and political centre. The first seat of the sanhedrin was at Jamnia (Yehna), where the Rabbinic system began to be formulated. This extraordinary spiritual tyranny, for it seems little else, acquired a wonderful hold and exercised a singularly unifying power over the scattered nation. The sharp contrasts between its compulsory religious observances and those of the rest of the world prevented such an absorption of the Jewish people into the Roman Empire as had caused the disappearance of the ten tribes of Israel by their merging with the Assyrians.

It would appear that at first, after the destruction of the city, no specially repressive measures were contemplated by the conquering Romans, who rather attempted to reconcile the Jews to their subject state by a leniency which had proved successful in the case of other tribes brought by conquest within the empire.
of comparative quiet in Palestine, with no external political interference. The country was nominally Christian; the only hostility it displayed being that of the development of pilgrimage and of the cult of holy places and relics, varied by occasional persecutions of the Jews. The elaborate building operations of Justinian (527–565) must not be forgotten. The “Golden Gate” of the Temple area and part of the church which is now the El-Aksa Mosque at Jerusalem, are due to him.

Not till 611 do we find any event of importance in the uninteresting record of Byzantine sovereignty. But this and the following years were signalized by a series of catastrophes of the first magnitude. Chosroes II. (q.v.), king of Persia, made an inroad into Syria; joined by the Jews, anxious to revenge their misfortunes, he swept over the country, carrying plunder and destruction wherever he went. Monasteries and churches were burnt and sacked, and Jerusalem was taken; the Holy Sepulchre church was destroyed and its treasures carried off; the other churches were likewise razed to the ground; the patriarch was taken prisoner. It is alleged that 90,000 persons were massacred. Thus for a time the province of Syria with Palestine was lost to the empire of Byzantium.

The Emperor Heraclius reconquered the lost territory in 629. But his triumph was short-lived. A more formidable enemy was already on the way, and the final wrestling of Syria from the feeble relics of the Roman Empire was imminent.

The separate tribal units of Arabia, more or less impotent when divided and at war with one another, received for the first time an indissoluble bond of union from the prophet Mahomet, whose perfect knowledge of human nature (at least of Arab human nature) enabled him to formulate a religious system that was calculated to command an enthusiastic acceptance by the tribes to which it was primarily addressed. His successor, Abu Bekr, called on the tribes of Arabia to unite and to capture the fertile province of Syria from the Christians. Heraclius had not sufficient time to prepare to meet this new foe, and was defeated in his first engagement with Abu Bekr. (For the general history of this period see CALIPHATE.) The latter seized Bosra and proceeded to march to Damascus. He died, however, before carrying out his design (a.d. 634), and was succeeded by Omar, who, after a siege of seventy days entered the city. Other towns fell in turn, such as Caesarea, Sebusteh (Samaria), Nablus (Shechem), Lydd, Jaffa.

Meanwhile Heraclius was not idle. He collected a huge army and in 636 marched against the Arabs. The latter retreated to the Yarmuk River, where the Byzantines met them. Betrayed, it is said, by a Christian who had suffered personal wrongs at the hands of certain of the Byzantine generals, the army of Heraclius was utterly defeated, and with it fell the Byzantine Empire in Syria and Palestine.

After this victory Omar's army marched against Jerusalem, which after a feeble resistance capitulated. The terms of peace, though on the whole moderate, were of a galling and humiliating nature, being ingeniously contrived to make the Christians ever conscious of their own inferiority. Restrictions in church-building, in dress, in the use of beasts of burden, in social intercourse with Moslems, and in the use of bells and of the sign of the cross were enforced. When these terms were agreed upon and signed Omar, under the leadership of the Christian patriarch Sophronius, visited the Holy Rock (the prayer-place of David and the site of the Jewish temple). This he found to be defiled with filth, spread upon it by the Christians in spite of the Jews. Omar and his followers in person cleaned it, and established the place of prayer which, though later rebuilt, has borne his name ever since.

Dissensions and rivalries soon broke out among the Moslem leaders, and in 661 Moawiya, the first caliph of the Omayyad dynasty, transferred the seat of the caliphate from Mecca to Damascus, where it remained till the Abbasids seized the sovereignty and transferred it to Bagdad.
PALESTINE

623

From A.D. 70

The Crusades.

The Crusades continued till 1092, when Palestine suffered its next invasion. This was that of the Seljuk Turks from Khorasan. On behalf of their king, the Khwarizman general Atsiz invaded Palestine and captured Jerusalem and Damascus, and then marched on Egypt to carry out his original purpose of destroying the Fatimites. The Egyptians, however, repulsed the invaders and drove them back, retaking the captured Syrian cities.

The sufferings of the Christians and the desecrations of their sacred buildings during these troubled times created widespread indignation throughout the west: and this indignation was inflamed into fury by Peter the Hermit, a native of Picardy, who in early life had been a soldier. In 1095 he went in pilgrimage to Jerusalem, and in his wrath at the miseries of the pilgrims he returned to Europe and preached the duty of the Church to rescue the "holy places" from the infidel. The Church responded, and under Peter's leadership a motley crowd, principally of French origin, set out in 1096 for the Holy Land. Others, under better generalship, followed; but of the 600,000 that started from their homes only about 40,000 succeeded in reaching Jerusalem, ill-dressed, famished and battles by the way having reduced their ranks. They captured Jerusalem, however, in July 1099, and the leader of the assault, Godfrey of Boulogne, was made king of Jerusalem.

So was founded the Latin kingdom of Jerusalem, whose history is one of the most painful ever penned (see CRUSADES). It is a record of almost unredempted "envy, hatred, and malice," and of vice with its consequent diseases, all rendered the more repulsive in that its transactions were carried on in the name of religion. For 88 turbulent years this feudal kingdom was imposed on the country, and then it disappeared as suddenly as it came, leaving no trace but the ruins of castles and churches, a few place-names, and an undying hereditary hatred of Christianity among the native population.

The abortive Second Crusade (1147), led by the kings of France and Germany, came to aid the rapidly weakening Latin kingdom after their failure to hold Edessa against Nureddin, the ruler of northern Syria.

In 1173 Nurreddin died, and his kingdom was seized by Saladin (Salah ed-Din), a man of Kurdish origin, who had previously distinguished himself by capturing Egypt in company with Shirkuh, the general of Nurreddin. Saladin almost immediately set himself to drive the Franks from the country. The Frankish king was the boy Baldwin IV., who had paid for the errors of his fathers by being afflicted with leprosy. After being defeated by Saladin at Banias, the Franks were compelled to make a treaty with the Moslem leader. The treaty was broken, and Saladin proceeded to take action. The wretched leper king meanwhile died, his successor, Baldwin V. also a young boy, was poison, and the kingdom passed to the worthless Guy de Lusignan, who in the following year (1187) was crushed by Saladin at the battle of Hattin, which restored the whole of Palestine to the Moslems.

The Third Crusade (1189) to recover Jerusalem was led by Frederick I. of Germany. Acre was captured, but quarrels among the chiefs of the expedition made the enterprise ineffective. It was in this crusade that Richard Coeur-de-lion was especially distinguished among the Frankish warriors.

Saladin died in 1193. In 1204 and 1204 took place the Fourth and Fifth Crusades—mere expeditions, as abortive as the third. And as though it were foreordained that no element of horror should be wanting from the history of the crusades, in 1222 there took place one of the most ghastly tragedies that has ever happened in the world—the Crusade of the Children. Fifty thousand boys and girls were persuaded by some pellucid dreamers that their childish innocence would effect what their immoral fathers had failed to accomplish, and so left their homes on an expedition to capture the Holy Land. The vastly never returned; the happiest of them were shipwrecked and drowned in the Mediterranean. This event is of some historical importance in that it indicates how obvious to their contemporaries the evil character of those engaged in the more serious expeditions. 1

The other four crusades which took place from time to time down to 1272 are of no special importance, though there is a certain amount of interest in the fact that after the sixth crusade, in 1229, emperor Frederick II. was permitted to occupy Jerusalem for ten years. But a new element, the Mongolians of Central Asia, now bursts in on the scene. The tribes from east of the Caspian had conquered Persia in 1218. They were driven westward by pressure of the Tatars, and in 1228 had been called by the ruler of Damascus to his aid. In 1240, however, they transferred their alliance to the sultan of Egypt, and pillaged Northern Syria. Driven downward through Galilee they seized Jerusalem, massacred its inhabitants and plundered its churches. They then marched on to Gaza, where the Egyptians joined them, and together inflicted a crushing defeat on the Christians and Moslems of Syria, for once compelled to unite by the common danger. The Khwarizmians and Egyptians afterwards quarreled, and the former were compelled to retire, leaving Palestine under the rule of the Mameluks 2 sultans of Egypt. Shortly afterwards however, another Central Asiatic invasion—that of the Tatar tribes, took place. Under their leader Hulagu these tribes came by way of Bagdad, which they captured in 1258, and in 1260 they attacked and captured Damascus and ravaged Syria. Bibars (Beibars, Baibars), general of the Egyptian sultan Kotuz, met and drove them back; and having murdered his master, became sultan in his stead. He then proceeded to attack and destroy the relics of Christian possession in Palestine. One after another—Caesarea, Safed, Jaffa, Antioch—they fell, leaving at last Acre (Akka) only. Bibars died in 1277, and in 1291 Acre itself was captured by Khatel son of Kala'un, who thus put an end to Frankish domination.

During the 14th century there is little interest in the history of Palestine. The Christians made efforts to creep back to the promised land, possession, however, being held by Mameluks, the Egyptians, and then by the Franks, who were expelled by Solomon I. of Jerusalem, 1260. The Mameluks finally took possession of the country, and until the days of the Ottoman sultan Selim I. (1520), the occupation of Jerusalem by the Franks was but a memory.

The last stage of the history of Palestine was reached in 1516, when the war between the Ottoman sultan and the Mameluks of Egypt resulted in the transference of the country to the dominion of the Turks. This change of rulers did not produce much change in the administration or condition of the country. Local governors were appointed from headquarters: revenues were annually sent to Constantinople: various public works were undertaken, such as the

1 This story is probably the historic basis of the legend of the "priest Piper of Hamelin."

2 The Mameluks were originally military slaves, who in Egypt succeeded in seizing the supreme power. See Egypt: History (Moslem period).
rebuilding of the walls of Jerusalem by Suleiman the Magnificent (1537): but on the whole Palestine ceases for nearly three hundred years from this point to have a history, save the dreary record of the sanguinary quarrels of local sheiks and of oppression of the peasants by the various government officials. Few or events stand out in the history of this period: perhaps the most interesting personality is that of the Druse prince Fakhrr ud-Din (1595-1634), whose expulsion of the Arabs from the coast as far south as Acre and establishment of his own kingdom, in defiance of Ottoman authority—to say nothing of his dillitante cultivation of art, the result of a temporary sojourn in Italy—make him worth a passing notice. The German botanist, Leonhard Rauwolf (d. 1596 or 1606), who visited Palestine in 1575, has left a vivid description of the difficulties that then beset even so simple a journey as that from Jaffa to Jerusalem. The former town he found in ruins. A safe conduct had to be obtained from the governor of Ramleh before the party could proceed. At Yazur they were stopped by an official who extorted heavy blackmail on the ground that the sultan had given him charge of the "holy places" and had forbidden him to admit anyone to them without payment (!). Further on they had a scuffle with certain "Arabians"; and at last, after successfully accomplishing the passage of the "rough and stony" road that led to Jerusalem, they were obliged to dismount before the gate of the city till they should receive license from the governor to enter.

Towards the end of the 18th century a chief of the family of Zaidan, named Dhafer el-Amir, rose to power in Acre. To him fled from Egypt an Albanian slave named Ahmed, who (from the expertise with which he had been wont to carry out his master's orders to get rid of inconvenient rivals) bore the surname el-Jazzar, "the butcher." He had, however, incurred punishment for refusing to obey a command of his master, Mohammed Bey, and so took refuge with the Palestinian sheik. After five years Mohammed Bey died and el-Jazzar returned to Egypt. Dhafer revolted against the Turkish government and el-Jazzar was commissioned to quell the rising; his long residence with Dhafer having given him knowledge which marked him out as the most suitable for the purpose. He was successful in his enterprise, and was installed as governor in Dhafer's place. He was a man of barbaric aesthetic tastes, and Acre owes some of its public buildings to him: but he was also capricious and tyrannical, and well lived up to his surname. Till 1791 the French had had factories and business establishments at Acre; el-Jazzar ordered them in that year summarily to leave the town. In 1798 Napoleon, returning from his unsuccessful attempt of founding an empire on the Nile, came to stir up a Syrian rising against the Turkish authorities. He attacked el-Jazzar in Acre, after capturing Jaffa, Ramleh and Lydd. A detachment of troops was sent under General Jean Baptiste Kléber across the plain of Esdraelon to take Nazareth and Tiberias, and defeated the Arabs between Fuleh and Afuleh. Napoleon was however compelled by the English to raise the siege. El-Jazzar died in 1806 and was succeeded by his milder adopted son, Sueleiman, who, on his death in 1814 was followed by the fanatic Abdullah. This bigoted Moslem caused the Jewish secretary of his office to be murdered. The Jew had anticipated just such an event, and had secretly arranged that after his death an inventory of Abdullah's property should fall into the hands of the government—knowing that the latter had claims on the estates of el-Jazzar and Sueleiman. The government accordingly pressed their claims: Abdullah refused to pay and was besieged in Acre. He called for the intervention of Mehmet Ali, governor of Egypt; the latter settled the dispute, but Abdullah then refused to discharge the claims of Mehmet Ali. The latter accordingly sent 20,000 men under the command of his son Ibrahim Pasha, who besieged Acre in 1831 and entered and plundered it. So began the short-lived Egyptian domination of Palestine. Mehmet Ali proved no less a tyrannical master than the Turks and the sheiks; the country revolted in 1834, but the insurrection was quelled. In 1840 Lebanon revolted; and in the same year the Turks, with the aid of France, England and Austria, regained Palestine and expelled the Egyptians.

From 1850 onwards the Ottoman government gradually strengthened its hold on Palestine. The power of the local sheiks was step by step reduced, till it at last became evanescent—to the unmixxed advantage of the whole country; and the increase of European interests has led to the establishment of consulates and vice-consulates of the great powers in Jerusalem and in the ports.

The battle of religions still continued. In 1847 the dispute in the Church of the Nativity at Bethlehem about the right to mark with a star the birthplace of Christ became one of the prime causes of the Crimean war. In 1860 occurred a sudden anti-Christian outbreak in Damascus and the Lebanon, in which 14,000 Christians were massacred. On the other hand it may be mentioned that on the 30th of June 1855 the cross was for the first time since the crusades borne aloft through the streets of Jerusalem on the occasion of the visit of a European prince; and that in 1858 the sacred area of the Haramesh-Sherif—the mosque on the site of the Temple of Jerusalem—was for the first time thrown open to Christian visitors. The latter half of the 19th century is mainly occupied with the record of a very restless, unstable process of colonization and settlement—French and Russian monastic and other establishments, some of them semi-religious and semi-political; German colonies; fanatical American communities; Jewish agricultural settlements—all, so to speak, "nibbling" at the country, and each so intent upon gaining a step on its rivals as to be forgetful of the gathering storm. For in the background of all is the vast peninsula of Arabia, which at long intervals fills with its wild, untameable humanity to a point beyond which it cannot support them. This has been the origin of the long succession of Semitic waves—Babylonian, Assyrian, Canaanite, Hebrew, Nabataean, Moslem—that have flowed over Mesopotamia and Palestine; there is every reason to suppose that they will be followed by others, and that the Arab will remain master at the end, as he was in the beginning.

In 1896 Herzl (q.v.) issued his proposal for the establishment of a Jewish state in Palestine and in 1898 he came to the country to investigate its possibilities. The same year was signalized by the picturesque visit of the German emperor, William II., which gave a great stimulus to German interests in the Holy Land.

In 1902 Palestine was devastated by a severe epidemic of cholera. In 1906 arose a dispute between the British and Turkish governments about the boundary between Turkish and Egyptian territory, as the Turks had interfered with some of the landmarks. A joint commission was appointed, which marked out the boundary from Rafah, about midway between Gaza and El-Arish, in an almost straight line S.S.W. to Tabah in 29° 30' on the west side of the gulf of Akaba. A map of the boundary will be found in the Geographical Journal (1907), xxix. 88.

2. The Holy Places.—To the vast majority of civilized humanity, Jewish, Christian and Moslem, the religious interest of the associations of Palestine predominates over every other, and at all ages has attracted pilgrims to its shrines. We need not here do more than allude to the centralization of Jewish ideas and aspirations in Jerusalem, especially in the holy rock on which tradition (and probably textual corruption) have placed the scene of Abraham's sacrifice of Isaac, and over which the Most Holy Place of the Temple stood. The same associations are those of the Moslem, whose religion has so strangely absorbed the prophets and traditions of the older faiths. Other shrines, such as the alleged tomb of Moses, and the mosque of Hebron over the cave of Machpelah, are the centres of Moslem pilgrimage. Christianity is however responsible for the greatest development of the cult of holy places, and it is to the sacred shrines of christendom that we propose to confine our attention.
There is no evidence that the earliest Christians were imbued with the archaeological spirit that interested itself in sites which the Risen Lord had vacated. The site of Golgotha and of the the Holy Sepulchre, of the manger or of the home at Bethany, were to them of no special moment in comparison with the one all-important fact that "Christ was risen." It was not till the clear-cut impress of the events of Christ's life, death and resurrection had with the lapse of years faded from human recollection, that there arose a desire to "seek the living among the dead." The story begins with Helena, mother of Constantine the Great, who became fired with zeal to fix definitely the spots where the great events of Christianity had taken place, and in A.D. 326 visited Palestine for the purpose.

Helena's pilgrimage was, as might be expected, attended with complete success. The True Cross was discovered; and by excavation conducted under Constantine's auspices, the Holy Sepulchre, "contrary to all expectation" as Eusebius distinctly says, was discovered also (see Jerusalem; and Sepulchre, The Holy). The seed thus sown rapidly germinated and multiplied. The stream of pilgrimage to the Holy Land began immediately, and has been flowing ever since. Onwards from A.D. 333, when an anonymous pilgrim from Bordeaux visited the "holy places" and left a succinct account of his route and of the sights which came under his notice, we possess a continuous chain of testimony written by pilgrims relating what they heard and saw.

It is a pathetic record. No site, no legend, is too impossible for the unquestioning faith of these simple-minded men and women. And by comparing one record with another, we can follow the multiplication of "holy places," and sometimes can even see them being shifted from one spot to another, as the centuries pass. Not one of these devout souls had any shadow of suspicion that, except natural features (such as the Mount of Olives, the Jordan, Ebal, Gerizim, &c.) and possibly a very few individual sites (such as Jacob's well at Shechem), there was not a single spot in the whole elaborate system that could show even the flimsiest evidence of authenticity! The growth and development of "holy sites" can best be illustrated, in an article like the present, by a few figures. The account of the "holy places" seen in Palestine by the Bordeaux pilgrim, just mentioned, occupies twelve pages in the translation of the Palestine Pilgrims' Text Society (in whose publications the records of these early travellers can most conveniently be studied); and those twelve pages may be reduced to seven or eight as they are printed with wide margins, and have many footnotes added by the editor. On the other hand the experiences and observations of Felix Fabri, a Dominican monk who visited Palestine about A.D. 1508, occupies in the same series two large volumes of over 600 pages each!1

This process of development has been illustrated in our own time—a single instance will suffice. In the so-called "Via Dolorosa" is a cave which was opened and planned about 1870. It subsequently became closed and forgotten, houses covering its entrance. In 1906 it was re-opened, the houses being cleared away, and a hospice for Greek pilgrims erected in place of them. During these works some local archaeologists attempted to penetrate the cave but were driven away by the labourers with curses. At last the hospice was finished and the cave opened for inspection. A pair of stocks was then shown beautifully cut in the rock, where no stocks appeared in the plan of 1870; with a crude painting suspended on the wall above, blasphemously representing the Messiah confined in them!2

The principal ecclesiastical custodians of the "holy places" by Pope Gregory IX. Certain sites have, however, always been held by the Oriental sects, and since 1868, when the Holy Sepulchre church was destroyed by fire, the number of these has greatly increased. Indeed the 19th century was disgraced, in Palestine, by a feverish "scramble" for sacred sites, in which the most rudimentary ethics of Christianity were forgotten. In the all-mastering desire to oust rival sects and orders Briskus, fraud; even violence, have in turn been employed to serve the end in view: and churches, chapels and monasteries, most of them in the worst architectural taste, have sprung up like mushrooms over the surface of the country, and are perpetuating the memory of pseudo-sanctuaries which from every point of view were best relegated to oblivion.

The zeal and self-sacrificing devotion which some of these establishments, and their inmates, display, and their noble labours on behalf of the country, its people and its history throw into yet more painful relief the actions and attitudes of some of their fellow-Christians.

The authenticity of the "holy places" was first attacked seriously in the 18th century by a bookseller of Altona named Korte; and since he led the way, a steady fire of criticism has been poured at this huge mass of invention. The process of manufacturing new sites, however, continues unchecked. Even the Protestant churches are not exempt from blame in the matter; a small tomb near the Damascus Gate of Jerusalem has been fixed upon by a number of English enthusiasts as the true "Holy Sepulchre," an identification for which there is nothing to be said.

The monasteries of the Roman communion and their residents were under French protection until the disturbance between Greek and Franciscan monks in the Holy Sepulchre church (Nov. 4, 1901), which arose over the question as to the right to sweep a certain flight of stairs. Stones and other weapons were freely used, and several of the combatants and bystanders were seriously injured. As one result of the subsequent investigations, Latin monks of other countries were assigned to the protection of the consuls of those countries.

5. Colonization.—Down to the time of Mehemet Ali the only foreigners permanently resident in the country were the members of various missionary orders, and a few traders, such as the French merchants of Acre. The first protestant missionaries (those under the London Society for the Promotion of Christianity among the Jews), settled in Jerusalem in 1823; to them is due the inception of the trade in olive-wood articles, invented for the support of their converts. In 1846–1848 a remarkable religious brotherhood (the Brüderhaus, founded by Spittler of Basel) settled in Jerusalem: it was originally intended to be a settlement of celibate mechanics that would form a nucleus of mission work to evangelize the world. One of this community was Dr C. Schick, who lived over 50 years in Jerusalem, and made many valuable contributions to its archaeology. In 1849 came the first of several examples that have appeared in Palestine from time to time of that curious product of American religious life—a community of dupes or visionaries led by a prophet or prophetess with claims to divine guidance. The leader in this case was one Mrs Minor, who, came to prepare the land for the expected Second Advent. Her followers quarrelled and separated in 1853. This event is of importance, as it had much to do with the remarkable development of Jewish colonization which is a special feature of the latter part of the history of the 19th century in Palestine. For Mrs Minor, having an interest in the Jewish people, was befriended by Sir Moses Montefiore; after her death her property was placed in charge of a Jew, and later passed into the hands of the Alliance Israélite Universelle.

This body in 1870 established an agricultural colony for Jews on the road from Jaffa to Jerusalem ("Mikweh Israel").

Another visionary American colony, led by a certain Adams, came in 1866. They brought with them framed houses from America, which are still standing at Jaffa. But the Adamsites suffered from disease and poverty, and lost heart in a couple of years. Returning to America, they sold their property to a German community, the Tempelgemeinde, a Unitarian sect led by Messrs Hofmann and Hardweg who established themselves in Jaffa in 1868. Unlike the ill-fated American communities, these hearty Württemberg peasants have flourished in Palestine, and their three colonies—at Jaffa, Haifa, and Jerusalem—are the most important European communities now in the country.
Since 1870 there has been a steady development of Jewish immigration, consisting principally of refugees from countries where Anti-Semitism is an hopeless element. To public work, Rina de Rothschild has invested large sums in Jewish colonies, but at the commencement of the present century he handed over their administration to the Jewish Colonization Association. Time alone can show how far these colonies are likely to be permanently successful, or how the subtly enervating influence of the climate will affect later generations.

4. Exploration.—Previous to the 19th century the turbulent condition of the country made exploration difficult, and, off the beaten track, impossible. There are many books written by early pilgrims and by more secular travellers who visited the country, which—when they are not devoted to the setting forth of worthless traditions, as is too often the case—give very useful and interesting pictures of the conditions of life and of travel in the country. Scientific exploration does not begin before Edward Robinson, an American clergyman, who, after devoting many years to study to fit himself for the work, made a series of journeys through the country, and under the title of Biblical Researches in Palestine (1831—1838) published his itineraries and observations. His work is marred by the hastiness of his visits and consequent superficiality of his descriptions of sites, and by some rash and untenable identifications: but it is at once a standard and the foundation of all subsequent topographical work in the country. He was worthily followed by Titus Tobler, who in 1853 and later years published volumes abounding in exact observation; and by V. Guérin, whose Description géographique, historique, et archéologique de la Palestine, in 7 vols. (1868—1880), contains an extraordinary mass of material collected in personal travel throughout the country.

In 1864 was founded the Palestine Exploration Fund, under the auspices of which an ordinance survey map of the country was completed (published 1881), and accompanied by volumes containing memoirs on the topography, oorography, archaeology, fauna and flora, and other details. A similar work east of the Jordan was begun but (1854) by the Ottoman government. The same society initiated the scientific exploration of the mounds of Palestine. In 1891 it excavated Tell el-Hesi (Lachish); in 1896—1898 the south wall of Jerusalem; in 1898—1900 Tell es-Safi (Gath) and some smaller mounds in the Shephelah; all under the direction of Dr F. J. Bliss. In 1902 it began the excavation of Gezer under the direction of R. A. S. Macalister (see GEZER).

The example thus set has been followed by French, German and American explorers. The Deutscher Palästina-Verein was founded in 1878, and under its auspices important surveys have been carried out, especially those of G. Schumacher east of the Jordan; Tell el-Mutesellim (Megiddo) has also been excavated. The Austrian Dr E. Sellin, working independently, has excavated Tell Tu‘n (Taanach), and in 1907 began work upon the mound of Jericho. An admirable biblical and archaeological school, under the control of the Dominican order, exists at Jerusalem; and German and American archaeological institutions, educationally and financially, are sending workers to the field. Thus the scientific exploration is annually done by the directors of these schools and by their pupils. Under this head we must not omit to mention A. Musil's investigations of some remote parts of Eastern Palestine, and R. E. Brünnow's great survey of Petra, with part of Moab and Edom.

BIBLIOGRAPHY.—The literature relating to Palestine is very abundant; see especially, P. Thomsen, Systemat. Bibliog. f. Palästina-Literatur, i., 1805—1904 (Leipzig, 1908). A large collection of names of works will be found in R. Röhrich, Bibliotheca geographica Palaestinae (1890). Older bibliographies are T. Tobler, Bibliogra phia geographica et historica Palestinae (with a supplement by H. A. Petzholdt's Neuer Anzeiger für Bibliographie und Bibliothekwissen schaft) (1878).

TOPOGRAPHY.—C. Ritter, Vergleichende Erdkunde, xv—xviii. (1848—1855); E. Robinson, Biblical Researches in Palestine (1841). Later Biblical Researches (1856), Physical Geography (1856); A. Reland, Palestina monumentum veteribus illustrata (1714); H. B. Tristram, Land of Israel (1865), Land of Moab (1873); The Palestine Exploration Fund, map and companion volumes (Memoirs of the Survey of Western Palestine), 7 vols.; S. Merrill, East of the Jordan (1881); T. Tobler, Bethleem (1849), Nazareth (1868), Dritte Wanderung (1899); C. R. Conder, Tent Work in Palestine (1878); G. Schumacher, Geschichte des jüdischen Volkes im Zeitalter Jesu Christi (3rd ed., 1885); S. Merrill, Galilee in the time of Christ (1885); W. Besant and E. H. Palmer, Jerusalem (2nd ed., 1903), Jerusalem and its Environs, 1097—1201 (ed. R. Röhrich, 1893, 1904); R. Röhrich, Geschichte der Kreuzzüge (1898); B. von Kugler, Geschichte der Kreuzzüge (1897); C. PALESTINE, a city and the county-seat of Anderson county, Texas, U.S.A., about 90 m. E. by N. of Waco. Pop. (1910 census) 10,482. It is served by two lines of the International & Great Northern railway, and by the Texas State railway. Palestine is the trade centre of a district which produces cotton, timber, fruit (especially peaches), an excellent grade of tobacco, petroleum, iron-ore and salt. It has various manufactu res, including cotton gins, cotton-seed oil, cigars, lumber and brick. Its factory products were valued at $735,162 in 1905. About 2 m. south-west of Palestine a settlement (the first in the present Anderson county) was made in 1837, and there Fort Houston, a stockade fort, was built to protect the settlers from the Indians. Palestine was laid out and was
made the county-seat in 1846; it was chartered as a city in 1875, and rechartered in 1905. In 1909 it adopted a commission government.

PALESTRINA, GIOVANNI PIERLUIGI DA (1525-1594), Italian composer, was born in Palestrina (the ancient Praeneste) at the foot of the Sabine mountains, in 1525. The various versions of his name make an interesting record. He appears as Palestrina, Pellestrino, Gio. Palestina, Gianetto Palestrina, Gianetto da Palestrina, Gian Pier. de Palestrina, Joh. Petrus Aloisius, Jo. Petraloys, Gianetto, Givc. Prenestini, Joannes Prenestinus, Joannes Petraloysius Prenestinus.

Palestrina seems to have been at Rome from 1540 to 1544, when he studied possibly under Gaudio Mellis, but not under Guidimel as has erroneously been assumed. On the 12th of June 1547 he married Lucrezia de Goris. In 1551, by favour of Pope Julius III, he was elected Magister Cappellae and Magister Puerorum at the Cappella Giulia, S. Pietro in Vaticano, with a salary of six scudi per month, and a house. Three years later he published his First Book of Masses, dedicated to Pope Julius III, and beginning with the missa " Ecce saceros magna." On the 14th of January 1555, Palestrina was enrolled, by command of Pope Julius III, among the singers of the Cappella Sistina. This honour involved the resignation of his office at the Cappella Giulia, which was accordingly bestowed upon his friend Animuccia. But the legality of the new appointment was disputed on the ground that Palestrina was married, and the father of four children, his wife, Lucrezia, being still alive; and, though, for the moment, the pope's will was law, the case assumed a different complexion after his death, which took place only five weeks afterwards. The next pope, Marcellus II., was succeeded after a reign of 23 days, by Paul IV.; and within less than a year (July 30, 1555) that stern reformer dismissed Palestrina, together with two other married singers, A. Ferrabosco and Bari, with a consolatory pension of six scudi per month to each. This cruel disappointment caused Palestrina a dangerous illness; but in October 1555 he was appointed maestro di cappella at the Lateran, without forfeiting his pension; and in February 1556 he exchanged this preferment for a similar one, with an allowance of 16 scudi per month, at Santa Maria Maggiore.

Palestrina remained in office at this celebrated basilica for ten years, and to this period is assigned an important chapter in the history of music. Many circumstantial details of this chapter are undoubtedly legends, due to the pious imagination of Baini and others. In 1562 the council of Trent censured the prevalent style of ecclesiastical music with extreme severity. In 1564 Pope Pius IV. commissioned eight cardinals to investigate the causes of complaint; and these proved to be so well founded that it was seriously proposed to forbid the use of all music in the services of the Church, except unisonous and unaccompanied plain-chant. In these circumstances Palestrina is said to have been invited by two of the most active members of the commission to come to the rescue. He accordingly prepared a scheme of liturgical composition, so altogether different from the licentious procedure hitherto prevailing. These were privately rehearsed, in presence of the commissioners, at the palace of Cardinal Vitellezzi; and the judges were unanimous in deciding that the third mass filled, in the highest possible degree, all the conditions demanded. The private trial took place in June 1565, and on the 19th of that month the mass was publicly sung at the Sistine Chapel, in presence of Pope Pius IV., who compared its music to that heard by St John in his vision of the New Jerusalem. Parvi transcribed it, for the library of the choir, in characters of extraordinary size and beauty; and Palestrina was appointed by the pope composer to the Sistine Chapel, an office created expressly in his honour and confirmed to him by seven latter pontiffs, though with the very insufficient honorarium of three scudi per month, in addition to the six which formed his pension.

In 1567 this mass was printed in Palestrina's Liber secundus missarum. The volume was dedicated to Philip II. of Spain, but the mass was called the Missa Papae Marcelli. This title, clearly given in honour of the short-lived pope Marcellus II., has given rise to an absurd story, told by Pellegrini and others, to the effect that the mass was composed by Pope Marcellus II., martyred early in the 4th century, and was only discovered by Palestrina. Of course in the 4th century such music was inconceivable. The Missa Papae Marcelli is now almost certainly known to have been composed in 1562, two years before Paul IV.'s commission. Its ineffable beauty had often been described in glowing terms by those who heard it in the Sistine Chapel, but it was only first heard in England in 1822, when the Bach choir, consisting of 200 unaccompanied voices, sang it at St James's Hall, under the direction of Mr Otto Goldschmidt.

Upon the death of Animuccia in 1571 Palestrina was re-elected to his appointment at the Cappella Giulia. He also succeeded Animuccia as maestro di cappella at the oratory of Philip Neri; but these appointments were far from lucrative, and he still remained a very poor man. A letter of thanks for 100 scudi, written on the 21st of March 1579 to the duke of Mantua, illustrates this situation. In 1580 he was much distressed by the death of his wife; and the loss of three promising sons, Angelo, Ridolfo and Silla, left him with one child only—Ignazio, a very unworthy descendant. In February 1587 he married the rich widow Virginia Dormuli. In 1586 Pope Sixtus V. wished to appoint him maestro to the pontifical choir, as successor to Antonio Boccapadule, then about to resign, and commissioned Boccapadule to prepare the choir for the change. Boccapadule, however, managed so clumsily that Palestrina was accused of having mainly plotted for his own advancement. The Pope was very angry, and punished the calumniators very severely; but Palestrina lost the appointment. These troubles, however, did not hinder his work, which he continued without intermission until the end of February 1594, when he breathed his last in the arms of his friend, Filippo Neri. (W. S. R.)

In the articles, Music, Counterpoint, Contrapuntal Forms, Harmony, Mass, Motet, and that portion of Instrumentation which deals with vocal music, the reader will find information as to many features of Palestrina's style and its relation to that of the 16th century in general. So simple are the materials of 16th-century music, and so close its limitations, that the difference between great and small artists, and still more the difference between one great artist and another, can be detected only by long and familiar experience. A great artist, working within limits so narrow and yet so natural, is fortunately apt to give us exceptional opportunities for acquiring the right kind of experience of his art, since his genius becomes far more prolific than a genius with a wider field for its energies. Yet all 16th-century masters seem to be illuminated by the infallibility of the normal musical technique of their time. This technique is no longer so familiar to us that its euphony and vivid tone can fail to impress us wherever we meet it. There is probably no respectable school piece of the 16th century, which, if properly performed in a Roman Catholic church, would be quickly distinguishable by ear from the style of Palestrina. But when we find that every addition to our acquaintance with Palestrina's work is something which is unique, having no parallel in the music of other men, that indicates that he has made possible the results of 16th-century music, but to our whole sense of style, we may then recognize that we are in the presence of one of the greatest artists of all time.

Palestrina's work has many styles. Within its narrow range there can be no such glaring contrasts as those of the "three styles" of Beethoven; yet the distinctions are as real as they are delicate. His early, or Flemish style, was apt to lead him into the notorious Flemish disregard of proportion. Yet in some of his greatest works, such as the Missa brevis, we find unmistakably Flemish features so idealized as to produce breadth of phrase (Missa brevis, Agnus Dei), remarkably modern firmness of form (ibid. second Kyrie), and close canonie sequence carried to surprising length resulting in natural unexpectedness of harmony and subtle swing of cross rhythm (Amen of Credo).

If we find it convenient to divide Palestrina's work roughly into three types, we shall be able to take the Missa Papae Marcelli as the crowning representative of his second style. It probably is his greatest work; at all events it continues to make
that impression whenever it is read after a long course of his other works; yet there are many masses, too numerous to mention, which cannot easily be considered inferior to it. Indeed F. X. Haberl, the editor of the complete critical edition of Palestrina's works, prefers the Missa Ecce ego Joannes, first published by him in the 24th volume of that edition in 1887.

Palestrina-scholars will hardly think us singular for placing on the same plane as the Missa Papae Marcelli at least 16 out of Palestrina's 94 extant masses: Missa brevis, bk. 3, no. 3; Dies sanctificatus, bk. 6, no. 1; Dilexi quomiam, bk. 6, no. 5; O admirabile commercium, bk. 8, no. 3; Dum complurientur, bk. 8, no. 5; Veni sponsa Christi, bk. 9, no. 2; Quinti toni, bk. 10, no. 5; Octavi toni, bk. 11, no. 4; Alma Redemptoris, bk. 11, no. 5; Ascendo ad Patrem, bk. 12, no. 3; Tu es Petrus, bk. 12, no. 5; Hodie Christus natus, cst, bk. 13, no. 2; Beatus Laurentius, bk. 14, vol. 3; Assumpta est Maria, bk. 14, no. 5; Tu es Petrus, bk. 15, no. 5; Ecce ego Joannes, bk. 15, no. 6.

The third and most distinctive phase of Palestrina's style is that in which he relies entirely upon the beauty of simple masses of harmony without any polyphonic elaboration whatever. Sometimes, as in his four-part litanies, this simplicity is mainly a practical necessity; but it is more often used for the purpose of his profoundest expressions of sacramental or penitential devotion, as for instance in the motet Fratres ego enim accepti, the Stabat Mater and the first, really the latest, book of Lamentations.

Besides these three main styles there are numerous cross-currents. There is the interaction between the madrigal and ecclesiastical style, which Palestrina sometimes contrives to show without confusion or degradation, as in the mass Vestiva i colli. There is the style of the madrigali spirituali, including Le Vergine of Petrarca; which again distinguishes itself into a broader and a slighter manner. And there is lastly an astounding absorption of the wildest freaks of Flemish ingenuity into the loftiest polyphonic ecclesiastical style; the great example of which is the Missa L'Homme armé, a work much maligned by writers who know only its title and the part played by its secular theme in medieval music.

The works published in Palestrina's lifetime naturally contain a large proportion of his earlier compositions. After his death the publication of his works continued for some years. We are apt to read the musical history of the 17th century in the light of the works of its composers. But a somewhat different view of that time is suggested by the continual pouring out by influential publishers of posthumous works of Palestrina, in far greater quantities than Palestrina had either the influence or resource to publish in his lifetime. We regard the 17th-century monodists as triumphant iconoclasts; but it was not until their primitive efforts had been buried beneath the entirely new arts to which they led, that the style of Palestrina ceased to be upheld as the one artistic ideal. Moreover the posthumous works of Palestrina belong almost entirely to his latest and finest period; so that a study of Palestrina confined to the works which he himself was able to publish gives no adequate idea of the proportion which his greater works bear to the rest. It was not, then, the rise of monody that crowded 16th-century art out into a long oblivion. On the contrary, the Palestrina tradition was the one thing which gave 17th-century composers a practical basis for their technical training. Only in the 18th century did the new art, before coming to maturity under Bach and Handel, reduce the Palestrina style to a dead language.

In the middle of the 19th century that dead language revived in a renaissance which has steadily spread throughout Europe. The Musica divina of Canon K. Proske of Regensburg, begun in 1853, was perhaps the first decisive step towards the restoration of Roman Catholic church music. The St Cecilia Verein, with Dr F. X. Haberl as its president, has carried on the publication and use of such works with the greatest energy in every civilized country. The difficulties of reintroducing it in its native home, Italy, were so enormous that it is arguable that they might not yet have been surmounted but for the adoption of less purely artistic methods by Don Lorenzo Perosi, who succeeded in crowding the Italian churches by the performance of compositions written in an artless manner which, by its mere negation of display, was fitted to produce upon the unsophisticated listeners such devout impressions as might gradually win them from the taste for theatrical modern church music. The pope's fiat has now inculcated the use of Gregorian and 16th-century church music as far as possible in all Roman Catholic churches, and the effect has been astonishing. Within eighteen months of Pius X.'s decree on church music, the choir of Cologne Cathedral, previously far less accustomed to a pure polyphonic style than most German Protestant choirs, at Easter of 1905 gave a very satisfactory performance of the Missa Papae Marcelli.

The influence of what is henceforth an inevitable and continual familiarity of Palestrina's style, at least among Roman Catholics, cannot fail to have the profoundest effect upon modern musical culture.

Palestrina's works, as contained in the complete edition published by Breitkopf and Härtel, comprise 256 motets in 7 vols., the last two consisting largely of processions hitherto unpublished, with one or two wrongly or doubtfully ascribed to Palestrina; 15 books of masses, of which only 6 were published in Palestrina's lifetime, the 7th being incompletely projected by him, and the 8th and 9th first published; to these 25 motets and 14 masses, 2 books of magnificats, on all the customary tunes; 1 vol. of hymns; 1 vol. (2 books) of offertories for the whole year; a volume containing 3 books of litanies and several 12-part motets; 3 books of Latin madrigals; 3 books of organ fugues; 2 early books and 50 later madrigals collected from mixed publications; 2 books of Madrigali spirituali, and 4 vols. of miscellaneous works, newly discovered, imperfectly preserved and doubtful. The fourth book of motets contains a collection of works written at different times, but a single scheme, being a setting of the Song of Solomon; and the fifth volume is, like the offertories, designed for use throughout the church year.

(D. F. T.)

PALETTO (the Fr. diminutive of pale, spade, blade of an oar, from Lat. pala, spade, baker's shovel or peel; cf. pandere, to spread), a term applied to many objects which are flat and have a specifically to a thin tablet made of porcelain, or other material on which artists place their colour. The term is also used of the shallow box, with partitions for the different coloured tesserae, used by mosaic workers. By transfere the colours which an individual artist employs are known as his "palette." The "palette-knife" is a thin flexible knife used for arranging the colours on the palette, &c., and for the application of colour on the canvas in large masses.

PALEY, FREDERICK APThorp (1815–1888), English classical scholar, was born at Easingwold in Yorkshire on the 14th of January 1815. He was the grandson of William Paley, and was educated at Shrewsbury school and St John's College, Cambridge (B.A. 1838). His conversion to Roman Catholicism forced him to leave Cambridge in 1846, but he returned in 1860 and resumed his work as "coach," until in 1874 he was appointed professor of classical literature at the newly founded Roman Catholic University of Northampton. This institution was closed in 1877 for lack of funds, and Paley removed to Bowesmore, where he died on the 8th of December 1888. His most important editions are: Aeschylus, with Latin notes (1844–1847), the work by which he first attracted attention; Aeschylus (4th ed., 1879), Euripides (2nd ed., 1872), Hesiod (2nd ed., 1883), Homer's Iliad (2nd ed., 1884), Sophocles, Philoctetes, Electra, Trachiniae, Ajax (1880)—all with English commentary and forming part of the Bibliotheca classica; select private orations of Demostenes (3rd ed., 1896–1898); Theocritus (2nd ed., 1886), with brief Latin notes, one of the best of his minor works. He possessed considerable knowledge of architecture, and published a Manual of Gothic Architecture (1846) and Manual of Gothic Gouldings (5th ed., 1902).

PALEY, WILLIAM (1743–1805), English divine and philoso-pher, was born at Peterborough. He was educated at Giggles-wick and Peterhouse, Cambridge, became fellow of Pembroke College, Cambridge. He graduated in 1766, was student, and in 1768 tutor of his college. He lectured on Clarke, Butler and Locke, and also delivered a systematic course on moral philosophy, which subsequently formed the basis of his well-known treatise. The treatment
PALGRAVE—PALGRAVE, SIR F. 629

controversy was then agitating the university, and Paley published an anonymous "Defence of a pamphlet in which Bishop Law had advocated the reformation and simplification of the Thirty-Nine Articles; he did so, however, sign the petition (called the "Feathers" petition from being signed at a meeting at the Feathers tavern) for a relaxation of the terms of subscription. In 1776 Paley was presented to the rectory of Musgrave in Westmorland, supplemented at the end of the year by the vicarage of Dalston, and presently exchanged for that of Appleby. In 1782 he became archdeacon of Carlisle. At the suggestion of his friend John Law (son of Edward Law, bishop of Carlisle and formerly his colleague at Cambridge), Paley published (1785) his lectures, revised and enlarged, under the title of The Principles of Moral and Political Philosophy. The book at once became the ethical textbook of the University of Cambridge, and passed through fifteen editions in the author’s lifetime. He strenuously supported the abolition of the slave trade, and in 1789 wrote a paper on the subject. The Principles was followed in 1790 by his first essay in the field of Christian apologetics, The Life of Paulinae, or the Truth of the Scripture History of St Paul vindicated from the Falsity of the Epistles which bear his Name with the Acts of the Apostles. This and his other writings were praised, probably the most original of his author’s works. It was followed in 1794 by the celebrated View of the Evidences of Christianity. Paley’s latitudinarian views are said to have debarred him from the highest positions in the Church. But for his services in the defense of the faith the bishop of London gave him a stall in St Paul’s; the bishop of Lincoln made him subdean of that cathedral, and the bishop of Durham conferred upon him the rectory of Bishopwearmouth. During the remainder of his life his time was divided between Bishopwearmouth and Lincoln. In 1802 he published Natural Theology, or Evidences of the Existence and Attributes of the Deity collected from the Appearances of Nature, his last, and, in some respects, his most remarkable book. In this he endeavoured, as he says in the dedication to the bishop of Durham, to repair in the study his deficiencies in the church. He died on the 29th of May 1805.

In the dedication just referred to, Paley claims a systematic unity for his works. It is true that “they have been written in an order the very reverse of that in which they ought to be read”; nevertheless the Natural Theology forms the completion of a regular series. His purpose is to demonstrate the truth of the Deity, and it is apparent if it is considered that the Moral and Political Philosophy admits two presuppositions: (1) that “God Almighty wills and wishes the happiness of His creatures”, and (2) that adequate provision has been made for future rewards and punishments. Now the second presupposition does, according to Paley, on the credibility of the Christian religion (which he treats almost exclusively as the revelation of these “new sanctions” of morality). The Evidences and the Horae Paulinae were intended as a demonstration of this belief. The argument of these books, however, depends in turn upon the assumption of a benevolent Creator desirous of communicating with His creatures for their good; and the Natural Theology, by applying the argument from the existence of a Deity, becomes the foundation of the argumentative edifice.

In his Natural Theology Paley has adapted with consummate skill the argument which Ray (1651) and Derham (1711) and Niebuhr (1742) carried into the town of modern philosophy. The argument of these books, however, depends in turn upon the assumption of a benevolent Creator desirous of communicating with His creatures for their good; and the Natural Theology, by applying the argument from the existence of a Deity, becomes the foundation of the argumentative edifice.

But the illustration is not peculiar to Paley, and had been appropriated by many others before Paley. The germ of the idea is to be found in Cicero, De natura deorum, ii. 34 (see Hallam, Literature of Europe, i. 385, note). In the case of a writer whose chief merit is the way in which he has worked up existing material, a general charge of plagiarism is almost irrelevant.

1 Bernard Nieuwentyt (1654–1718) was a Dutch disciple of Descartes, whose work, Regi guarum der Weltz Beschouwingen, published in 1716, was translated into English in 1730 by J. Chamberlayne under the title of The Religious Philosopher. A charge of wholesale plagiarism against this book was brought against Paley in the Athenaeum for 1848. Paley refers several times to Nieuwentyt, who uses the famous illustration of the watch. But the illustration is not peculiar to Nieuwentyt, and had been appropriated by many others before Paley. The germ of the idea is to be found in Cicero, De natura deorum, ii. 34 (see Hallam, Literature of European, i. 385, note). In the case of a writer whose chief merit is the way in which he has worked up existing material, a general charge of plagiarism is almost irrelevant.
PALGRAVE, F. T.—Pali

to a firm of solicitors, but was called to the bar at the Middle Temple in 1827. On his marriage in 1823 with Elizabeth, daughter of Dawson Turner of Great Yarmouth, he had become a Christian, and had changed his name to Palgrave, the maiden name of his wife's mother. His work as a barrister was chiefly concerned with pedigree cases before the House of Lords. He edited for the Record Commission Parliamentary Writs (London, 1827-1834); Rotuli curiae regis (London, 1835); The antient calendars and inventories of the treasury of his majesty's exchequer (London, 1836); and Documents and records illustrating the history of Scotland (London, 1837), which contains an elaborate introduction. In 1831 he published his History of England, Anglo-Saxon Period, later editions of which were published as History of the Anglo-Saxons; in 1832, his Rise and Progress of the English Commonwealth, pronounced by Freeman a "memorable book"; and in 1834 his Essay upon the original authority of the king's courts. He was knighted, and after becoming a fellow of the municipal corporations commissioners, became deputy-keeper of the public records in 1838, holding this office until his death at Hampstead on the 6th of July 1861. Palgrave's most important work is his History of Normandy and England, which appeared in four volumes (London 1851-1864), and deals with the history of the two countries down to 1102.

He also wrote Truths and Fictions of the Middle Ages (London, 1837, and again 1844); The Lord and the Vassal (London, 1844); and Travellers in Northern Ireland (London, 1842, and subsequent editions).

Palgrave's four sons were: Francis Turner Palgrave (q.v.), sometime professor of poetry at Oxford; William Gifford Palgrave; Sir Robert Harry Inglis Palgrave (b. 1827), an authority upon banking and economics generally; and Sir Reginald Francis Douce Palgrave.

William Gifford Palgrave (1826-1888) went to India as a soldier after a brilliant career at Charterhouse School and Trinity College, Oxford; but, having become a Roman Catholic, he was ordained as a Jesuit missionary in India, and spent time in India, Syria, and Arabia. Forsaking the priesthood about 1864, he was employed as a diplomatist by the British government in Egypt, Asia Minor, the West Indies, and Bulgaria, being appointed resident minister in Uruguay in 1884; he died at Montevideo on the 30th of September 1888. He wrote a romance, Herrmann Agha (London, 1872), A Narrative of a Year's Journey through Central and Eastern Arabia (London, 1865), Essays on Eastern Questions (London, 1872), and other works.

Sir Reginald Palgrave (1829-1904) became a solicitor in 1851; but two years later was appointed a clerk in the House of Commons, becoming clerk of the House on the retirement of Sir Erskine May in 1886. He was made a K.C.B. in 1892, retired from his office in 1900, and died at Salisbury on the 13th of July 1902. Sir Reginald was the editor of The House of Commons: Illustrations of its History and Practice (London, 1869); and Cromwell: an appreciation based on contemporary evidence (London, 1890). He also assisted to edit the tenth edition of Erskine May's Law, Privileges, Proceedings and Usage of Parliament (London, 1890).

Palgrave, Francis Turner (1824-1897), English critic and poet, eldest son of Sir Francis Palgrave, the historian, was born at Great Yarmouth, on the 28th of September 1824. His childhood was spent at Yarmouth and at his father's house in Hampstead. At fourteen he was sent as a day-boy to Charterhouse; and in 1843, having in the meanwhile travelled extensively in Italy and other parts of the continent, he proceeded to Oxford, having won a scholarship at Balliol. In 1846 he interrupted his university career to serve as assistant private secretary to Gladstone, but returned to Oxford the next year, and took a first class in Literae Humaniores. From 1847 to 1862 he was fellow of Exeter College, and in 1850 entered the Education Department at Whitehall. In 1850 he accepted the vice-principalship of Kneller Hall Training College at Twickenham. There he came into contact with Tennison, and laid the foundation of a lifelong friendship. When the training college was abandoned, Palgrave returned to Whitehall in 1855, becoming examiner in the Education Department, and eventually assistant secretary. He married, in 1862, Cecil Grenville Milnes, daughter of James Milnes-Gaskell. In 1884 he resigned his position at the Education Department, and in the following year succeeded John Campbell Shairp as professor of poetry at Oxford. He died in London on the 24th of October 1897, and was buried in the cemetery on Barnes Common. Palgrave published both criticism and poetry, but his work as a critic was by far the more important. His Visions of England (1880-1881) has dignity and lucidity, but little of the "natural magic" which the greatest of his predecessors in the Oxford chair considered rightly to be the test of inspiration. His last volume of poetry, Amenophis, appeared in 1892. On the other hand, his criticism was always marked by fine and sensitive tact, quick intuitive perception, and generally sound judgment. His Handbook to the Fine Arts Collections, International Exhibition, 1883, and his Essays on Art (1866), though not free from dogmatism and over-enthusiasm, were sincere contributions to art criticism, full of striking judgments strikingly expressed. His Landscape in Poetry (1897) showed wide knowledge and critical appreciation of one of the most attractive aspects of poetic interpretation. But Palgrave's principal contribution to the development of literary taste was contained in his Golden Treasury of English Songs and Lyrics (1861), an anthology of the best poetry in the language constructed upon a plan sound and spacious, and followed out with a delicacy of feeling which could scarcely be surpassed. Palgrave followed it with a Treasury of Sacred Song (1889), and a second series of the Golden Treasury (1897), including the work of later poets, but in neither of these was quite the same exquisiteness of judgment preserved. Among his other works were The Passionate Pilgrim (1889), a volume of selections from Spenser entitled Chrysolena (1877), a memoir of Clough (1862) and a critical essay on Scott (1856) prefixed to an edition of his poems.

See Gwennan F. Palgrave, F. T. Palgrave (1899).

Pali, the language used in daily intercourse between cultured people in the north of India from the 7th century B.C. It continued to be used throughout India and its confines as a literary language for about a thousand years, and is still, though in a continually decreasing degree, the literary language of Burma, Siam, and Ceylon. Two factors combined to give Pali its importance as one of the few great literary languages of the world: the one political, the other religious. The political factor was the rise during the 7th century B.C. of the Kosala power. Previous to this the Aryan settlements, along the three routes they followed in their penetration into India, had remained isolated, independent and small communities. Their language bore the same relation to the Vedic speech as the various Italian dialects bore to Latin. The welding together of the great Kosala kingdom must have had more than twice the size of England, in the very centre of the settled country, led inescapably but irresistibly to the establishment of a standard of speech, and the standard followed was the language used at the court at Śravathī in the Nepalese hills, the capital of Kosala. When Gotama the Buddha, himself a Kosalan by birth, determined on the use, for the propagation of his religious reforms, of the living tongue of the people, he and his followers naturally made full use of the advantages already gained by the form of speech current through the wide extent of his own country. A result followed somewhat similar to the effect, on the German language, of the Lutheran reformation. When, in the generations after the Buddha's death, his disciples compiled the documents of the faith, the form they adopted became dominant. But local varieties of speech continued to exist.

The etymology of the word Pali is uncertain. It probably means row, line, as in "pali," and is used, in its exact technical sense, of the language of the canon, containing the documents of the Buddhist faith. But when Pali first became known to Europeans it was already used also, by those who wrote in Pali, of the language of the later writings, which bear the same relation to the standard literary Pali of the canonical texts as medieval
The canonical texts are divided into three collections called Pitakas, i.e. baskets. This figure of speech refers, not to a basket or box in which things can be stored, but to the baskets, used in India in excavations, as a means of handing on the earth from one worker to another. The first Pitaka contains, the Vinaya—that is, Rules of the Order; the second, the Suttas, giving the doctrine, and the third, the Abhidhamma, analytical exercises in the psychological system on which the doctrine is based. These have now nearly all, mainly through the work of the Pali Text Society, been published in Pali.

The Vinaya was edited in 5 vols. by H. Oldenberg; and the more important parts of it have been translated into English by Rhys Davids. A complete and annotated translation was published by the Oldenberg Society.

The Sutta Pitaka consists of five Nikāyas, four principal and one supplementary. The four principal ones have been published for the Pali Text Society, and some volumes have been translated into English or German. These four Nikāyas, sixteen volumes in all, are the main authorities for the doctrines of early Buddhism.

The fifth Nikāya is a miscellaneous collection of treatises, mostly very short, on a variety of subjects. It contains lyrical and ballad poetry, specimens of early exegesis and commentary, lives of the saints, collections of edifying anecdotes and of the now well-known Jātakas or Birth Stories. Of these, eleven volumes had by 1910 been edited for the Pali Text Society by various scholars, the fifth being the last. (The twenty volumes of the Bhikṣuṇi Vinaya, devoted to the lives of the nuns, are not included in the Pali Text Society; and one, the Dhamma Sangoṭi, has been translated by Mrs Rhys Davids. A description of the contents of all these books in the canon is given in Rhys Davids's American Lectures, pp. 44-5.)

A certain amount of progress has been made in the historical criticism of these books. Out of the twenty-nine works contained in the three Pitakas only one claims to have an author. That one is the Kathā Vatthu, ascribed to Tissa the son of Moggallāna, who presided over the third council held under Asoka. It is the latest book of the third Pitaka.

All the rest of the canonical works grew up in the schools of the Order, and most of them appear to contain documents, or passages, of different dates. In his masterly analysis of the Vinaya, in the introduction to his edition of the text, Professor Oldenberg has shown that there are at least three strata in the existing presentation of the Rules of the Order, the oldest portions going back probably to the time of the Buddha himself. Professor Rhys Davids has put forward similar views with respect to the Jātakas and the Sutta Nipāta in his Buddhist India, and with respect to the Nikāyas in general in the introduction to his Dialogues of the Buddha. An analysis of the State of Things in Early Buddhism has been attempted in his Mūra und Buddha, and those relating to the Buddha's birth in his Buddha's Geburt. It seems probable that the Vinaya and the four Nikāyas were put substantially into the shape in which we now have them before the council at Vesālī, a hundred years after the Buddha's death; that slight alterations and additions were made in them, and the miscellaneous Nikāya and the Abhidhamma books completed, at various times down to the third council under Asoka; and that the canon was then considered closed. No evidence has yet been found of any alterations made, after that time, in Ceylon; but there were probably before that time, in India, other books, now lost, and other recensions of some of the above.

Of classical Pāli in northern India subsequent to the canon there is but little evidence. Three works only have survived. These are the Milindā-pañha, edited by V. Trenckner, and translated by Rhys Davids under the title Question of Milinda; the Netti Pakarasa, edited by E. Hardy for the Pali Text Society in 1902; and the Patala Upadesa. The former belongs to the north-west, the others to the centre of India, and all three may be dated vaguely in the first or second centuries A.D.

The first, a religious romance of remarkable interest, may owe its preservation to the charm of its style, the others to the accident that they were attributed by mistake to a famous apostle. In any case they are the sole survivors of what must have been a large literature.
have been a vast and varied literature. Professor Takakusu has shown the possibility of several complete books belonging to it being still extant in Chinese translations, and we may yet hope to recover original fragments in central Asia, Tibet, or Nepal.

At p. 66 of the *Gandha Vamsa*, a modern catalogue of Pali books and authors, written in Pali, there is given a list of ten authors who wrote Pali books in India, probably southern India. We may conclude that these books are still extant in Burma, where the catalogue was drawn up. Two only of these ten authors are otherwise known. The first is Dhammapāla, who wrote in Kāśipura, the modern Conjevaram in south India, in the 5th century of our era. His principal work is a series of commentaries on five of the lyrical anthologies included in the miscellaneous Nikāya. Three of these have been published by the Pali Text Society; and Professor E. Hardy has discussed in the *Zeitschrift der deutschen morgenländischen Gesellschaft* (1897), pp. 105-127, all that is known about him. Dhammapāla wrote also a commentary on the Netti mentioned above. The second is Buddhaddāta, who wrote the *Jindānākāra* in the 5th century a.d. It has been edited and translated by Professor J. Gray. It is a poem, of no great interest, on the life of the Buddha.

The whole of these Pali books composed in India have been lost there. They have been preserved for us by the unbroken succession of Pali scholars in Ceylon and Burma. These scholars (most of them members of the Buddhist Order, but many of them laymen) not only copied and recopied the Indian Pali books, but wrote a very large number themselves. We are thus beginning to know something of the history of this literature. Two departments have been subjected to critical study: the Ceylon chronicles by Professor W. Geiger in his Mahāvamsa und Dipavamsa, and the earlier grammatical works by Professor O. Franke in two articles in the *Journal of the Pali Text Society* for 1903, and in his *Geschichte und Kritik der einheimischen Pali Grammatik*. Dr Forchhammer in his *Jardine Prize Essay*, and Dr Mabel Bode in the introduction to her edition of the Sāsana-ṃīśa, have collected many details as to the Pali literature in Burma.

The results of these investigations show that in Ceylon from the 3rd century B.C. onwards there has been a continuous succession of teachers and scholars. Many of them lived in the various vihāras or residences situated throughout the island; but the main centre of intellectual effort, down to the 8th century, was the Mahāvihāra, the Great Minster, at Anurādhapura. This was, in fact, a great university. Authors refer, in the prefaces to their books, to the Great Minister as the source of their knowledge. And to it students flocked from all parts of India. The most famous of these was Buddhaghosa, from Behar in North India, who studied at the Minster in the 5th century A.D., and wrote there all his well-known works. Two volumes only of these, out of about twenty still extant in MS., have been edited for the Pali Text Society. About a century before this the Dipa-ṃīśa, or Island Chronicle, had been composed in Pali verse so indifferent that it is apparent the work was a beginning of the Pali composition. No work written in Pali in Ceylon at a date older than this has been discovered yet. It would seem that up to the 4th century of our era the Sinhalese had written exclusively in their own tongue; that is to say that for six centuries they had studied and understood Pali as a dead language without using it as a means of literary expression. In Burma, on the other hand, where Pali was probably introduced from Ceylon, no writings in Pali can be dated before the 11th century of our era. Of the history of Pali in Siam very little is known. There have been good Pali scholars there since late medieval times. A very excellent edition of the twenty-seven canonical books has been recently printed there, and there exist in our European libraries a number of Pali MSS. written in Siam.

It would be too early to attempt any estimate of the value of this secondary Pali literature. Only a few volumes, out of several hundreds known to be extant in MS., have yet been published. But the department of the chronicles, the only

1 *Journal of the Pali Text Society* (1905), pp. 72, 86.

PALIKAO

one so far at all adequately treated, has thrown so much light on many points of the history of India that we may reasonably expect results equally valuable from the publication and study of the remainder. The works on religion and philosophy especially will be of as much service for the history of ideas in these later periods as the publication of the canonical books has already been for the earlier period to which they refer. The Pali books written in Ceylon, Burma and Siam will be our best and oldest, and in many respects our only, authorities for the sociology and politics, the literature and the religion, of their respective countries.

1 *Journal of the Pali Text Society* (1905), pp. 72, 86.

**PALIKAO, CHARLES GUILLAUME MARIE APPOLLINAIRE ANTOINE COUSIN MONTAUBAN,** Comte de (1796-1878), a general and administrator, was born in Paris on the 24th of June 1796. As a cavalry officer young Montauban saw much service in Algeria, but he was still only a colonel when in 1847 he effected the capture of Abd-el-Kader. After rising to the rank of general of division and commanding the province of Constantine, he was appointed in 1858 to a command at home, and at the close of 1859 was selected to lead the French troops in the joint French and British expedition to China. His conduct of the operations did not escape criticism, but in 1862 he received from Napoleon III. the title of comte de Palikao (from the action of that name); he had already been made a senator. The allegation that he had acquired a vast fortune by the plunder of the Pekin summer palace seems to have been without foundation. In 1865 he was appointed to the command of the IV. army corps at Lyons, in the training of which he displayed exceptional energy and administrative capacity. In 1870 he was not given a command in the field, but after the opening disasters had shaken the whole of France, he was entrusted by the emperor-regent with the portfolio of war, and became president of the council (Aug. 10). He at once, with great success, reorganized the military resources of the nation. He claimed to have raised Marshal MacMahon's force at Châlons to 140,000 men, to have created three new army corps, 33 new regiments and 100,000 gards mobiles, and to have brought the defences of the capital to a state of efficiency—all this in twenty-four days. He conceived the idea of sending the army of Châlons to raise the blockade of Metz. The scheme depended on a precision and rapidity of which the army of Châlons was no longer capable, and ended with the disaster of Sedan. After the capitulation of the emperor the dictatorship was offered to Palikao, but he refused to desert the empire, and proposed to establish a council of national defence, with himself as "lieutenant-general of government." Before a decision was made, the chamber was invaded by the mob, and Palikao fled to Belgium. In 1871 he appeared before the parliamentary commission of inquiry, and in the same year established Un Ministère de la guerre de vingt-quatre jours. He died at Versailles on the 8th of January 1878.
PALIMPSEST. The custom of removing writing from the surface of the material on which it had been inscribed, and thus prepa- ring that surface for the reception of another text, has been practised from early times. The term palimpsest (from Gr. παλιμπέστ, again, and ψαλω, I scrape) is used by Catullus, apparently with reference to papyrus; by Cicero, in a passage wherein he is evidently speaking of waxen tablets; and by Plutarch, when he narrates that Plato compared Dionysius to a βιβλίον παλιμπέστου, in that his tyrant nature, being διδυσκάλειον, showed itself the imperfectly erased writing of a palimpsest MS. In this passage reference is clearly made to the washing off of writing from papyrus. The word παλιμπέστου can only in its first use have been applied to MSS. which were actually scraped or rubbed, and which were, therefore, composed of a material of sufficient strength to bear the process. In the first instance, then, it might be applied to waxen tablets; secondly, to vellum books. There are still to be seen, among the surviving waxen tablets, some which contain traces of an earlier writing under a fresh layer of wax. Papyrus could not be scraped or rubbed; the writing was washed from it with the sponge. This, however, could not be so thoroughly done as to leave a surface suitable for a subsequent use; it was therefore only used a second time for documents of an ephemeral or common nature. To apply, therefore, the title of palimpsest to a MS. of this substance was not strictly correct; the fact that it was so applied proves that the term was a common expression. Traces of earlier writing are very rarely to be detected in extant papyri. Indeed, the supply of that material must have been so abundant that it was hardly necessary to go to the trouble of preparing a papyrus, already used, for a second writing.

In the early period of palimpsests, vellum MSS. were no doubt also washed rather than scraped. The original surface of the material, at all events, was not so thoroughly defaced as was afterwards the case. In course of time, by atmospheric action or other chemical causes, the original writing would to some extent reappear; and it is thus that so many of the capital and uncial palimpsests have been successfully deciphered. In the later middle ages the surface of the vellum was scraped, renewed and the writing with it. The reading of the later examples is therefore very difficult or altogether impossible. Besides actual rasure, various recipes for effacing the writing have been found, such as to soften the surface with milk and meal, and then to rub with pumice. In consequence of such a process being used, total obliteration must almost inevitably have been the result. To intensify the traces of the original writing, when such exist, various chemical reagents have been tried with more or less success. The old method of smearing the vellum with tincture of gall restored the writing, but did irreparable damage by blackening the surface, and, as the stain grew darker in course of time, by rendering the text altogether illegible. Of modern reagents the most harmless appears to be hydro sulphate of ammonia; but this also must be used with caution.

The primary cause of the destruction of vellum MSS. by wilful obliteration was, it need hardly be said, the death of material. In the case of Greek MSS., so great was the consumption of old copies for the sake of the material, that a synodal decree of the year 691 forbade the destruction of MSS. of the Scriptures or the church fathers imperfect or injured volumes excepted. The decline of the vellum trade also on the introduction of paper caused a scarcity which was only to be made good by recourse to material already once used. Vast destruction of the broad quarto of the early centuries of our era took place in the period which followed the fall of the Roman Empire. The most valuable Latin palimpsests are accordingly found in the volumes which were remade from the 7th to the 9th centuries, a period during which the large volumes referred to must have been still fairly numerous. Late Latin palimpsests rarely yield anything of value. It has been remarked that no entire work has been found in any instance in the original text of a palimpsest, but that portions of many works have been taken to make up a single volume. These facts prove that scribes were indis- criminate in supplying themselves with material from any old volumes that had been at hand.

An enumeration of the different palimpsests of value is not here possible, use Wattenbach, O. Vat. Pal., 3rd ed., pp. 299-317; but a few may be mentioned of which facsimiles are accessible. The MS. in the Bibliothèque Nationale, Paris, known as the Codex Ephraemii, containing portions of the Old and New Testaments in Greek, attributed to the 5th century, is covered with works of Ephraem Syrus in a hand of the 11th century (ed. Tischendorf, 1843, 1845). Among the Syriac MSS. obtained from the Nitrian desert in Egypt, and now deposited in the British Museum, some important Greek texts have been recovered. A volume containing fragments of the New Testament in a hand of the 7th century, or of about 511, is written on palimpsest leaves taken from MSS. of the Titus of Homer and the Gospel of St Luke, both of the 6th century (Cat. Anc. MSS. vol. i., pl. 9), and the Elements of Euclid of the 7th or 6th century. To the same period belongs the double palimpsest, in which a text of St John Chrysostom, in Syriac, of the 9th or 10th century, covers a Latin grammatical treatise in a cursive hand of the 6th century, which in its turn has displaced the Latin version of the homilies of St Basilus Lycimnios of the 5th century (Cat. Anc. MSS. ii., pl. 12). Among Latin palimpsests also may be noticed those which have been reproduced in the Exempla of Zangemeister and Wattenbach. These are—the Ambrosian Plautus, in rustic capitals, of the 4th or 5th century, re-written with portions of the Bible (ed. Zangemeister, p. 6); the Cicero De republica of the Vatican, in uncial, of the 4th century, covered by St Augustine on the Psalms, of the 7th century (pl. 17; Pal. Soc., pl. 100); the Codex Theodosianus of Turin, of the 5th or 6th century (pl. 25); the Fasti Consulares of Verona, of A.D. 486 (pl. 29); and the Arian fragment of the Vatican, of the 5th century (pl. 31). Most of these originally belonged to the monastery of Bobbio, a fact which gives some indication of the great literary wealth of that house. By using skill and judgment, with a favour- ing light, photography may be often made a useful agent in the decipherment of obscure palimpsest texts.

PALINDROME (Gr. παλινδρομ, again, and τρόπος, a course), a verse or sentence which runs the same when read either backwards or forwards. Such is the verse—

Roma tibi subito molitus ibit amor;

or

Signa te, signa, temere me tangis et angis;

or

nika кинегмас иа мина икн.

Some have refined upon the palindrome, and composed verses each word of which is the same read backwards as forwards: for instance, that of Camden—

Odo tenet mulum, madidam mappam tenet Anna,

Anna tenet mappam madidam, mulum tenet Odo.

The following is still more complicated, as reading in four ways—upwards and downwards as well as backwards and forwards—

S A T O R  
A R E P O  
T E N E  
O P E R A  
R O T A S

PALINGENESIS (Gr. παλινγενεσία, again, γένεσις, becoming, birth), a term used in philosophy, theology, and biology. In philosophy it denotes in its broadest sense the theory (e.g. of the Pytha- goreans) that the human soul does not die with the body but is born again in new incarnations. It is thus the equivalent of metempsychosis (q.v.). The term has a narrower and more specific sense in the system of Johann Jakobbohmer, who applies it to his doctrine that the will does not die but manifests itself afresh in new individuals. He thus reproduces the primitive metem- psychosis doctrine which maintains the reincarnation of the par- ticular soul. The word “palingenesis” or rather “palingenesis” may be traced back to the Stoics, who used the term for the continual re-creation of the universe by the Demiurgus (Creator) after its absorption into himself. Similarly Philo speaks of Noah and his sons as leaders of a “renovation” or “re-birth” of the earth. Josephus uses the term of the national restoration of the Jews, Plutarch of the transmigration of souls, and Cicero of his own return from exile. In the New Testament the properly theological sense of spiritual regeneration is found, though the word itself occurs only twice; and it is used by the church fathers, e.g. for the rite of baptism or for the state of repentance. In modern biology (e.g. Haeckel and Fritz Müller)
“palingenesis” has been used for the exact reproduction of ancestral features by inheritance, as opposed to “kenogenesis” (Gr. κανόνες new), in which the inherited characteristics are modified by environment.

PALISSY, BERNARD (1510-1589), French potter (see Ceramics), is said to have been born about 1510, either at Saintes or Orléans, but both date and locality are uncertain. It has been stated, on insufficient authority, that his father was a glass-painter and that he served as his father’s apprentice. He tells us that he was apprenticed to a glass-painter and that he also acquired in his youth the elements of land-surveying. At the end of his apprenticeship he followed the general custom and became a travelling workman; acquiring fresh knowledge in many parts of France and the Low Countries, perhaps even in the Rhine Provinces of Germany and in Italy.

About 1539 it appears that he returned to his native district and, having married, took up his abode at Saintes. How he lived during the first years of his married life we have little record except when he tells us, in his autobiography, that he practised the arts of a portrait-painter, glass-painter and land-surveyor as a means of livelihood. It is known for instance that he was commissioned to survey and prepare a plan of the salt marshes in the neighbourhood of Saintes when the council of Francis I. determined to establish a salt tax in the Saintonge. It is not made clear, from his own account, whether he during his Wanderjahre or after he settled at Saintes that he was shown a white enamelled cup which caused him such surprise that he determined to spend his life—to use his own expressive phrase “like a man who gropes in the dark”—in order to discover the secrets of its manufacture. Most writers have supposed that this piece of fine white pottery was a piece of the enamelled majolica of Italy, but such a theory will hardly bear examination. In Palissy’s time pottery covered with beautiful white tin-enamel was manufactured at many centres in Italy, Spain, Germany and the South of France, and it is inconceivable that a man so travelled and so acute should not have been well acquainted with its appearance and properties. What is much more likely is that Palissy saw, among the treasures of some nobleman, a specimen of Chinese porcelain, then one of the wonders of the European world, and, knowing nothing of its nature, substance or manufacture, he set himself to work to discover the secrets for himself. At the neighbouring village of La Chapelle-des-Pots he mastered the rudiments of peasant pottery as it was practised in the 16th century. Other equipment he had none, except such indefinite information as he preserved of his travels. But his travels of the manufacture of European tin-enamelled pottery.

For nearly sixteen years Palissy laboured on in these wild endeavours, through a succession of utter failures, working with the utmost diligence and constancy but, for the most part, without a gleam of hope. The story is a most tragic one; for at times he and his family were reduced to the bitterest poverty; he burned his furniture and even, it is said, the floor boards of his house to feed the fires of his furnaces; sustaining meanwhile the reproaches of his wife, who, with her little family clamouring for food, evidently regarded these proceedings as little short of insanity. All these struggles and failures are most faithfully recorded by Palissy himself in one of the simplest and most interesting pieces of autobiography ever written. The tragedy of it all is that Palissy not only failed to discover the secret of Chinese porcelain, which we assume him to have been searching for, but that when he did succeed in making the special type of pottery that will always be associated with his name it should have been inferior in artistic merit to the contemporary productions of Spain and Italy. His first successes can only have been a superior kind of “peasant pottery,” decorated with modelled or applied reliefs coloured naturallyistically with glazes and enamels. These works had already attracted attention locally when, in 1548, the constable de Montmorency was sent into the Saintonge to suppress the revolution there. Montmorency protected the potter and found him employment in decorating with his glazed terra-cottas the château d’Écouen. The patronage of such an influential noble soon brought Palissy into fame at the French court, and although he was an avowed Protestant, he was protected by these nobles from the ordinances of all the Protestants in this district was seized. Palissy’s workshops and kilns were destroyed, but he himself was saved, and, by the interposition of the all-powerful constable, he was appointed “inventor of rustic pottery to the king and the queen-mother”; about 1563, under royal protection, he was allowed to establish a fresh pottery works in Paris in the vicinity of the royal palace of the Louvre. The site of his kilns indeed became afterwards a portion of the gardens of the Tuileries. For about twenty-five years from this date Palissy lived and worked in Paris. He appears to have been a personal favourite of Catherine de’ Medicis, and of her sons, in spite of his profession of the reformed religion.

Working for the court, his productions passed through many phases, for besides continuing his “rustic figures” he made a large number of dishes and plaques ornamented with scriptural or mythological subjects in relief, and in many cases he appears to have made reproductions of the pewter dishes of François Briot and other metal workers of the period. During this period too he gave several series of public lectures on natural history and the art of porcelain, and some of these have been published. His works were widely sold and were much admired in France, Germany and Italy, and they were much sought after in England by such as Francis I., Henry III., and Catherine de’ Medicis. He was a man of great versatility, and he is the inventor of the potter’s wheel, and the shelter of the kiln. He died in Paris on the 1st of August 1589.

Palissy’s Pottery.—The technique of the various wares he made shows their derivation from the ordinary peasant pottery of the period, though Palissy’s productions are, of course, vastly superior to anything of their kind previously made in Europe. It appears almost certain that he never used the potter’s wheel, as all his best known pieces have evidently been pressed into a mould and then finished by moulding or by the application of ornament moulded in relief. His most characteristic productions are the large plate, ewers and dishes and vases to which he applied realistic figures of reptiles, fish, shells, plants and other objects. This is, however, not the work of an artist, but...

Rustic Plate by Palissy.
manufactured after his removal to Paris, as the shells are always well-known forms from the Eocene deposits of the Paris basin. Casts from these objects were fixed on to a metal disc or base of a very high and a metal sheet on which the whole formed a mould from which Palissy could reproduce many articles of the same kind. The various parts of each piece were painted in realistic colours, or as nearly so as could be reached by the pigments Palissy was able to discover and prepare. These colours were mostly various shades of blue from indigo to ultramarine, some rather vivid greens, several tints of browns and greys, and, more rarely, yellow. A careful examination of the most authentic Palissy productions shows that they excel in the sharpness of their modelling, in a perfect neatness of manufacture and, above all, in the subdued richness of their general tone of colour. The crude greens, bright purples and yellows are only found in the works of his imitators; whilst in the marbled colours on the backs of the dishes Palissy's work is soft and well fused, in the imitations it generally is, for the ill-defined and uneven. Other pieces, such as dishes and plates, were ornamented by figure subjects treated after the same fashion, generally scriptural scenes or subjects from classical mythology, copied, in many cases, from works in sculpture by contemporary artists.

Another class of designs used by Palissy were plates, basse and the like, with geometrical patterns moulded in relief and pierced through, forming a sort of open network. Perhaps the most successful, as works of art, were those plates and ewers which Palissy moulded in exact facsimile of the rich and delicate works in pewter for which François Briot and other Swiss metal-workers were so celebrated. These are in very slight relief, executed with cameo-like finish, and are mostly of good design belonging to the school of metal-working developed by the Italian goldsmiths of the 16th century. Palissy's ceramic reproductions of these metal plates were not improved by the colours with which he picked out the designs.

Some few enamelled earthenware statuettes, full of vigour and expression, have been attributed to Palissy; but it is doubtful whether he ever worked in the round. On the whole his productions cannot be assessed as a high rank, though Palissy had always been highly valued, and in the 17th century attempts were made, both at Delft and Lambeth, to adapt his "rustic" dishes with the reliefs of animals and human figures. These imitations are very quickly painted, and are generally marked on the back in blue with initials and a date—showing them to be honest adaptations to a different medium, not attempts at forgery such as have been produced during the last fifty years. The first efforts of the Palissy revival in faience, a movement that was in great activity between 1840 and 1870, was the appearance of copies of Palissy's "Bestiâle" dishes, made with great skill and success by Avisseau of Tours, and afterwards of pieces by a number of the best artists of the period. Though both these men produced excellent works of their own, collectors have had great cause to regret the excellence of their copies, for many of the best, being unmarked, have found their way into good collections. The well-known potter, Barlow, who imitated their work, had a grace that, if anything, would have suited the original times; but he was generally marked on the back in blue with initials and a date—showing them to be honest adaptations to a different medium, not attempts at forgery such as have been produced during the last fifty years. his patron Count Trissino. In 1547 he returned to Vicenza, where he designed a very large number of fine buildings—among the chief being the Palazzo della Ragione, with two storeys of open arcades of the Tuscan and Ionic orders, and the Barbaro, Porti and Chierregati palaces. Most of these buildings look better on paper than in reality, as they are mainly built of brick, covered with stucco, now in a very dilapidated condition; but this does not affect the merit of their design, as Palladio intended them to have been executed in stone. Pope Paul III. sent for him to Rome to report upon the state of St. Peter's. In Venice, too, Palladio built many stately churches and palaces, such as S. Giorgio Maggiore, the Capuchin church, and some large palaces on the Grand Canal. His last great work was the Teatro Olimpico at Vicenza, which was finished, though not altogether after the original design, by his pupil and fellow citizen Scamozzi.

In addition to his town buildings Palladio designed many country villas in various parts of northern Italy. The villa of Capra is perhaps the finest of these, and has frequently been imitated. Palladio was a great student of classical literature, and published in 1575 an edition of Caesar's Commentaries with notes. His quarto Libri, first published at Venice in 1570, has passed into countless editions, and been translated into every European language. The original edition is a small folio, richly illustrated with well-executed full-page woodcuts of plans, elevations, and details of buildings—chiefly either ancient Roman temples or else palaces designed and built by himself. Among many others, an edition with notes was published in England by Inigo Jones, most of whose works; and especially the palace of Whitehall, of which only the banqueting room remains, owed much to Palladio's inspiration. The style adopted and partially invented by Palladio expressed a kind of revolt against the extreme licence both of composition and ornament into which the architecture of his time had fallen. He was fascinated by the stateliness and proportion of the buildings of ancient Rome, and did not reflect that reproductions of these, however great their archaeological accuracy, could not but be lifeless and unsuited to the wants of the 16th century. Palladio's carefully measured drawings of ancient buildings are now of great value, as in many cases the buildings have disappeared or have suffered in some measure. PALLADIUM (Gr. παλλάδιον), an arcaic wooden image (Φάαιρος) of Pallas Athena, preserved in the temple of Troy as a pledge of the safety of the city. It represented the goddess, standing in the stiff archaic style, holding a spear in her right hand, in her left a distaff and spindle or a shield. According to Apollodorus (iii. 12, 3) it was made by order of Athena, and was intended as an image of Pallas, the daughter of Triton, whom she had accidentally slain, Pallas and Athena being thus regarded as two distinct beings. It was said that Zeus threw it down from heaven when Ilus was founding the city of Ilium, Odysseus and Diomedes carried it off from the temple of Athena, and thus made the capture of Troy possible. According to some accounts, there was a second Palladium at Troy, which was taken to Italy by Aeones and kept in the temple of Vesta at Rome. Many cities in Greece and Italy claimed to possess the genuine Trojan Palladium. Its theft is a frequent subject in Greek art, especially of the earlier time.

PALLADIUM [symbol Pd, atomic weight 106.7 (O = 16)], in chemistry, a metallic element associated with the platinum group. It is found in platinum ores, and also in the native condition and associated with gold and silver in Brazilian gold-bearing sand. Many methods have been devised for the isolation of the metal from platinum ore. R. Bunsen (Ann., 1853, 146, p. 265), after removing most of the platinum as ammonium chloroplatinate, precipitates the residual metals of the group by iron; the resulting precipitate is then heated with ammonium chloride and evaporated with fuming nitric acid, the residue taken up in water, and the palladium precipitated as potassium palladium chloride. This is purified by dissolving it in hot water and evaporating the solution with oxalic acid, taking up the residue in potassium chloride, and filtering off any potassium platinochloride formed. The filtrate deposits potassium palladium chloride, which on heating in a current of hydrogen leaves a residue of the metal. Roeisers (Zeit. f. chemie, 1866, p. 175) precipitates both platinum and palladium as double chlorides, the resulting mixed chlorides being reduced to the metals by ignition in hydrogen, taken up in aqua regia, the solution neutralized, and the palladium precipitated by mercuric cyanide. See also T. Wilm (Ber., 1880, 13, p. 1108; 1881, 14, p. 629; 1882, 15, p. 241) on its separation as palladammic chloride, and Cox (Phil. Mag., 1843, 23, p. 16) on the separation of palladium from Brazilian gold sand. Pure palladium may be obtained by the reduction of the double chloride (NH₄)₂PdCl₄ in a current of hydrogen, or of palladium chloride with formic acid.

It is a ductile metal of silvery lustre, with a specific gravity of 11-97 (°C). It is the most easily fusible of the metals of the palladium group, the melting-point being about 1530-1550 °C. (L. Holborn and F. Hensel, Sitzb. Berl., 1900, 53, 1.) It readily distils when heated in the electronic furnaces. Its mean specific heat between 0° and 100° is 0-0582 + 0-000010t (J. Violle, Comptes rendus, 1879, 89, p. 702). Palladium finds application in the form of alloys for astronomical instruments, in dentistry, and in the construction of springs and movements of clocks. Native palladium is dimorphous. It is soluble in nitric acid, more especially if the acid contains oxides of nitrogen, and when obtained in the finely divided condition by reduction of its salts, it is to some extent soluble in hydrochloric acid. It also dissolves in boiling concentrated sulphuric acid and in hydriodic acid. It oxidizes when fused with caustic alkalis. It combines with fluoride and with chloride at a dull red heat, but not with iodine, whilst bromine has scarcely any action on the metal. It combines with sulphur directly, and according to T. Wilm (Ber., 1882, 15, p. 2225) forms the oxide PdO, when heated in a current of air.

Two series of salts are known, namely, palladous salts and palladic salts, corresponding to the two oxides PdO and PdO₂. Of these the palladous salts only are stable, the palladic salts readily passing into the palladous state. The palladous chlorides and bromides of the palladium compounds show a complete analogy with the corresponding platinum salts. All the salts of the metal when heated decompose and leave a residue of the metal; the metal may also be obtained from the oxide Pd₂O₃ by the addition of zinc, iron, cobaltic acid, phosphorus and hot alcohol. Sulphured hydrogen gives with palladous salts a precipitate of palladous sulphide which is insoluble in ammonium sulphide; mercuric chloride gives the characteristic yellowish precipitate of palladous chloride, and potassium iodide the black palladous iodide which dissolves in addition of excess of the precipitant. These two latter reactions may be used for the recognition of palladium, as may also the behaviour of the salts with ammonia, this reagent giving a brown precipitate, which turns to a red shade, and is soluble in a large excess of the precipitant to a clear solution, from which by adding hydrochloric acid a yellow precipitate of palladassium chloride, Pb(NH₃)₂Cl₄, is obtained. Palladium is permeable to hydrogen at a temperature of 130°, and the gas is absorbed and separated from other gases, the heat of occlusion being 4500 calories per gram of hydrogen. The occluded hydrogen is strongly bound to the metal, only traces of the gas being given off on standing in vacuo, but it is easily removed when heated to 100°. C. T. Graham (Phil. Mag., 1866-1868) was of the opinion that the occluded hydrogen underwent great condensation and behaved as a quasi-metal (to which he gave the name "hydrogennium"), forming an alloy with the palladium. L. H. D. van der Plas (J. chim. phys., 1874, 5, p. 279) considered that a definite compound of composition PdH₂ was formed. The more recent work of C. Hoitsma (Zeit. phys. chim., 1893, 17, p. 1) however, appears to disprove the former idea, and suggests a decomposition into a definite compound of composition PbH₂ (1874, 4, p. 324, 342). A palladium hydride was obtained by Graham by the reduction of palladium sulphate with sodium hypophosphite. It is an unstable black powder, which readily loses hydrogen at C. C. Paal and J. Gerum (Ber., 1898, 21, p. 271) have shown that when palladium black is suspended in water one volume of the metal combines with 1204 volumes of hydrogen, or in the atomic proportion Pd/H = 1/58.
KNEMER.CH.

Palladium oxide, PdO, is a black powder formed by heating sponge palladium to a dull red heat in a current of oxygen or by gentle ignition of the nitrate. It is insoluble in acids, is easily reduced, and decomposes when heated. Palladic oxide, PdO₂, is prepared by the action of ozone on palladium chloride; by the electrolytic oxidation of palladi-
ous nitrate in slightly acid solution (L. Wöhler); and by the action of caustic potash on potassium palladio-chloride, the liquid being neutralized, the yellow precipitate obtained is heated to dryness (L. Wöhler, Ann., 1806, 39, 47, p. 287). It is a dark red or brown powdered powder, which loses oxygen on heating. When boiled with water it passes into the lower oxide. It is an energetic oxidizing agent, and when freshly prepared may be dried in air, but many months old will yield a soluble oxide. When treated with a cold alcoholic solution of the monoxide, PdO₃H₂O, is obtained by hydrolyzing a faintly acid solution of the nitrate (L. Wöhler, Zeits. anorg. Chem., 1805, 46, p. 333), or by the action of a slight excess of caustic soda on the double chloride. It is insoluble in water, but when added to the solution yields palladodiammine chloride, Pd(NH₃)₂Cl₂. Palladochrome combines with hydroxylamine to form the compounds Pd(NH₃)₄Cl₂ and Pd(NH₃)₄Cl₆. The first results from the action of hydroxyl-
amine on the palladodiammine, the latter, as may be observed, may be iscarded as the free base. The other is thrown down as a yellow granular precipitate when a small quantity of dilute hydro-
chloric acid is added to the base, Pd(NH₃)₄(OH)₂. (S. Feisel and A. J. H. Poellnitz, Zeits. anorg. Chem., 1861, 55, 318). Palladchrome is known in acid solution, and is obtained when palladium is dissolved in aqua regia or when palladic oxide is dissolved in concentrated hydrochloric acid. The solution is brown in colour and gradually loses activity, as shown by the solution becoming brownish after some time. Palladi-
chrome solutions, when treated with many other metallic chlorides to form characteristic double salts, the double potassium salts having the formula K₂PdCl₄ and K₂PdCl₂. The former may be prepared by adding an excess of potassium chloride to the palladochrome solution, and the latter by boiling K₂PdCl₄ with a large excess of water. It crystallizes in pisms which are readily soluble in water but are practically insoluble in alcohol. It is decomposed by direct heating, and is no longer known on cooling. The latter observations may be explained by it being formed when chloric is passed into a warm aqueous solution of the former or by dissolving palladium in aqua regia and saturating the solution with potassium chloride. It crystallizes in scarlet octahedrons, as a complume, it is decomposed by heating. It is slightly soluble in cold water, but dissolves in warm dilute hydrochloric acid. When boiled with alcohol it is reduced to the metallic condition.

The palladium sulphide, PdS, is obtained as a hard, green coloured mass when palladochrome chloride is fused with sulphur or when the sulphide PdS is fuscd with sulphur and ammonium chloride. It loses sulphur slowly when heated and is insoluble in acids. Pal-
ladchrome sulphide, PdS₂, is obtained by precipitation of PdS by corre-
ponding salts with sulphuretted hydrogen, or by the action of dry sulphuretted hydrogen on palladochrome chloride. As prepared in the dry way it is a hard, blue coloured, insoluble mass, but it is decomposed by boiling water. It is obtained as a dark reddish-brown mass when added to cold water and is soluble in nitric acid. When heated in air it oxidizes to a basic sulphate. The disulphide, PdS₂, is a brownish-black crystalline powder which is formed when the double ammonium palladium chloride, NH₄PdCl₆, is treated with a solution of sulphuric acid in the presence of sodium. It combines with the alkali sulphides. It gradually loses sulphur on heating, and is easily soluble in aqua regia. A sulphide of composition Pd₃S₄ has been described (R. Schneider, Pogg. Ann. Chem., 1835, 105, 225).

Palladium sulphate, PdSO₄·2H₂O, is obtained by dissolving the oxide in sulphuric acid, or by the action of nitric and sulphuric acids on the metal. It forms a redish-brown, deliquescent, crystalline powder which is slowly soluble in water. It is obtained by boiling with precipitation of the base nitrate, Pd(NH₄)₂(SO₄)₂, and is used as a base nitrate, Pd(NH₄)₂(SO₄)₂, crystallizes in brownish-yellow, deliquescent prisms and is obtained by dissolving the metal in nitric acid. It is used in the preparation of the nitrate, Pd(NO₃)₂, and by introduction of the solution into a boiling mixture of nitric acid and water, it is precipitated as Pd(NO₃)₂·H₂O, a simple decomposed by boiling, with precipitation of a base nitrate, Pd(NH₄)₂(SO₄)₂·H₂O. Palladium cyanide, Pd(CN)₂, is obtained as a yellowish precipitate when palladium chloride is precipitated by mercuric cyanide. It is insoluble in water and on heating decomposes into palladium and cyanogen. It is soluble in solutions of the alkali cyanides, with formation of double cyanides of the type K₂Pd(CN)₂. On account of its insolubility and its stability it is useful for the separation of palladium from the other metals of the platinum group. The palladium salts combine with ammonia to form characteristic compounds, which may be grouped into two main divisions: (1) the palladamines (palladomamines) of type [Pd(NH₃)₂]X₂, and (2) the palladocyanides [Pd(NH₃)₄]X₂. The palladamines are obtained by adding a large excess of ammonia to the palladium salt, after which the solution is decomposed by boiling with precipitation of the mineral acid corresponding to the salt used. This method of pre-
paration serves well for the chloride, from which other salts may be obtained by double decomposition. These salts are fairly stable, and purity is obtained by precipitation as a salt of a different base. It is the preparation of the corresponding palladium salts which are mostly colourless, and are not very stable; acids convert them into the palladocyanides, and they lose two molecules of ammonia very easily. They are formed by the action of a large excess of ammonia on the corresponding palladocyanide salt in the presence of water.

Numerous determinations of the atomic weight of palladium have been made, the values obtained varying from 106.7 to 107.249 (F. Nowak, Comptes Rendus, 1909), and 106.7 to 107.249 (F. Nowak, Comptes Rendus, 1909).

PALLADIUS, RUTILUS TAURUS AEMILIANUS, a Roman author of the 4th century A.D. He wrote a poem on agriculture (De rer pastorali) in fourteen books, the material being derived from Columella and other earlier writers. The work is con-
nveniently arranged, but far inferior in every other respect to that of Columella.

There is a modern German edition by Schmitt (Leipzig, 1898).

PALLANZA, a small industrial town and summer and winter resort of the province of Novara, Piedmont, Italy, 659 ft. above sea-level. Pop. (1901), 4619 (town); 5347 (commune). It occupies a position of great natural beauty, on a promontory on the W. of Lago Maggiore, with a semicircle of mountains behind and the lake and Borromean Islands in front, 62 m. N. of Novara direct. The annual mean temperature is 55° Fahr.; January, 37°. July, 74°. There is a free botanical garden.

PALLAS, PETER SIMON (1741-1811), German naturalist and traveller, the son of Simon Pallas, surgeon in the Prussian army and professor of surgery in Berlin. He was intended for the medical profession, and studied at the universities of Berlin, Halle, Göttingen and Leiden. He early displayed a strong leaning towards natural history. In 1761 he went to England, where for a year he devoted himself to a thorough study of the collections and to a geological investigation of part of the coast; and at the age of twenty-three he was elected a foreign member of the Royal Society. He then spent some time in Holland, and the results of his investigations appeared at the Hague in 1766 in his Elcnon Zoophytos, and Miscellanea Zoologica, 1767-1768, in his Cynoglossa Zoologica (Berlin). In 1768 he accepted the invitation of Prince Caroline II. to fill the professorship of natural history in the Imperial Academy of Science, St Petersburg, and in the same year he was appointed naturalist to a scientific expedition through Russia and Siberia, the immediate object of which was the observation of the transit of Venus in 1769. In this leisurely journey Pallas went by Kasan to the Caspian, spent some time among the Kalmucks, crossed the Ural to Tobolsk, visited the Altai mountains, traced the Irtish to Kolyvan, went to Tomsk and the Yenisei, crossed Lake Baikal, and extended his journey to the frontiers of China. Few explorations have been so fruitful as this six years’ journey. The leading results were given in his Reisen durch verschiedene Provinzen des russischen Reichs (3 vols., St. Petersburg, 1771-1776), richly illustrated with coloured plates. A French translation in 1786-1793, in 8 vols., was published. (See Amer. Chem. Soc., 1903.)
PALLAVICINO, F.—PALLIUM

of this great journey may be mentioned: Sammlungen historischer Nachrichten über die mongolischen Völker (2 vols., St Petersburg, 1766-1803); Icones insectorum, proserpentium, 1775-1779; Pallis's contributions to the dictionary of languages of the Russian empire, 1786-1789; Icones insectorum, proserpentium Rossiae Siberique peculiarium, 1781-1806; Zoographia rossoasiatica (3 vols., 1831); besides many special papers in the Transactions of the academies of St Petersburg and Berlin. The empress bought Pallis's natural history collections for 20,000 roubles, 5000 more than he asked for them, and allowed him to keep them for life. He spent a considerable time in 1793-1794 in visiting the southern provinces of Russia, and was so greatly attracted by the Crimea that he determined to take up his residence there. The empress gave him a large estate at Simoperopol and 10,000 roubles to assist in equipping a house. Though disappointed with the Crimea as a place of residence, Pallis continued to live there, devoted to constant research, especially in botany, till the death of his second wife in 1810, when he removed to Berlin, where he died on the 8th of September 1811. The results of his journey in southern Russia were given in his Bemerkungen auf einer Reise durch die südlichen Staatthäuser des russischen Reichs (Leipzig, 1799-1801; English translation by Blagdon, vols. v-viii. of Modern Discoveries, 1802, and another in 2 vols., 1812). Pallis also edited and contributed to Neue nordische Beitäge zur physikal schen Erd- und Völkerbeschreibung, Naturgeschichte, und Oekonomie (1781-1796), published Illustrationen plantrum imperfecte vel nondum cognitarum (Leipzig, 1803), and contributed to Buffon's Natural History a paper on the formation of mountains.

PALLAVICINO, PERRANTE (1618-1644), Italian writer of paquinades, a member of the old Italian family of the Pallavicini, was born at Piacenza in 1618. He received a good education at Padua and elsewhere, and early in life entered the Augustinian order, residing chiefly in Venice. For a year he accompanied Ottavio Piccolomini, duke of Amalfi, in his German campaigns as field chaplain, and shortly after his return he published a number of clever but exceedingly scurrilous satires on the Roman curia and on the powerful house of the Barberini, which was so keenly resented at Rome that a price was set on his head. A Frenchman, Charles de Breche, decoyed him from Venice to the neighbourhood of Avignon, and there betrayed him. After fourteen months' imprisonment he was beheaded at Avignon on the 6th of March, 1644.

His Opere ormesse were published at Venice in 1655, but being, as may be imagined, inferior in scurrility and grossness (Pallavicino's specialities), are much less prized by the curious than the Opere selecte (Geneva, 1660), which were more of the same nature reprinted in Holland, and were translated into German in 1669.

PALLAVICINO (or PALLAVICINI), PIETRO SPORZA (1607-1667), Italian cardinal and historian, son of the Marquis Alessandro Pallavicino of Parma, was born at Rome in 1607. Having taken holy orders in 1630, and joined the Society of Jesus in 1638, he successively taught philosophy and theology in the Collegium Romanum; as professor of theology he was a member of the congregation appointed by Innocent X. to investigate the Jansenist heresy. In 1650 he was made a cardinal by Alexander VII. He died at Rome on the 5th of June 1667. Pallavicino is chiefly known by his history of the council of Trent, written in Italian, and published at Rome in two folio volumes in 1656-1657 (2nd ed., considerably modified, in 1666). In this he continued the task begun by Terenzo Alciati, who had been commissioned by Urban VIII. to correct and supersede the very damaging work of Sarpi on the same subject. Alciati and Pallavicino had access to many important sources from the use of which Sarpi had been precluded; the contending parties, however, are far from agreed as to the completeness of the refutation. The work was translated into Latin by a Jesuit named Giattinus (Antwerp, 1670-1673). There is a good edition of the original by Zaccharia (6 vols., Faenza, 1792-1799). It was translated into German by Klitsche in 1835-1837. He also wrote a life of Alexander VII. and a tragedy (Ermenegildo, 1644), &c.

His collected Opere were published in Rome in 1844-1848.

PALLIUM or FAL (derived, so far as the name is concerned, from the Roman paulum or palla, a woollen cloak), an ecclesiastical vestment in the Roman Catholic Church, originally peculiar to the pope, but for many centuries past bestowed by him on all metropolitan, primates, and archbishops as a symbol of the jurisdiction delegated to them by the Holy See. The pallium, in its present form, is a narrow band, three fingers broad, of white lamb's wool, with a loop in the centre resting on the shoulders over the chasuble, and two dependent lappets, before and behind; so that when worn from front or back the ornament resembles the letter Y. It is decorated with six purple crosses, one on each tail and four on the loop, is doubled on the left shoulder, and is garnished, back and front, with three jewelled gold pins. The two latter characteristics seem to be survivals of the time when the Roman pallium, like the Greek ψηφίσμα, was a simple scarlet doubled and pinned on the left shoulder.

The origin of the pallium as an ecclesiastical vestment is lost in antiquity. The theory that explains it in connexion with the figure of the Good Shepherd carrying the lamb on his shoulders, so common in early Christian art, is obviously an explanation posteriori. The ceremonial connected with the preparation of the pallium and its bestowal upon the pope at his coronation, however, suggests some such symbolism. The lambs whose wool is destined for the making of the palla are solemnly presented at the altar by the nuns of the convent of St Agnes at Rome at mass on St Agnes' day, during the singing of the Agnus Dei. They are received by the canons of the Lateran church and handed over to them by the apostolic subdeacons, by whom they are put out to pasture till the time of shearing. The palla fashioned of their wool by the nuns is carried by the subdeacons to St Peter's, where they are placed by the canons on the bodies of St Peter and St Paul, under the high altar, for a night, then committed to the subdeacons for safe custody. A pallium thus consecrated is placed by the archdeacon over the shoulders of the pope at his coronation, with the words "Receive the pallium," i.e. the plenitude of the pontifical office, "to the glory of God, and of the most glorious Virgin His Mother, and of the blessed apostles St Peter and St Paul, and of the Holy Roman Church."
PALL-MALL

The elaborate ceremonial might suggest an effort to symbolize the command "Feed My lambs!" given to St Peter and its transference to Peter's successors. Some idea underlies the developed ceremonial; but the pallium itself was in its origin no more than an ensign of the episcopal dignity, as it remains in the East, where—under the name of ὄμορφον (όμος, shoulder, φέρειν, to carry)—it is worn by all bishops. Moreover, whatever symbolism may be evolved from the lambs' wool is vitiated, so far as origins are concerned, by the fact that the papal pallia were at one time made of white linen (see Johannes Diaconus, Vita S. Gregorii M. lib. IV. cap. 8, pallium ejus byso cavidente contextum).  

The right to wear the pallium seems, in the first instance, to have been conceded by the popes merely as a mark of honour. The first recorded example of the bestowal of the pallium by the popes is the grant of Pope Symmachus in 513 to Caesarius of Arles, as papal vicar. By the time of Gregory I. it was given not only to vicars but as a mark of honour to distinguish bishops, and it is still conferred on the bishops of Autun, Bamberg, Döl, Lucca, Ostia, Pavia and Verona. St Boniface caused a reforming synod, between 840 and 850, to decree that in future all metropolitans must seek their pallium at Rome (see Boniface's letter to Cuthbert, 78, Monumenta Germaniae, epochalae, III.); and though this rule was not universally followed even until the 13th century, it is now uncanonical for an archbishop to exercise the functions proper to his office until the pallium has been received. Every archbishop must apply for it, personally or by deputy, within three months after his consecration and it is buried with him at his death (see Archbishop).  The pallium is never granted until after payment of considerable dues. This payment, originally supposed to be voluntary, became one of the great abuses of the papacy, especially during the period of the Renaissance, and it was the large amount (raised largely by indulgences) which was paid by Albert, archbishop of Magdeburg, to the papacy that roused Luther to protest. Though the pallium is thus a vestment distinctive of bishops having metropolitan jurisdiction, it may only be worn by them within their jurisdiction, and then only on certain solemn occasions.  The pope alone has the right to wear everywhere and at all times a vestment which is held to symbolize the plenitude of ecclesiastical power.  

See P. Hinschius, Kirchenrecht, II. 23 sqq.; Greiser, "Das römische Pallium und die ältesten liturgischen Schärfen" (in Festschrift zum elftundigkeitlichen Jubiläum des Capitoliu Rom, Freiburg, 1897); Du Cange, Glossarium s. v. "Pallium"; Joseph Braun, Die liturgische Gewandung im Occident und Orient (Freiburg-i-B., 1907).  

PALL-MALL, an obsolete English game of French origin, called in France paille-maillé (from paille, ball, and mallet, mallet). Sir Robert Dallington, in his Method for Travel (1598), says, "Among all the exercises of France, I prefer none before the Paille-Maillé." James I., in his Basilikon doron, recommended it as a proper game for Prince Henry, and it was actually introduced into England in the reign of Charles I., or perhaps a few years earlier. Thomas Blount's Glossographia (ed. 1670) describes it as follows: "Pale Maile, a game wherein a round bowl is with a mallet struck through a high arch of iron (standing at either end of an alley), which he that can do at the fewest blows, or at the number agreed on, wins. This game was herefor used in the long-alley near St James's, and vulgarly called Poll-Mell." The pronunciation here described as "vulgar" afterwards became classic. A mallet and balls used in the game were found in 1825 and are now in the British Museum. The mallet resembles that used in croquet, but its head is curved and its ends slopes towards the shaft. The balls used in both are small and about the size of a common snuff bottle. Pepys describes the alley as of hard sand "dressed with powdered cockle-shells." The length of the alley varied, that at St James's being about 800 yds. Some alleys had side walls.  

1 Father Joseph Braun, S.J., holds that the pallium, unlike other vestments, had a liturgical origin, and that it was akin to the scarves of office worn by priests and priestesses in pagan rites. See Die pontifikalen Gewänder des Abendlandes, p. 174 (Freiburg-i-B. 1898).  

PALLONE (Italian for "large ball," from palla, ball), the national ball game of Italy. It is descended, as are all other court games, such as tennis and pelota, from the thank ball games played by the Romans, in one of which a large inflated ball, called prolis, was used. The other, probably the immediate ancestor of pallone, was played with a smaller ball, the pilota. Pallone was played in Tuscany as early as the 14th century, and is still very popular in northern and central Italy. It is played in a court (sferisterio), usually 100 yds. long and 17 yds. wide. A white line crosses the middle of the court, which is bounded on one side by a high wall, the spectators sitting round the other three sides, usually protected by wire screens. One end of the court is called the battuto and the other the ribattuto. At the end of the battuto is placed a spring-board, upon which stands the player who receives the service. The implements of the game are the pallone (ball) and the bracciale (bat). The pallone is an inflated ball covered with leather, about 4½ in. in diameter. The bracciale is an oak gauntlet, tubular in shape, and covered with long spike-like protruberances. It weighs between five and six pounds and is provided with a grip for the hand. The game is played by two sides—blues and reds—of three men each, the battitore (batter), spalla (back) and terzino (third). At the beginning of a game the battitore stands on the spring-board and receives the ball thrown to him on the bound by a seventh player, the mandarino, who does duty for both sides. The batter may ignore the ball until it comes to him to his liking, when he runs down the spring-board and strikes it with his bracciale over the centre line towards his opponents. The game then proceeds until a player fails to return the ball correctly, or hits it out of bounds, or it touches his person. This counts a point for the adversary. Four points make a game, counting 15, 30, 40 and 50.  

See Il Giuoco del pallone, by G. Franceschini (Milan, 1903).  

PALM, JOHANN PHILIPP (1768–1806), German bookseller, a victim of Napoleonic tyranny in Germany, was born at Schorndorf, in Württemberg, on the 17th of November 1768. Having been apprenticed to his uncle, the publisher Johann Jakob Palm (1750–1826), in Erlangen, he married the daughter of the bookseller Stein in Nuremberg, and in course of time became proprietor of his father-in-law's business. In the spring of 1806 the firm of Stein sent to the bookselling establishment of Stage in Augsburg a pamphlet (presumably written by Philipp Christian Yelin in Ansbach) entitled Deutschland in seiner tiefen Bedrängung ("Germany in her deep humiliation"), which strongly attacked Napoleon and the behavior of the French troops in Bavaria. Napoleon, on being apprised of the violent attack made upon his régime and failing to discover the actual author, had Palm arrested and handed over to a military commission at Braunau on the Bavarian-Austrian frontier, with peremptory instructions to try and execute the prisoner within twenty-four hours. Palm was denied the right of defence, and after a mock trial on the 25th of August 1806 he was shot on the following day. A life-size bronze statue was erected to his memory in Braunau in 1866, and on the centenary of his death numerous patriotic meetings were held in Bavaria.  

See F. Schultheis, Johann Philipp Palm (Nuremberg, 1869); and J. Hackl, Der nürnberger Buchhändler Johann Philipp Palm (Nuremberg, 1906).  

PALM (Lat. palma, Gr. παλάμι), originally the flat of the hand, in which sense it is still used; from this sense the word was transferred as a name of the trees described below. The emblematic use of the word (= prize, honour) represents a further transference from the employment of the palm-leaves as symbols of victory. The Palms (Palmaceae) have been termed the princes of the vegetable kingdom. Neither the anatomy of their stems nor the composition of their flowers, however, entitles them to any such high position in the vegetable hierarchy. Their stems are not more complicated in structure than those of the common butcher's broom (Ruscus); their flowers are for the most part as simple as those of a rush (Juncus). The order Palmaceae

639
is characterized among monocotyledonous plants by the presence of an unbranched stem bearing a tuft of leaves at the extremity only, or with the leaves scattered; these leaves, often gigantic in size, being usually firm in texture and branching in a pinnate or palmate fashion. The flowers are borne on simple or branching spikes, very generally protected by a spathe or spathes, and each consists typically of a perianth of six greenish, somewhat inconspicuous segments in two rows, with six stamens, or pistil of 1–3 carpels, each with a single ovule and a succulent or dry fruit, never dehiscent (fig. 1, A and B). The seed consists almost exclusively of endosperm or albumen in a cavity in which is lodged the relatively very minute embryo (fig. 1, C). These are the general characteristics by which this very well-defined order may be discriminated, but, in a group containing considerably more than a thousand species, deviations from the general plan of structure occur with some frequency. As the characteristic appearances of palms depend to a large extent upon these modifications, some of the more important among them may briefly be noticed.

Taking the stem first, we may mention that it is in very many palms relatively tall, erect, unbranched, regularly cylindrical, or dilated below so as to form an elongated cone, either smooth, or covered with the projecting remnants of the former leaves, or marked with circular scars indicating the position of those leaves which have now fallen away. It varies in diameter from the thickness of a reed (as in Chamaerops) to a sturdy pillar-like structure as seen in the date-palm, Palmyra palm (fig. 7) or Talipot. In other cases the very slender stem is prostrate, or

A, male flower. B, female-flower. C, Upper portion of Coco-nut seed showing e, embryo, embedded in d, endosperm.

In other cases it is so graceful in form as to be almost indistinguishable from a palm, and as in that case will either strike a cable-like growth, or nearly upright, or project as a tuft of leaves, or even curl itself around a tree, or the like, and so form a network of stems, to which it owes its use in the tropics, as a substitute for wood, as well as for other purposes. This is the case with the Areca palm, so much used in the East, and the Areca cactus, or Rattan, which is widely distributed in the Malay archipelago, and with the Rattan palms of the Philippine Islands, in which cases the stem is so soft as to be useless as timber.

The vegetable ivory (Phytelephas) of equatorial America has a very thick solid stem bearing a tall cluster of leaves which appears to rise from the ground. In many species the trunk is covered with a dense network of stiff fibres, often compacted together at the free ends into spines. This fibrous material, which is so valuable for cordage, consists of the fibrous tissue of the leafstalk, which in these cases persists after the decay of the softer portions. It is very characteristic of some palms to produce from the base of the stem a series of adventitious roots which gradually thrust themselves into the soil and serve to steady the tree and prevent its overthrow by the wind. The underground stem of some species, e.g. of Calamus, is a rhizome, or root-stock, lengthening in a more or less horizontal manner by the development of the terminal bud, and sending up lateral branches like suckers from the root-stock, which form dense thickets of cane-like stems. The branching of the stem above ground is unusual, except in the case of the Doum palm of Egypt (Hyphaene), where the stem forks, often repeatedly; this is due to the development of a branch to an equal strength with the main stem. In other
cases branching, when present, is probably the result of some injury to the terminal bud at the top of the stem, in consequence of which buds sprout out from below the apex.

The internal structure of the stem does not differ fundamentally from that of a typical monocotyledonous stem, the taller, harder trunks owing their hardness not only to the fibrous or woody skeleton but also to the fact that, as growth goes on, the originally soft cellular ground tissue through which the fibres run becomes hardened by the deposit of woody matter within the cells, so that ultimately the cellular portions become as hard as the woody fibrous tissue.

The leaves of palms are either arranged in more or less distant intervals along the stem, as in the canes (Calamus, Daemonorops, fig. 2, &c.), or are approximated in tufts at the end of the stem, thus forming those noble crowns of foliage (figs. 5, 6, 7) which are so closely associated with the general idea of a palm. In the young condition, while still unfolded, these leaves, with the succulent end of the stem from which they arise, form "the cabbage," which in some species is highly esteemed as an article of food.

The adult leaf very generally presents a sheathing base tapering upwards into the stalk or petiole, and this again bearing the lamina or blade. The sheath and the petiole very often bear stout spines, as in the rattan palms (see fig. 2); and when, in course of time, the upper parts of the leaf decay and fall off, the base of the leaf-stalk and sheath often remain, either entirely or in their fibrous portions only, which latter constitute the investment to the stem already mentioned. In size the leaves vary within very wide limits, some being only a few inches in extent, while those of the noble Caryota may be measured in tens of feet. In form the leaves of palms are very rarely simple, usually they are more or less divided, sometimes, as in Caryota, extremely so. In species of Geonoma, Verschaffeltia and some others, the leaf splits into two divisions at the apex and not elsewhere; but more usually the leaves branch regularly in a palmate fashion as in the fan-palms Latania, Borassus (fig. 7), Chamaerops, Sebel, &c., or in a pinnate fashion as in the feather-palms, Areca (fig. 3), Kentia, Calamus, Daemonorops (fig. 2), &c. The form of the segments is generally more or less linear, but a very distinct appearance is given by the broad wedge-shaped leaflets of such palms as Caryota, Martensia or Mauritia. These forms run one into another by transitional gradations; and even in the same palm the form of the leaf is often very different at different stages of its growth, so that it is a difficult matter to name correctly seedling or juvenile palms in the condition in which we generally meet with them in the nurseries, or even to foresee what the future development of the plant is likely to be. Like the other parts of the plant, the leaves are sometimes investied with hairs or spines; and, in some instances, as in the magnificent Ceratoxylon andicola, the under surface is of a glaucous white or bluish colour, from a coating of wax.

The inflorescence of palms consists generally of a fleshy spike, either simple or much branched, studded with numerous, sometimes extremely numerous, flowers, and enveloped by one or more sheathing bracts called "spathes" (fig. 5). These parts may be small, or they may attain relatively enormous dimensions, hanging down from amid the crown of foliage like huge tresses, and adding greatly to the noble effect of the leaves. In some cases, as in the palmetto palm, the tree only flowers once; it grows for many years until it has become a large tree then develops a huge inflorescence, and after the fruit has ripened, dies.

The individual flowers are usually small (figs. 3, 6), greenish and insignificant; their general structure has been mentioned already. Modifications from the typical structure arise from difference of texture, and specially from suppression of parts, in consequence of which the flowers are very generally unisexual (figs. 1, 3, 6), though the flowers of the two sexes are generally produced on the same tree (monoeocious), not indeed always in the same season, for a tree in

Fig. 5.—Arecocia siderocarpa, much reduced.

1. Spathe enveloping the fruits. 3. The same cut lengthwise, shown on a larger scale in 1. m. Fibrous mesocarp; en, hard endocarp; s, seed.

one year may produce all male flowers and in the next all female flowers. Sometimes the flowers are modified by an increase in the number of parts; thus the usually six stamens may be represented by 12 to 24 or even by hundreds. The carpels are usually three in number, and more or less combined; but they may be free, and their number may be reduced to two or even one. In any case each carpel contains but a single ovule.

Owing to the sexual arrangements before mentioned, the pollen has to be transported by the agency of the wind or of insects to the female flowers. This is facilitated sometimes by the elastic movements of the stamens and anthers, which liberate the pollen so freely at certain times that travellers speak of the date-palms of Egypt (Phoenix dactylifera) being at daybreak hidden in a mist of pollen grains. In other cases fertilization is effected by the agency of an insect, which removes the male flowers and scatters the pollen over the fruit-bearing trees. This practice has been followed in the case of the date from time immemorial; and it afforded one of the earliest and most irrefragable proofs by means of which the sexuality of plants was finally established. In the course of ripening of the fruit two of the carpels with their ovules may become absorbed, as in the coco-nut, the fruit of which contains only one seed though the three carpels are indicated by the three longitudinal sutures and by the presence of three germ-pores on the hard endocarp.

The fruit is various in form, size and character; sometimes, as in the common date (fig. 4) it is a berry with a fleshy rind enclosing a hard stony kernel, the true seed; the fruit of Areca (fig. 3) is similar; sometimes it is a kind of drupe as in Arecocia (fig. 5), or the coco-nut, Cocos nucifera, where the fibrous central portion investing the hard shell corresponds to the fleshy portion of a plum or cherry, while the shell or nut corresponds to the stone of stone-fruits, the seed being the kernel. In Borassus the three seeds are each enclosed in a separate chamber formed by the stony endocarp (fig. 7). Sometimes, as in the species of Metroxylon (fig. 6), Raphia, Daemonorops (fig. 2), &c., the fruit is covered with hard, pointed, reflexed shining scales, which give it a very remarkable appearance.

The seeds show a corresponding variety in size and shape, but
always consist of a mass of endosperm, in which is embedded a relatively very minute embryo (figs. 1, 3, 6). The hard stone of the date is the endosperm, the white oily flesh of the coco-nut is the same substance in a softer condition; the so-called "vegetable ivory" is derived from the endosperm of Phytelephas. In some genera the inner seed coat becomes thickened along the course of the vascular bundles and growing into the endosperm produces the characteristic appearance in section known as ruminate—this is well shown in the Areca nut (fig. 3).

The order contains 132 genera with about 1100 species mainly tropical, but with some representatives in warm temperate regions. Chamaerops humilis is a native of the Mediterranean region, and the date-palm yields fruit in southern Europe as far north as 38° N. latitude. In eastern Asia the Palms, like other tropical families, extend along the coast reaching Korea and the south of Japan. In America a few small genera occur in the southern United States and California; and in South America the southern limit is reached in the Chilean genus Jubaea (the Chile coco-nut) at 37° S. latitude. The great centres of distribution are tropical America and tropical Asia; tropical Africa contains only 11 genera, though some of the species, like the Doum palm (Hyphaene thebaica) and the Deleb or Palmrya palm (Borassus flabellifer) have a wide distribution. With three exceptions—Olea and New World forms are distinct—the coco-nut (Cocos nucifera) is widely distributed on the coasts of tropical Africa, in India and the South Seas, the other species of the genus are confined to the western hemisphere. The oil palm (Elaeis guineensis) is a native of west tropical Africa, the other species of the genus is tropical American. Raphia has also species in both tropical Africa and tropical America. The 132 genera of the order are ranked under seven tribes, distinguished by the nature of the foliage, the sexual conditions of the flower, the character of the seed, the position of the raphé, &c. Other characters serving to distinguish the minor groups are afforded by the habit, the position of the spathes, the "aestivation" of the flower, the nature of the stigma, the ovary, fruit, &c.

It is impossible to overestimate the utility of palms. They furnish food, shelter, clothing, timber, fuel, building materials, sticks, fibre, paper, starch, sugar, oil, wax, wine, tannin, dyeing materials, resin and a host of minor products, which render them most valuable to the natives and to tropical agriculturists. The Coco-nut palm, Cocos nucifera, and the Date palm, Phoenix dactylifera, have been treated under separate headings. Sugar and liquids capable of becoming fermented are produced by Caryota urens,

PALMA, J.

Cocos nucifera. Borassus flabellifer, Rhapis vinifera, Arenga saccharifera, Phoenix silvestris, Mauritia vinifera, &c. Starch is procured in abundance from the stem of the Sago palm, Metroxylon (fig. 6) and others. The fleshy mesocarp of the fruit of Elaeis guineensis of western tropical Africa yields, when crushed and boiled, "palm oil." Coco-nut oil is extracted from the oily endosperm of the coco-nut. Wax is exuded from the stem of Ceroxylon andicola and Copernicia cerifera. A variety of "dragon's blood," a resin, is procured from Daemonorops Draco and other species. Edible fruits are yielded by the date, the staple food of some districts of northern Africa. The coco-nut is a source of wealth to its possessors; and many of the species, e.g. Areca sapida (Cabbage-palm and others), are valued for their "cabbage"; but, as this is the terminal bud whose removal causes the destruction of the tree, this is a wasteful article of diet unless care be taken by judicious planting to avert the annihilation of the supplies. The famous "coco de mer," or double coco-nut, whose floating nuts are the objects of so many legends and superstitions, is known to science as Lobocereus sechellarum. The tree is peculiar to the Seychelles, where it is used for many useful purposes. Its fruit is like a huge plum, containing a stone or nut like two coco-nuts (in their husks) united together. These illustrations must suffice to indicate the numerous economic uses of palms.

The only species that can be cultivated in the open air in England, and then only under exceptionally favourable circumstances, are the European Fan palm, Chamaerops humilis, the Chusan palm, Trachycarpus Fortunei, &c., and the Chilian Jubaea spectabilis. The date palm is commonly planted along the Mediterranean coast. There are several low growing palms, such as Rhapis flabelliformis, Chamaerops humilis, &c., which are suited for ordinary green-house culture, and many of which, from the thick texture of their leaves, are enabled to resist the dry and often gas-laden atmosphere of living rooms.

PALMA, JACOPO (c. 1480–1528). Italian painter of the Venetian school, was born at Serina near Bergamo, towards 1480, and died at the age of forty-eight in July 1528. He is currently named Palma Vecchio (Old Palma) to distinguish him from Palma Giovane, his grand-nephew, a much inferior painter. His grandfather's name was Negretto. He is reputed to have been a companion and competitor of Lorenzo Lotto, and to some extent a pupil of Titian, after arriving in Venice early in the
16th century; he may also have been the master of Bonifazio. His earlier works betray the influence of the Bellini; but mooring his style from the study of Giorgione and Titian, Palma took high rank among those painters of the distinctively Venetian type who remain a little below the leading masters. For richness of colour he is hardly to be surpassed; but neither in invention nor vigorous draughtsmanship does he often attain a peculiar excellence. A face frequently seen in his pictures is that of his (so-called) daughter Violante, of whom Titian was said to be enamoured. Two works by Palma are more particularly celebrated. The first is a composition of six paintings in the Venetian church of S. Maria Formosa, with St Barbara in the centre, under the dead Christ, and to right and left SS. Dominick, Sebastian, John Baptist and Anthony. The second work is in the Dresden Gallery, representing three sisters seated in the open air; it is frequently named "The Three Graces." A third fine work, discovered in Venice in 1900, is a portrait supposed to represent Violante. Other leading examples are: the “Last Supper,” in S. Maria Mater Domini; a “Madonna,” in the church of S. Stefano in Vicenza; the “Epiphany,” in the Brera of Milan; the “Holy Family, with a young shepherd adoring” in the Louvre; “St Stephen and other Saints,” at Christ and the Widow of Nain,” and the “Assumption of the Virgin,” in the Academy of Venice; and “Christ at Emmaus,” in the Patti Gallery. The beautiful portrait of the National Gallery, London, with a background of foliage, originally described as “Ariosto,” and as by Titian, and now ascribed to that master, was for some years assumed to be an unknown poem by Palma Vecchio. It is certainly much more like the work of Titian than of Palma. In 1907 the Staedel Institute in Frankfurt acquired an important work by Palma Vecchio, identified by its director as an illustration of Ovid’s second Metamorphosis, and named “Jupiter and Calisto.” Palma’s grand-nephew, Palma Giovane, was also named Jacopo (1544 to about 1626). His works belong to the decline of Venetian art. (W. M. R.)

PALMA, or PALMA DE MALLORCA, the capital of the Spanish province of the Balearic Islands, the residence of the cathedral general, an episcopal see, and a flourishing seaport, situated 135 m. S.S.E. of Barcelona, on the south-west coast of Majorca, at the head of the fine Bay of Palma, which stretches inland for about 10 m. between Capes Cala Figuera and Regana. Pop. (1900), 63,037, including a colony of Jews converted to Christianity (Chuetas). Palma is the meeting place of all the highways in the island, and the terminus of the railway to Inca, Manacor, and Alcudia. The ramps, which enclose the city on all sides except towards the port (where they were demolished in 1872), have a circuit of a little more than 4 m. Though begun in 1562, they were not finished till 1836. Palma underwent considerable change in the 19th century, and the fine old-world Moorish character of the place suffered accordingly. The more conspicuous buildings are the cathedral, the exchange, the royal palace, now occupied by the captain-general, and the law courts, the episcopal palace, a handsome late Renaissance building (1016), the general hospital (1456), the town-house (end of the 16th century), the picture gallery, and the Caixa de la Vida. The Castell de Bellver, the seat of the Counts of Raimond Lull, a native of Palma, the cathedral was erected and dedicated to the Virgin by King James I. of Aragon as he sailed to the conquest of Majorca; but, though founded in 1230, it was not finished till 1601. The older and more interesting portions are the royal chapel (1322), with the marble sarcophagus of James II. (d. 1311) which was erected here in 1770; and the south front with the elaborately-sculptured doorway known as del mirador (1389). The exchange (lonja), a Gothic building begun in 1426, excited the admiration of the emperor Charles V. Palma has a seminary founded in 1705, a collection of archives dating from the 14th century, a school and museum of fine arts, a nautical school and an institute founded in 1836 to replace the old university (1593). The harbour, formed by a mole constructed to a length of 387 yds. in the 14th century and afterwards extended to more than 650 yds., has been greatly improved since 1875 by dredging and a further addition to the mole of 136 yds. Previously it was not accessible to vessels drawing more than 18 ft. Palma has frequent and regular communication by steamer with Barcelona, Valencia and Alicante. Puertop, about 2 m. south-west of the city, was once a good harbour, but is now fit only for small craft. Palma has a thriving trade in grain, wine, oil, almonds, fruit, vegetables, silk, foodstuffs and livestock. There are manufactures of alcohol, liqueurs, chocolate, starch, sugar, preserves, flour, soap, leather, earthenware, glass, matches, paper, linen, woollen goods and rugs.

Palma probably owes, if not its existence, at least its name (symbolized on the Roman coins by a palm branch), to Metellus Balearicus, who in 123 B.C. settled three thousand Roman and Spanish colonists on the island. The bishopric dates from the 10th century. About 1 m. south-west of the city is the castle of Bellver or Belbex, the ancient residence of the kings of Majorca. Miramar, the beautiful country seat of the archduke Ludwig Salvador of Austria, is 12 m. north of Palma.

PALMA, or SAN MIGUEL DE LA PALMA, a Spanish island in the Atlantic Ocean, forming part of the Canary Islands (q.v.). Population, 1905, 41,904; area 280 sq. m. Palma is 26 m. long with an extreme breadth of 16 m. It lies 57 m. W.N.W. of Tenerife. It is traversed from north to south by a chain of mountains, the highest of which is 7900 ft. above sea-level. At the broadest part is a crater 9 m. in diameter, known as the Caldera (i.e. cauldron). The bottom of the crater has an elevation of 2300 ft., and it is overhung by peaks that rise more than 9000 ft. above it. Palma contains several mineral springs, but there is great want of fresh water. The only stream which is never dried up is that which issues from the Caldera. In 1677 an eruption, preceded by an earthquake, took place from a volcano at the southern extremity of the island, and much damage was done. Santa Cruz de la Palma (pop. 7024) on the eastern coast is the principal town. The anchorage is good.

PALM BEACH, a winter resort on the east coast of Florida, U.S.A., in Palm Beach county, about 264 m. S. of St Augustine; served by the Florida East Coast railway. It is situated on a peninsula (about 30 m. long and 1 m. wide) separated from the mainland by Lake Worth, an arm of the Atlantic Ocean, and derives its name from the groves of coco-nut palms which fringe the lake. The coco-nut was introduced here by chance, through the wrecking of a vessel, in January 1879, of a coco-nut-laden Spanish vessel. The Gulf Stream is within about 1 m. of the shore, and the climate is mild and equable, the winter temperature normally ranging between 70° and 75° F. On the Atlantic is the Breakers, a large hotel, and facing Lake Worth is the Royal Poinciana, the largest hotel in the southern states. Palm Beach has few permanent residents and is not incorporated. On the mainland just across the lake is the city of West Palm Beach (pop. in 1905, 1280; 1910, 1743), a pleasure resort and the county-seat of Palm Beach county (created in 1900).

PALM-CIVET, or PARADOXURUS, the name of the members of the civet-like genus Paradoxurus, represented by several species mainly from south-east Asia. (See CARNIVORA.) Palm-civets are about the size of the domestic cat, or rather larger, and chiefly arboreal in habits, dark uniform in colour, spotted or striped fur. The common Indian palm-civet (P. niger) ranges throughout India, wherever there are trees, frequently taking up its abodes in roof-thatch. Its diet consists of small mammals and reptiles, birds and their eggs, fruit and vegetables. From four to six young are brought forth at a litter, and are easily tamed. Other species are the Ceylonese P. aureus, the brown P. jerdoni, the Himalayan P. grisii and the Malayan P. Herma- phroditus. The small-toothed palm-civets, from the Malay Archipelago, Sumatra and Java, have been separated from the typical group to form the genus Arctogale. In Africa the group is represented by two species of Nandinia, which show several primitive characters.

PALMELLA, a town of Portugal, in the district of Lisbon (formerly included in the province of Estremadura); at the north-eastern extremity of the Serra da Arrabida, and on the Lisbon-Setubal railway. Pop. (1900), inclusive of the neighbouring
village of Marateca, 11,478. Palmella is an ancient and picturesque town, still surrounded by massive but ruined walls and dominated by a medieval castle. In Viticulture, market gardening and fruit farming are important local industries. Palmella was taken from the Moors in 1147 by Alphonso I. (Alfonso Henríquez), and entrusted in 1160 to the knights of Santiago. The title “duke of Palmella” dates from 1354, when it was conferred on the statesman Pedro de Sousa-Holstein, count of Palmella (1781–1850).

PALMER, SIR CHARLES MARK, Bart. (1822–1907). English shipbuilder, was born at South Shields on the 3rd of November 1822. His father, originally the captain of a whaler, removed in 1828 to Newcastle-on-Tyne, where he conducted a ship-owning and ship-breaking business. Charles Palmer at the age of five entered a shipping business in that town, whence, after six months, he went to Marseilles, where his father had procured him a post in a large commercial house, at the same time entrusting him with the local agency of his own business. After two years' experience at Marseilles he entered his father's business at Newcastle, and in 1842 he became a partner. His business capacity attracted the attention of a leading local colliery, and he was appointed manager of the Marley Hill colliery in which he became a partner in 1846. Subsequently he was made one of the managers of the associated collieries north and south of the Tyne owned by Lord Ravensworth, Lord Wharncliffe, the marquess of Bute, and Lord Strathmore, and in due course he gradually purchased these properties out of the profits of the Marley Hill colliery. Simultaneously he greatly developed the then recently-established coke trade, obtaining the coke contracts for several of the large English and continental railways. About 1850 the question of coal-transport to the London market became a serious question for north country colliery proprietors. Palmer therefore built, largely according to his own plans, the “John Bowes,” the first iron screw-roller, and several other steam-collies, in a yard established by him at Jarrow, then a small Tyneside village. He then purchased iron-mines in Yorkshire, and erected along the Tyne at Jarrow large shipbuilding yards, blast-furnaces, steel-works, rolling-mills and engine works, fitted on the most elaborate scale. The firm produced war-ships as well as merchant vessels, and their system of rolling armour plates, introduced in 1856, was generally adopted by other builders. In 1865 he turned the business into Palmer's Shipbuilding and Iron Company, Limited. In 1886 his services in connexion with the settlement of the costly dispute between British ship-owners and the Suez Canal Company (of which he was then a director) were rewarded with a baronetcy. He died in London on the 4th of June 1907.

PALMER, EDWARD HENRY (1840–1884), English orientalist, the son of a private schoolmaster, was born at Cambridge, on the 7th of August 1840. He was educated at the Perse School, and as a schoolboy showed the characteristic bent of his mind by picking up the Romany tongue and a great familiarity with the life of the gypsies. From school he was sent to London as a clerk in the city. Palmer disliked this life, and varied it by learning French and Italian, mainly by frequenting the social circles of the Theatre Royal, Drury Lane. When he was 19, in 1859, he returned to Cambridge, apparently dying of consumption. He had an almost miraculous recovery, and in 1860, when he was thinking of a new start in life, fell ill with Sayyid Abdullah, teacher of Hindustani at Cambridge, under whose influence he began his Oriental studies. He matriculated at St John's College in November 1861, and in 1867 was elected a fellow on account of his attainments as an orientalist, especially in Persian and Hindustani. During his residence at St John's he catalogued the Persian, Arabic and Turkish manuscripts in the university library, and in the libraries of King's and Trinity. In 1867 he published a treatise on Oriental Mysticism, based on the Maksad-i-Aksa of Aziz ibn Mohammad Nafasi. He was engaged in 1860 to join the survey of Sinaï, undertaken by the Palestine Exploration Fund, and followed up this work in the next year by exploring the desert of El-Tih in company with Charles Upham (1846–1874). They completed this journey on foot and without escort, making friends among the Bedouin, to whom Palmer was known as “Abdallah Effendi.” After a visit to the Lebanon and to Damascus, where he took the acquaintance of Sir Richard Burton, then consul there, he returned to England in 1861 by way of Constantinople and Vienna. At Vienna he met Arminius Vambery. The results of this expedition appeared in the Desert of the Exodus (1871), in a report published in the Journal of the Palestine Exploration Fund (1871); and in an article on the Secret Sects of Syria in the Quarterly Review (1873). In the close of the year 1871 he became Lord Almoner's Professor of Arabic at Cambridge, married, and settled down to teaching. His salary was small, and his affairs were further complicated by the long illness of his wife, who died in 1878. In 1881, two years after his second marriage, he left Cambridge, and joined the staff of the Standard newspaper to write on non-political subjects. He was called to the English bar in 1874, and early in 1882 he was asked by the government to go to the East and assist the Egyptian expedition by his influence over the Arabs of the desert El-Tih. He was instructed, apparently, to prevent the Arab sheikhs from joining the Egyptian rebels and to secure their non-interference with the Suez Canal. He informed the Egyptian government that it was safest to leave the desert to Suez—an exploit of singular boldness—and was highly successful in his negotiations with the Bedouin. He was appointed interpreter-in-chief to the force in Egypt, and from Suez he was again sent into the desert with Captain William John Gill and Flag-Lieutenant Harold Charrington to procure camels and gain the allegiance of the sheikhs by considerable presents of money. On this journey he and his companions were led into an ambush and murdered (August 1882). Their remains, recovered after the war by the efforts of Sir Charles (then Colonel) Warren, now lie in St Paul's Cathedral.

Palmer's highest qualities appeared in his travels, especially in their arduous journeys. The best known of his scholarly writings is a work of considerable learning which is not only defrayed in the works he wrote in Persian and other Eastern languages than in his English books, which were generally written under pressure. His scholarship was wholly Eastern in character, and lacked the critical qualities of the modern school of Oriental learning in Europe. All his works show a great linguistic range and a very versatile talent; but he left no permanent literary monument worthy of his powers. His chief writings are The Desert of the Exodus (1871), Poems of Bekh Ed Din (1870–1877), Arabic Grammar (1874), History of Jerusalem (1871), by Benjamin Palmer—the latter were the part taken from Arabic sources; Persian Dictionary (1870) and English and Persian Dictionary (posthumous, 1883); translation of the Koran (1886) for the Sacred Books of the East series, a spirited but not very accurate rendering. He also did good service in editing the Name Lists of the Palestine Exploration.

PALMER, ERASTUS DOW (1817–1904), American sculptor, was born at Pomper, New York, on the 2nd of April 1817. In his leisure moments as a carpenter he started by carving portraits in cameos, and then began to model in clay with much success. Among his works are: “The White Captive” (1838) in the Metropolitan Museum of Art, New York; “Peace in Bondage” (1863); “Angel at the Sepulchre” (1863), Albany, New York; a bronze statue of Chancellor Robert R. Livingston (1874), in the State Capitol, Albany, N.Y.; “The Statue of Liberty” (1885), New York.

He died in Albany on the 6th of March 1904. His son, Walter Launt Palmer (b. 1854), who studied art under Carolus-Duran in Paris, became a member of the National Academy of Design (1897); and is best known for his paving of snow scenes.

PALMER, GEORGE (1818–1897). British biscuit-manufacturer, was born on the 8th of January 1818, at Long Sutton, Somersetshire, where his family had been yeoman-farmers for several generations. The Palmers were Quakers, and George Palmer was educated at the school of the Society of Friends at Sidcot, Somersetshire. About 1832 he was apprenticed to a miller and confectioner at Taunton, and in 1841, in conjunction with Thomas Huntley, set up as a biscuit-manufacturer at Reading. By the application of steam-machinery to biscuit-manufacture the firm of Huntley & Palmer in a comparatively short time built up a very large business, of which on the death of Huntley in 1857 George Palmer and his two brothers, Samuel and William Isaac Palmer, became proprietors. In the same year George...
PALMER, J. McAULEY—PALMERSTON

Palmer was elected mayor of Reading, and from 1878–1885 he was a Liberal member of Parliament for the town. He died at Reading, to which he had been a most generous benefactor, on the 19th of August 1887. His son, Sir George William Palmer (b. 1837) and Sir Walter Palmer (b. 1858), displayed a like munificence, particularly in connexion with University College, London. Sir George William Palmer, besides being mayor of Reading, represented the town in Parliament as a Liberal. Sir Walter Palmer, who was created a baronet in 1904, became Conservative member for Salisbury in 1900.

PALMER, JOHN McAULEY (1817–1900), American soldier and political leader, was born at Eagle Creek, Kentucky, on the 13th of September 1817. In 1831 his family removed to Illinois, and in 1839 he was admitted to the bar in that state. He was a member of the state constitutional convention of 1847. In 1852–1855 he was a Democratic member of the state Senate, but joined the Republican party upon its organization and became one of its leaders in Illinois. He was a delegate to the Republican national convention in 1856 and a Republican presidential elector in 1860. In 1861 he was a delegate to the peace convention in Washington. During the Civil War he served in the Union army, rising from the rank of colonel to that of major-general in the volunteer service and taking part in the capture of New Madrid and Island No. 10, in the battles of Stone River and Chickamauga, and, under Thomas, in the Atlanta campaign. He was governor of Illinois from 1869 to 1873. In 1872 he joined the Liberal-Republicans, and eventually returned to the Democratic party.

In 1861–1867 he was a Democratic member of the United States Senate. In 1866 he was nominated for the presidency, by the “Gold-Democrats,” but received no electoral votes. He died at Springfield, Illinois, on the 23rd of September 1900.

PALMER, RAY (1836–1887), American clergyman and hymn-writer, was born in Little Compton, Rhode Island, on the 12th of November 1836. He graduated at Yale College in 1859, and in 1852 was licensed to preach by the New Haven West Association of Congregational Ministers. In 1853–1856 he was pastor of the Central Congregational Church of Bath, Maine, and in 1856–1866 of the First Congregational Church of Albany, New York; and from 1866 to 1878 was corresponding secretary of the American Congregational Union. He died on the 20th of March 1887 in Newark, New Jersey, where, from 1881 to 1884 he had been assistant pastor of the Belleville Avenue Congregational Church. His most widely known hymn, beginning “My faith looks up to Thee, Thou Lamb of Calvary,” was written in 1850, was set to the tune “Olive” by Lowell Mason, and has been translated into many languages; his hymn beginning “Jesus, these eyes have never seen” (1858) is also well-known.

Among the hymns translated by him are those beginning: “O Christ, King of Glory” (by George W. Tabor); “Come Holy Ghost in love” (by Robert II. of France); “Jesus, thou Joy of loving hearts” (by Bernard of Clairvaux); and “O Bread to pilgrims given” (from the Latin). Other hymns (some of them translations from those written collected in his Complete Set of Works (1876), followed in 1880 by Voices of Hope and Gladness. He also wrote Spiritual Improvement (1839), republished in 1851 as Closet Hours; Hints on the Formation of Religious Opinions (1860), and Earnest Words on True Success in Life (1873).

PALMER, SAMUEL (1805–1881), English landscape painter and etcher, was born in London on the 27th of January 1805. He was delicate as a child, but in 1819 he exhibited both at the Royal Academy and the British Institution; and shortly afterward went with his son, John Linnell, who introduced him to Varley, Mulready, and, above all, to William Blake, whose strange and mystic genius had the most powerful effect on Palmer’s art. An illness led to a residence of seven years at Shoreham in Kent, and the characteristics of the scenery of the district are constantly recurrent in his works. Among the more important productions of this time are the “Bright Cloud” and the “Skylark,” paintings in oil, which was Palmer’s usual medium in earlier life. In 1830 he married a daughter of Linnell. The wedding tour was to Italy, where he spent over two years in study. Returning to London, he was in 1833 elected an associate and in 1834 a full member of the Royal Academy, and in 1837 he was elected a member of the Society of Painters in Water Colours, a method to which he afterwards adhered in his painted work. His productions are distinguished by an excellent command over the forms of landscape, and by mastery of rich, glowing and potent colouring. Among the best and most important paintings executed by Palmer during his later years was a noble series of illustrations to Milton’s L’Allegro and Il Penseroso. In 1853 the artist was elected a member of the English Etching Club. Considering his reputation and success in this department of art, his plates are few in number. Their virtues are not those of a rapid and vivid sketch; they aim rather at truth and completeness of tonality, and embody many of the characteristics of other modes of engraving—of mezzotint, of line, and of woodcut. Readily accessible and sufficiently representative plates may be studied in the “Early Floughman,” in Etching and Etchers (1st ed.), and the “Herdsmen’s Cottage,” in the third edition of the same work. In 1861 Palmer removed to Reigate, where he died on the 24th of May 1881.

One of his latest efforts was the production of a series of etchings to illustrate his English metrical version of Virgil’s Eclogues, which was published in 1883, illustrated with reproductions of the artist’s water-colours and with etchings, of which most were completed by his son, A. H. Palmer.

PALMER, a township of Hampden county, Massachusetts, U.S.A. Pop. (1910 U.S. census) 8610. It has an area of about 31 sq. m. of broken hill country. Its chief village, also named Palmer, about 15 m. east of Springfield, is on the Chicopee river, is served by the Boston & Albany and the Central Vermont railways, and by an electric line to Springfield, and has varied manufactures; the other villages are Thoms, Bondsville, and Three Rivers. The principal manufactures are cotton goods, carpets and wire goods. Palmer was originally settled in 1716, but received a notable accession of population from a large Scotch-Irish colony which went from Ulster to Boston in 1718. Their settlement was followed, apparently, by immigration from Ireland in 1777. In 1752 the plantation was incorporated as a “district,” and under a general state law of 1775 gained the legal rights of a township. Palmer was a centre of disaffection in the time of the Shays Rebellion.

PALMER, a pilgrim who as a sign or token that he had made pilgrimage to Palestine carried a palm-branch attached to his staff, or more frequently a cross made of two strips of palm-leaf fastened to his hat. The word is frequently used as synonymous with “pilgrim” (see Pilgrimage). The name “palm” or “pilgrim-worn” is often given to many kinds of hairy caterpillars, specifically to that of the destructive tined moth, Ypsilophus pometella. The name is either due to the English use of “palm” for the blossom or catkin of the willow-tree, to which the caterpillars bear some resemblance, or to the wandering pilgrim-like habits of such caterpillars. Artificial flies used in angling, covered with bristling hairs, are known also as “palmers” or “hackles.”

PALMERSTON, HENRY JOHN TEMPLE, 3RD VISCOUNT (1784–1865), English statesman, was born at Broadlands, near Romsey, Hants, on the 20th of October 1784. The Irish branch of the Temple family, from which Lord Palmerston descended, was very distantly related to the great English house of the same name, but these Irish Temples were not without distinction. In the reign of Elizabeth they had furnished a secretary to Sir Philip Sidney, and Essex in Sir William Temple (1555–1652), afterwards provost of Trinity College, Dublin, whose son, Sir John Temple (1600–1677), was master of the rolls in Ireland. The latter’s son, Sir William Temple (g.v.), figured as one of the ablest diplomatists of the age. From his younger brother, Sir John Temple (1632–1704), who was speaker of the Irish House of Commons, Lord Palmerston descended. The eldest son of the speaker, Henry, 1st Viscount Palmerston (c. 1673–1757), was created a peer of Ireland on the 12th of March 1723, and was
succeeded by his grandson, Henry the second viscount (1739-1802), who married Miss Mary Mee (d. 1803), a lady celebrated for her beauty.

The second viscount's eldest son, Henry John, is mentioned by Lady Elliot in her correspondence as a boy of singular vivacity and energy. These qualities adhered to him through life, and he had scarcely left Harrow, at the age of eighteen, when the death of his father (April 17, 1802) raised him to the Irish peerage. It was no doubt owing to his birth and connexions, but still more to his own talents and character, that Lord Palmerston was thrown at a very early age into the full stream of political and official life. Before he was four-and-twenty he had stood two contested elections for the university of Cambridge, at which he was defeated, and he entered parliament for a pocketborough, Newtown, Isle of Wight, in June 1807. Through the interest of his guardians Lord Malmsbury and Lord Chichester, the duke of Portland made him one of the junior lords of the Admiralty on the formation of his administration in 1807. A few months later he delivered his maiden speech in the House of Commons in defence of the expedition against Copenhagen, which he conceived to be justified by the known designs of Napoleon on the Danish court. This speech was so successful that when Perceval formed his government in 1809, he proposed to this young man of five-and-twenty to take the chair of the exchequer. Lord Palmerston, however, preferred the less important office of secretary-at-war, charged exclusively with the financial business of the army, without a seat in the cabinet, and in this position he remained, without any signs of an ambitious temperament or of great political abilities, for twenty years (1809-1828). During the whole of that period Lord Palmerston was chiefly known as a man of fashion, and a subordinate minister without influence on the general policy of the cabinets he served. Some of the most humorous poetical pieces in the New Whig Guide were from his pen, and he was entirely devoted, like his friends Peel and Croker, to the Tory party of that day. Lord Palmerston never was a Whig, still less a Radical; he was a statesman of the old English aristocratic type, liberal in his sentiments, favourable to the march of progress, but entirely opposed to the claims of democratic government.

In the later years of Lord Liverpool's administration, after the death of Lord Londonderry in 1822, strong dissensions existed in the cabinet. The Liberal section of the government was gaining ground. Canning became foreign minister and leader of the House of Commons. Huskisson began to advance a scheme to apply the doctrine of free trade. Roman Catholic emancipation was an open question. Although Lord Palmerston was not in the cabinet, he cordially supported the measures of Canning and his friends. Upon the death of Lord Liverpool, Canning was called to the head of affairs; the Tories, including Peel, withdrew their support, and an alliance was formed between the Liberal members of the late ministry and the Whigs. In this combination the chancellorship of the exchequer was first offered to Lord Palmerston, who accepted it, but this appointment was frustrated by the king's intrigue with Herries, and Palmerston was content to remain secretary-at-war with a seat in the cabinet, which he now entered for the first time. The Canning administration ended in four months by the death of its illustrious chief, and was succeeded by the feeble ministry of Lord Goderich, which barely survived the year. But the "Canningites," as they were termed, remained, and the duke of Wellington hastened to include Palmerston, Huskisson, Charles Grant, Lamb (Lord Melbourne) and Dudley in his government. A dispute between the duke and Huskisson soon led to the resignation of Lord minister, and his friends felt bound to follow his fate. In the spring of 1830 Palmerston found himself in opposition. From that moment he appears to have directed his attention closely to foreign affairs; indeed he had urged on the duke of Wellington a more active interference in the affairs of Greece; he had made several visits to Paris, where he foresaw with great accuracy the impending revolution; and on the 1st of June 1829 he made his first great speech on foreign affairs. Lord Palmerston was no orator; his language was unstudied, and his delivery somewhat embarrassed; but he generally found words to say the right thing at the right time, and to address the House of Commons in the language best adapted to the capacity and the temper of his audience. An attempt was made by the duke of Wellington in September 1830 to induce Palmerston to re-enter the cabinet, which he refused to do without Lord Lansdowne and Lord Grey, and from that time forward he may be said to have associated his political fortunes with those of the Whig party. It was therefore natural that Lord Grey should place the department of foreign affairs in his hands upon the formation of the great ministry of 1830, and Palmerston entered with zeal on the duties of an office over which he continued to exert his powerful influence, both in and out of office, for twenty years.

The revolution of July 1830 had just given a strong shock to the existing settlement of Europe. The kingdom of the Netherlands was rent asunder by the Belgian revolution; Portugal was the scene of civil war; the Spanish succession was about to open and place an infant princess on the throne. Poland was in arms against Russia, and the northern powers formed a closer alliance, threatening to the peace and the liberties of Europe. In presence of these varied dangers, Lord Palmerston was prepared to act with spirit and resolution and the great man of the moment. The king of the Netherlands had appealed to the powers who had placed him on the throne to maintain his rights; and a conference assembled accordingly in London to settle the question, which involved the independence of Belgium and the security of England. On the one hand, the northern powers were anxious to defend the king of Holland; on the other hand a party in France aspired to annex the Belgian provinces. The policy of the British government was a close alliance with France, but an alliance based on the principle that no interests were to be promoted at variance with the just rights of others, or which could give to any other nation well-founded cause of jealousy. If the northern powers supported the king of Holland by force, they would encounter the resistance of France and England united in arms, if France sought to annex Belgium she would forfeit the alliance of England, and find herself opposed by the whole continent of Europe. In the end the policy of England prevailed; numerous difficulties, both great and small, were overcome by the conference, although on the verge of war, peace was maintained; and Prince Leopold of Saxe-Coburg was placed upon the throne of Belgium.

In 1833 and 1834, the youthful queens Donna Maria of Portugal and Isabella of Spain were the representatives and the hope of the constitutional party in those countries—assailed and hard pressed by their absolutist kinsmen Don Miguel and Don Carlos, who were the representatives of the male line of succession. Lord Palmerston conceived and executed the plan of a quadruple alliance of the constitutional states of the West to serve as a counterpoise to the northern alliance. A treaty for the pacification of the Peninsula was signed in London on the 22nd of April 1834; and, although the struggle was somewhat prolonged in Spain, it accomplished its object. France, however, had been a reluctant party to this treaty. She never executed her share in it with zeal or fidelity. Louis Philippe was accused of secretly favouring the Carlists, and he positively refused to be a party to direct interference in Spain. It is probable that the hesitation of the French court on this question was one of the causes of the extreme personal hostility Lord Palmerston never ceased to show towards the king of France down to the end of his life, if indeed that sentiment had not taken its origin at a much earlier period. Nevertheless, at this same time (June 1834) Lord Palmerston wrote that "Paris is the pivot of my foreign policy." M. Thiers was at that time in office. Unfortunately these differences, growing out of the opposite policies of the two countries at the court of Madrid, increased in each succeeding year; and a constant but sterile rivalry was kept up, which ended in results more or less humiliating and injurious to both nations.

The affairs of the East interested Lord Palmerston in the highest degree. During the Greek War of Independence he had strenuously supported the claims of the Hellespont against the

"Turks and the execution of the Treaty of London. But from 1836 the defence of the Ottoman Empire became one of the cardinal objects of his policy. He believed in the regeneration of Turkey. "All that we hear," he wrote to Bulwer (Lord Dalling), "about the decay of the Turkish Empire, and its being a dead body or a sapless trunk, and so forth, is pure unadulterated nonsense." The two great aims he had in view were to prevent the establishment of Russia on the Bosporus and of France on the Nile, and he regarded the maintenance of the authority of the Porte as the chief barrier against both these aggressions. Against Russia he had long maintained a suspicious and hostile attitude. He was a party to the publication of the "Portfolio" in 1834, and to the mission of the "Vixen" to force the blockade of Circassia about the same time. He regarded the treaty of Unkia Skelessi which Russia extorted from the Porte in 1832, when she came to the relief of the sultan after the battle of Konieh, with great jealousy; and, when the power of Mehemet Ali in Egypt appeared to threaten the existence of the Ottoman dynasty, he succeeded in effecting a combination of all the powers who signed the celebrated collective note of the 27th of July 1839, pledging them to maintain the independence and integrity of the Turkish Empire as a security for the peace of Europe. On two former occasions, in 1833 and in 1835, the policy of Lord Palmerston, who proposed to afford material aid to the Porte against the pasha of Egypt, was overruled by the cabinet; and again, in 1839, when Baron Brunnow first proposed the active interference of Russia and England, the offer was rejected. But in 1840 Lord Palmerston returned to the charge and prevailed. The moment was critical, for Mehemet Ali had occupied Syria and won the battle of Nazib against the Turkish forces, and on the 1st of July 1839 the sultan Mohammed expired. The Egyptian forces occupied Syria, and threatened Egypt; and Lord Ponsonby, then British ambassador at Constantinople, vehemently urged the necessity of crushing so formidable a rebellion against the Ottoman power. But, though his ambassador had signed the collective note in the previous year, deemed to be a party to measures of coercion against the pasha of Egypt, Palmerston, irritated at his Egyptian policy, flung himself into the arms of the northern powers, and the treaty of the 15th of July 1840 was signed in London without the knowledge or concurrence of France. This measure was not taken without great hesitation, and strong opposition on the part of several members of the British cabinet. Lord Palmerston himself declared in a letter to Lord Melbourne that he should quit the ministry if his policy was not adopted; and he carried his point. The bombardment of Beirut, the fall of Acre, and the total collapse of the boasted power of Mehemet Ali followed in rapid succession, and before the close of the year Lord Palmerston's policy, which had convulsed and terrified Europe, was triumphant, and the author of it was regarded as one of the most powerful statesmen of the age. At the same time, though acting with Russia in the Levant, the British government engaged in the affairs of Afghanistan to defeat her intrigues in Central Asia, and a contest with China was terminated by the conquest of Chusan, afterwards exchanged for the island of Hong-Kong.

Within a few months Lord Melbourne's administration came to an end (1841), and Lord Palmerston remained for five years out of office. The crisis was past, but the change which took place by the substitution of M. Guizot for M. Thiers in France, and of Lord Aberdeen for Lord Palmerston in England, was a fortunate event for the peace of the world. Lord Palmerston had adopted the opinion that peace with France was not to be relied on, and indeed that war between the two countries was sooner or later inevitable. Lord Aberdeen and M. Guizot inaugurated a different policy; by mutual confidence and friendly offices they entirely succeeded in restoring the most cordial understanding between the two governments, and the irritation which Lord Palmerston had inflamed gradually subsided. During the administration of Sir Robert Peel, Lord Palmerston led a retired life, but he attacked with characteristic bitterness the Ashburton treaty with the United States, which closed successfully some other questions he had long kept open. In all these transactions, whilst full justice must be done to the force and patriotic vigour which Lord Palmerston brought to bear on the questions he took in hand, it was but too apparent that he imported into them an amount of passion, of personal animosity, and imperious language which rendered him in the eyes of the queen and of his colleagues a dangerous minister. On this ground, when Lord John Russell attempted, in December 1845, to form a ministry, the combination failed because Lord Grey refused to join a government in which Lord Palmerston should resume the direction of foreign affairs. A few months later, however, this difficulty was surmounted; the Whigs returned to power, and Palmerston to the foreign office (July 1846), with a strong assurance that Lord John Russell should exercise a strict control over his proceedings. A few days sufficed to show how vain was this expectation. The French government regarded the appointment of Palmerston as a certain sign of renewed hostilities, and they availed themselves of a despatch in which Palmerston had put forward the name of a Coburg prince as a candidate for the hand of the young queen of Spain, as a justification for a departure from the engagements entered into between M. Guizot and Lord Aberdeen. However little the conduct of the French government in this transaction of the Spanish marriages can be vindicated, it is certain that it originated in the belief that in Palmerston France had a restless and subtile enemy. The efforts of the British minister to defeat the French marriages of the Spanish princesses, by an appeal to the treaty of Utrecht and the other powers of Europe, were wholly unsuccessful; France won the game, though with no small loss of honourable reputation.

The revolution of 1848 spread like a conflagration through Europe, and shook every throne on the Continent except those of Russia, Spain, and Belgium. Palmerston sympathized, or was supposed to sympathize, openly with the revolutionary party abroad. No state was regarded by him with more deep-seated suspicion than Austria. Yet his opposition to Austria was chiefly based upon her occupation of a great part of Italy and her Italian policy, for Palmerston maintained that the existence of Austria as a great power north of the Alps was an essential element in the system of Europe. Antipathies and sympathies had a large share in the political views of Lord Palmerston, and his sympathies had ever been passionately awakened by the cause of Italian independence. He supported the Sicilians against the king of Naples, and even allowed arms to be sent them from the arsenal at Woolwich; and, although he had endeavoured to restrain the king of Sardinia from his rash attack on the superior forces of Austria, he obtained for him a reduction of the penalty of defeat. Austria, weakened by the revolution, sent an envoy to London to request the mediation of England, based on a large cession of Italian territory; Lord Palmerston rejected the terms he might have obtained for Piedmont. Ere long the reaction came; this straw-fire of revolution burnt itself out in a couple of years. In Hungary, the civil war, which had thundered at the gates of Vienna, was brought to a close by Russian intervention. Prince Schwarzenberg assumed the government of the empire with dictatorial power; and, in spite of what Palmerston termed his "judicious bottle-holding," the movement he had encouraged and applauded, but to which he could give no material aid, was everywhere subdued. The British government, or at least Palmerston as its representative, was regarded with suspicion and resentment by every power in Europe, except the French republic; and even that was shortly afterwards to be alienated by Palmerston's attack on Greece.

This state of things was regarded with the utmost annoyance by the British court and by most of the British ministers. Palmerston had on many occasions taken important steps without their knowledge, which they disapproved. Over the Foreign Office he asserted and exercised an arbitrary dominion, which the feeble efforts of the premier could not control. The queen and the prince consort (see VICTORIA, QUEEN) did not conceal their indignation at the position in which he had placed them with all the other courts of Europe. When Kossuth, the
Palmerston

 Hungarian leader, landed in England, Palmerston proposed to receive him at Broadlands, a design which was only prevented by a peremptory claim of the subject; and in 1850 he took advantage of Don Pacifico’s very questionable election to the Hellenic government to organize an attack on the little kingdom of Greece. Greece being a state under the joint protection of three powers, Russia and France protested against its coercion by the British fleet, and the French ambassador temporarily left London, which promptly led to the termination of the affair. But it was taken up in parliament with great warmth. After a memorable debate (June 17), Palmerston’s policy was condemned by a vote of the House of Lords. The House of Commons was moved by Roebuck to reverse the sentence, which it did (June 29) by a majority of 46, after having heard from Palmerston the most eloquent and powerful speech ever delivered by him, in which he sought to vindicate, not only his claims on the Greek government for Don Pacifico, but his entire administration of foreign affairs. It was in this speech, which lasted five hours, that Palmerston made the well-known declaration that a British subject—Civis Romanus sum—ought everywhere to be protected by the strong arm of the British government against injustice and wrong done, notwithstanding this parliamentary triumph, there were not a few of his own colleagues and supporters who condemned the spirit in which the foreign relations of the Crown were carried on; and in that same year the queen addressed a minute to the prime minister in which she recorded her dissatisfaction at the manner in which Lord Palmerston evaded the obligation to submit his measures for the royal sanction as failing in sincerity to the Crown. This minute was communicated to Palmerston, who did not resign upon it. These various circumstances, and many more, had given rise to distrust and uneasiness in the cabinet, and these feelings reached their climax when Palmerston, on the occurrence of the coup d'état by which Louis Napoleon made himself master of France, expressed to the French ambassador in London, without the concurrence of his colleagues, his personal approval of that act. Upon this Lord John Russell advised his dismissal from office (Dec. 1851). Palmerston speedily avenged himself by turning out the government on a militia bill; but although he survived for many years, and twice filled the highest office in the state, his career as foreign minister ended for ever, and he returned to the foreign office no more. Indeed, he assured Lord Aberdeen, in 1853, that he did not wish to resume the seals of that department. Notwithstanding the zeal and ability which he had invariably displayed as foreign minister, it had long been felt by his colleagues that his eager and frequent interference in the affairs of foreign countries, his imperious temper, the extreme acerbity of his language abroad, of which there are ample proofs in his published correspondence, and the evasions and artifices he employed to carry his points at home, rendered him a dangerous representative of the foreign interests of the country. But the lesson of his dismissal was not altogether lost on him. Although his great reputation was chiefly earned as a foreign minister, it may be said that the last ten years of his life, in which he filled other offices, were not the least useful or dignified portion of his career.

Upon the formation of the cabinet of 1853, which was composed by the junction of the surviving followers of Sir Robert Peel with the Whigs, under the earl of Aberdeen, Lord Palmerston accepted with the best possible grace the office of secretary of state for the home office, nor was he ever chargeable with the slightest attempt to undermine that Government. At one moment he withdrew from it, because Lord John Russell persisted in presenting a project of reform which appeared to him entirely out of season; and he advocated, with reason, measures of greater energy on the approach of war, which might possibly, if they had been adopted, have averted the contest with Russia. As the difficulties of the Crimean campaign increased, it was not Lord Palmerston but Lord John Russell who broke up the government by refusing to meet Roebuck’s motion of inquiry. Palmerston remained faithful and loyal to his colleagues in the hour of danger. Upon the resignation of Lord Aberdeen and the duke of Newcastle, the general sentiment of the House of Commons and the country called Palmerston to the head of affairs, and he entered, on the 5th of February 1855, upon the high office, which he retained, with one short interval, to the day of his death. Palmerston was in the seventy-first year of his life when he became prime minister of England.

A series of fortunate events followed his accession to power. In March 1855 the death of the emperor Nicholas removed his chief antagonist. In September Sevastopol was taken. The administration of the British army was reformed by a consolidation of offices. In the following spring peace was signed in Paris. Never since Pitt had a minister enjoyed a greater share of popularity and power, and, unlike Pitt, Palmerston had the prestige of victory in war. He was assailed in parliament by the eloquence of Gladstone, the sarcasms of Disraeli, and the bitter invective of the Lancashire Radicals, but the country was with him. Defeated by a hostile combination of parties in the House of Commons on the question of the Crimean war in 1857 and the alleged insult to the British flag in the seizure of the lorcha “Arrow,” he dissolved parliament and appealed to the nation. The result was the utter defeat of the extreme Radical party and the return of a more compact Liberal majority. The great events of the succeeding years, the Indian Mutiny, and the invasion of Italy by Napoleon III, belong rather to the general history of the times than to the life of Palmerston; but it was fortunate that a strong and able government was at the head of affairs. Lord Derby’s second administration of 1858 lasted but a single year, Palmerston having casually been defeated on a measure for removing conspiracies to murder abroad from the class of misdemeanour to that of felony, which was introduced in consequence of Orsini’s attempt on the life of the emperor of the French. But in June 1859 Palmerston returned to power, and it was on this occasion that he proposed to Cobden, one of his most constant opponents, to take office, and on the refusal of that gentleman, Mr. Milner Gibson was appointed to the board of trade, although he was the prime mover of the defeat of the government on the Conspiracy Bill. Palmerston had learnt by experience that it was wiser to conciliate an opponent than to attempt to crush him, and that the imperious tone he had sometimes adopted in the House of Commons, and his supposed obsequiousness to the emperor of the French, were the causes of the temporary reverse he had sustained. Although Palmerston approved the objects of the French invasion of Italy in so far as they went to establish Italian independence, the annexation of Savoy and Nice to France was an incident which revived his old suspicions of the good faith of the French emperor. About this time he expressed to the duke of Somerset his conviction that Napoleon III. “had at the bottom of his heart a deep and unextinguishable desire to subdue and punish England,” and that war with France was a contingency to be provided against. The unprotected condition of the principal British fortresses and arsenals had long attracted his attention, and he succeeded in inducing the House of Commons to vote nine millions for the fortification of those important points.

In 1856 the projects for cutting a navigable canal through the Isthmus of Suez was brought forward by M. de Lesseps, and resisted by Palmerston with all the weight he could bring to bear against it. He did not foresee the advantages to be derived by British commerce from this great work, and he was strongly opposed to the establishment of a powerful French company on the soil of Egypt. The concession of land to the company was reduced by his intervention, but in other respects the work proceeded and was accomplished. It may here be mentioned, as a remarkable instance of his foresight, that
Palmerston told Lord Malmesbury, on his accession to the foreign office in 1861, that the chief reason of his opposition to the canal was that it would involve the annexation of a region which was then in the control of the Sultan, and that the Sultan would be thus enabled, in case of a war, to interpose against the proposed canal in the name of the sultan. Palmerston's position was that Great Britain, as the first mercantile state, and that most closely connected with the East, would be the power most interested in it; that England would therefore be drawn irresistibly into a more direct interference in Egypt, which it was desirable to avoid because England had already enough upon her hands, and because intervention might lead to a rupture with France. He therefore preferred that no such line of communication should be opened.

Upon the outbreak of the American Civil War in 1861, Lord Palmerston acknowledged that it was the duty of the British government to stand aloof from the fray; but his own opinion led him rather to desire than to avert the rupture of the Union, which might have been the result of a refusal on the part of England and France to recognize a blockade of the Southern ports, which was notoriously imperfect, and extremely prejudicial to the interests of Europe. The cabinet was not of this opinion, and, although the belligerent rights of the South were promptly recognized, the neutrality of the Government was strictly observed. When, however, the Southern envoys were taken by force from the "Trent," a British packet, Palmerston did not hesitate a moment to insist upon a full and complete reparation for so gross an infraction of international law. But the difficulty with the American government over the "Alabama" and other vessels, fitted out in British ports to help the Southern cause, was only settled at last (see Alabama Arbitration) by an award extremely onerous to England.

The last transaction in which Palmerston engaged arose out of the attack by the German Confederation, and its leading states Austria and Prussia, on the kingdom of Denmark and the duchies of Schleswig and Holstein. There was but one feeling in the British public and the nation as to the dishonest character of that unprovoked aggression, and it was foreseen that Austria would ere long have reason to repent her share in it. Palmerston endeavoured to induce France and Russia to concur with England in maintaining the Treaty of London, which had guaranteed the integrity of the Danish dominions. But those powers, for reasons of their own, stood aloof, and the conference held in London in 1864 was without effect. A proposal to send the British fleet into the Baltic was overruled, and the result was that Denmark was left to her own resources against her formidable opponents. In the following year, on the 18th of October 1865, Lord Palmerston expired at Brocket Hall, after a short illness, in the eighty-first year of his age. His remains were laid in Westminster Abbey.

Although there was much in the official life of Lord Palmerston which inspired distrust and alarm to men of a less ardent and contentious temperament, he had a lofty conception of the strength and the duties of England, he was the irreconcilable enemy of slavery, injustice and oppression, and he laboured with inexhaustible energy for the dignity and security of the Empire. In private life his gaiety, his buoyancy, his high breeding, made even his political opponents forget their differences; and even the warmest alterations on public affairs were merged in his large hospitality and cordial social relations. In this respect he was aided with consummate ability by the tact and grace of Lady Palmerston, the widow of the 5th Earl Cowper, whom he married at the close of 1839, and who died in 1869. She devoted herself with enthusiasm to all her husband's interests and pursuits, and she made his house the most attractive centre of society in London, if not in Europe. They had no children, and the title became extinct, the property descending to Lady Palmerston by entail to W. F. Cowper-Temple, afterwards Baron Mount Temple, and then to her grandson Evelyn Ashley (1856-1907) son of her daughter, who married the 7th earl of Shaftesbury—was Lord Palmerston's private secretary from 1858 to 1865.

The Life of Lord Palmerston, by Lord Dalling (2 vols., 1870), with valuable selections from the minister's autobiographical diaries and private correspondence, only came down to 1847, and was completed by Evelyn Ashley (vol. iii., 1874; iv., 1876). The work was re-edited by Mr. Ashley, in two volumes (1879), the standard biography. The Life by Lloyd Sanders (1888) is an excellent shorter work.

PALMERSTON, the chief town of the Northern Territory of South Australia, in Palmerston county, on the E. shore of Port Darwin, 2000 m. direct N.N.W. of Adelaide. The town stands 60 ft. above the level of the sea, by which it is almost surrounded. There are a government house, a town hall, and an experimental nursery garden. Palmerston has a magnificent harbour, accessible to ocean-going vessels, and the jetty is connected by rail with Playford, 146 m. distant. Cool breezes blow almost continuously throughout the year. The mean annual rainfall is 62-21 in. Pop. (1901), 1737, mostly Chinese.

PALMETTO, in botany, a popular name for Sabal palmetto, the Palmetto palm, a native of the southern United States, especially in Florida. It has an erect stem, 20 to 80 ft. high and deeply cut fan-shaped leaves, 5 to 8 ft. long; the fruit is a black drupe ¼ to ½ in. long. The trunk makes good piles for wharves, &c., as the wood resists the attacks of borers; the leaves are used for thatching. The palm is grown as a pot-plant in greenhouses.

PALMISTRY, (from "palmist," one who studies the palm, and the Teutonic affix yr signifying "art"); also called CHIROMANCY, from χειρ, the hand, and μαίνειν, divination). The desire to learn what the future has in store is nearly as old as the sense of responsibility in mankind, and has been the parent of many empirical systems of fortune-telling, which profess to afford positive knowledge whereby the affairs of life may be regulated, and the dangers of failure foretold. Most of these systems come into the category of occult pursuits, as they are the interpretations of phenomena on the ground of fanciful presumptions, by an appeal to unreal or at least unverifiable influences and relations.

One of the oldest of this large family of predictive systems is that of palmistry, whereby the various irregularities and flexion-folds of the skin of the hand are interpreted as being associated with mental or moral dispositions and powers, as well as with the current of future events in the life of the individual. How far back in prehistoric times this system has been practised it is impossible to say, but in China it is said to have existed 3000 years before Christ,1 and in Greek literature it is treated even in the most ancient writings as well-known belief. Thomas Blackwell2 has collected some Homeric references: a work by Melampus of Alexandria is extant in several versions. Ptolemy, Aristotle and Adamantius may also be named as having dealt with the subject; as also have the medical writers of Greece and Rome—Hippocrates, Galen and Paulus Aegineta, and in later times the Arabian commentators on these authors. From references which can be gathered from patristic writings it is abundantly evident that the belief in the mystical meaning of marks on the "organ of organs" was a part of the popular philosophy of their times.

After the invention of printing a very considerable mass of literature concerning this subject was produced during the 16th and 17th centuries. Praetorius, in his Ludicum chiro-

1 Gilman, in Contemporary Review (1905).
3 This book is worthy of note on account of the quaint and sarcastic humour of its numerous acrostic verses.

PALMITIC ACID—PALM SUNDAY

The best are those from Pompeii, Robert Fludd, John de Indagine, Taisnierius, Baptista dalla Forta, S. Cardan, Goechius, Codex, Talhoffer, Rothman, Ingebert, Pompomus Gauricus, and Tricassius Mantuanus. There are also early Hebrew works, of which one by Gedaliah is extant. An Indian literature is also said to exist. Some of these authors attempt to separate the physiognomical part of the subject (Chirognomia) from the astrological (Chiriontia); see especially Caspar Schott in Magia naturalis universalis, Baniberg, 1677. Since the middle of the 19th century, in spite of the enactments of laws in Britain and elsewhere against the practice, there has been a recrudescence of belief in palmistry, and a new literature has grown up differing little in essence from the older. The more important books of this series are K. G. Carus, Über Grund und Bedeutung der verschiedenen Formen der Hand, 1846; Landsberg, Die Handtellur (Posen, 1861); Adolf Desbarolles, Les Mystères de la main (1859); C. S. D’Arpentigny, Chirognomie, la science de la main (1865), of which an English version has been published by Heron Allen in 1886; G. Z. Gessmann, Kulturgeschichte der Handkunst (Berlin, 1885); Carvæus, De Dictum Handstriet (Dresden, 1893); R. Beamish, The Psychonomy of the Hand (1865); Frith and Allen, The Science of Palmistry (1883); Cotton, Palmistry and its practical uses (1890). Some of the older writers appealed to Scripture as supporting their systems, especially the texts Exod. xii. 16; Job xxxvii. 7; and Prov. iii. 16. A considerable amount of literature pro and con was devoted to this controversy in the 17th and 18th centuries.

At the present day palmistry is practised in nearly all parts of China. The criteria of judgment used there are referred to in the article by Professor H. A. Giles, already quoted. It is also extensively practised in India, especially by one caste of Brahmans, the Joshi. In Syria and Egypt the palmist can be seen plying his trade at the cafes; and among the Arabs there are chirologists who are consulted as to the probable success of enterprises. It is probably from their original Indian home that the traditional dukkeripen (fortune-telling) of the gypsies has been derived.

This system of divination has the charm of simplicity and definiteness, as an application of the "doctrine of signatures" which formed so extensive an element in the occult writings of the past six centuries. In the course of ages every detail has been brought under a formal set of rules, which only need mechanical application. There have been in past times considerable divergences in the practice, but at present there is a fairly uniform system in vogue. One school lays special stress on the general shape and outline of the hand. Corvæaeus enumerates 70 varieties, Pamphilus cuts them down to 6, John de Indagine to 27, and Tricassius Mantuanus raises them to 80. The characters of softness or hardness, dryness or moisture, &c., are taken account of in these classifications. The lines of cardinal importance are (1) the raceta or cross sulci, which isolate the hand from the forearm at the wrist, and which are the gauge of the health of the body; (2) the sulci which run from skin to sinew down to the fascia above the level of the anterior annular ligament. (2) The line which isolates the ball of the thumb, where the skin ceases to be tied to the front of the palmar fascia, is called the line of life. (3) A line starting above the head of the second metacarpal bone and crossing the hand to the middle of its ulnar border is the line of the head. (4) The transverse line below this which passes from the ulnar border a little above the level of the head of the fifth metacarpal and ends somewhere about the root of the index finger is the line of the heart. (5) The vertical line descending from the middle of the wrist to end about the base of the middle finger is the line of fortune. (6) The oblique line which begins at the wrist end of the line of life and descends towards the ulnar end of the line of the head is the line of the liver.

These lines isolate certain swellings or monticuli, the largest of which is (1) the ball of the thumb, called the mountain of Venus; (2) that at the base of the index finger is the mountain of Jupiter; (3) at the root of the middle finger is the mountain of Saturn, while those at the bases of ring and little finger are respectively the mountains of the (4) Sun and (5) of Mercury. Above the mountain of Mercury, and between the lines of head and heart is (6) the mountain of Mars, and above the line of the heart is (7) the mountain of the Moon. The relative sizes of these mountains have assigned to them their definite correlations with characters: the 1st with charity, love, libertinage; the 2nd with religion, ambition, love of honour, pride, superstition; the 3rd with wisdom, good fortune, prudence, or when deficient improvidence, ignorance, failure; the 4th when large makes for success, celebrity, intelligence, audacity, when small meanness or love of obscurity; the 5th indicates love of knowledge, industry, aptitude for commerce, and in its extreme forms on the one hand love of gain and dishonesty, on the other slackness and laziness. The 6th is related to degrees of courage, resolution, rashness or timidity; the 7th indicates sensitiveness, morality, good conduct, or immorality, overbearing temper and self-will.

The swellings on the palmar faces of the phalanges of the several fingers are also indicative, the 1st and 2nd of the thumb respectively, of the logical faculty and of the will; the 1st, 2nd and 3rd of the middle finger, of materialism, law and order, idealism; those of the middle finger, humanity, system, intelligence; of the ring finger, truth, economy, energy; and of the little finger, goodness, prudence, reflectiveness.

Over and above these there are other marks, crosses, triangles, &c., of which more than a hundred have been described and figured by different authors, each with its interpretation; and in addition the back of the hand has its ridges. The Chinese combine palmody with chiroscopy.

To the anatomist the roughnesses of the palm are of considerable interest. The folds are so disposed that the thick skin shall be capable of bending in grasping, while at the same time it requires to be tightly bound down to the skeleton of the hand, else the slipping of the skin would lead to insecurity of prehension, as the quilting or buttoning down of the covers of furniture by upholsterers keeps them from slipping. For this purpose the skin is strengthened by connecting fibres of white fibrous tissue to the deep layer of the dermis along the lateral and lower edges of the palmar fascia and to the sheaths of the flexor tendons. The folds, therefore, which are disposed for the purpose of making the grasp secure, vary with the relative lengths of the metacarpal bones, with the mutual relations of the sheaths of the tendons, and the edge of the palmar fascia, somewhat also with the insertion of the palmaris brevis muscle. The sulci are emphasized because the subcutaneous fat, which is copious in order to pad the skin for the purpose of firmness of holding, being restricted to the intervals between the lines along which the skin is tied down, makes these intervals project, and these are the monticuli. The swelling of the mountain of Venus is simply the indication of the size of the muscles of the ball of the thumb, and can be increased by their exercise. Similarly the hypothenar muscles for the little finger underlie the three ulnar marginal mountains, the sizes of which depend on their development and on the prominence of the pisiform bone.

That these purely mechanical arrangements have any psychic, occult or predictive meaning is a fantastic imagination, which seems to have a peculiar attraction for certain types of mind, and as there can be no fundamental hypothesis of correlation, its discussion does not lie within the province of reason.

PALMITIC ACID, n-Hexadecylic Acid, CH3(CH2)14CO2H, an organic acid found as a glyceride, palmityl, in all animal fats, and partly as glyceryde and partly uncombined in palm oil. The cetyl ester is spermatic, and the myricyl ester is largely present in beeswax. It is most conveniently obtained from olive oil, after removal of the oleic acid (q.v.), or from Japanese beeswax, which is its glyceride. Artifically it may be prepared by heating cetyl alcohol with soda lye to 270° or by fusing oleic acid with potassium hydrate.

PALM SUNDAY (Dominica palmarum), the Sunday before Easter, so called from the custom, still observed in the Roman Catholic Church, of blessing palm branches and carrying them in
procession in commemoration of Christ’s triumphal entry into Jerusalem. In the Western Church, Palm Sunday is counted as the first day of Holy Week, and its ceremonies usher in the series of services, culminating in those of Good Friday, which commemorate the Passion of the Lord.

The ceremonies on Palm Sunday as celebrated now in the Roman Catholic Church are divided in three distinct parts:

1. The solemn blessing of the palms, (2) the procession, (3) the mass.

Branches of palm, olive or sprouting willow (hence in England known as “palm”) having been placed before the altar, or at the Epitraxis, after Terce and the sprinkling of holy water, either in a purple cope or an alb without chasuble, proceed to bless them. The ceremony begins with the singing by the choir of the anthem Hosanna Filio David; the collect follows; then the singing of a lesson from Exodus xxv. by the subdeacon; then the Consecration, reciting antiphonally the conspiracy of the chief priests and Pharisees. And concluding with Christ’s prayer on Mt Olivet; then the Gospel, sung by the deacon in the ordinary way, followed by a continuation of the Holy Gospel” (Matt. xxv. and xxvi.). After this the priest blesses the palms in a series of prayers, that those who receive them “may be protected in soul and body,” and that “unto whatever place they may be brought the inhabitants of that place may obtain Thy benediction and all adversity be removed.”

The priest then sprinkles the palms thrice with holy water, saying the prayer Asperges me, &c., and also incenses them thrice. The principal of the clergy present then approaches and gives a palm to the celebrant, and to the other clergy, and to the subdeacon, and to the other clergy in order of rank, and lastly to the lay, all of whom receive the palms kneeling and kiss the palm and the hand of the celebrant. During the distribution antiphons are sung.

The deacon now turns to the people and says Procesus in pace, and the procession begins. It is headed by a trailer carrying a smoking torch supported by two acolytes with lighted tapers; the clergy next in order, the celebrant coming last with the deacon on his left, all carrying branches and singing antiphonally, so long as the procession lasts. The celebrant then at each time, sings the “Benedictus qui venit in nomine Domini: Hosanna in excelsis.” On returning to the church, two or four singers enter first and close the doors, then, turning towards the procession outside, sing the first two verses of the hymn “Gloria, laus et honor,” those outside repeating them, and so on till the hymn is finished. This done, the subdeacon strikes the door with the staff of the cross, when it is immediately opened, and the procession enters singing. The mass that follows, characterized by all the outward signs of sorrow proper to Palm Sunday, is in striking contrast with the joyful triumph of the procession.

In the Orthodox Church Palm Sunday (υφανσις or λαγη των βαλανις, λαγη βασιλειος, ο δ βασιλειος) is not included in Holy Week, but it is regarded as a joyful festival commemorating Christ’s triumphal entry into Jerusalem. There is no longer a procession; but the palms (in Russia willow twigs) are blessed, and are held by the worshippers during the service.

The earliest extant account of a liturgical celebration of Palm Sunday is that given in the Peregrinatio Silvae (Elesutheriae),1 which dates from the 4th century and contains a detailed account of the Holy Week ceremonies at Jerusalem by a Spanish lady of rank.

The actual festival began at one o’clock with a service in the church on the Mount of Olives; at three o’clock clergy and people went in procession, singing hymns, to the scene of the Ascension; two hours of prayer, singing and reading of appropriate Scriptures followed, until, at five, the arrival from the Greek church, telling how “the children with olive branches and palms go to meet the Lord, and cry: ‘Blessed is he that cometh in the name of the Lord’ gave the signal for the crowd to break up, and, carrying branches of olive and palm, to the gate the gospel quae vocant Dominus deditus est,” with cries of “Blessed is he that cometh in the name of the Lord!” to the Church of the Resurrection in Jerusalem, where a further service was held.

This celebration would seem to have been long established at Jerusalem, and there is evidence that in the 3rd and 4th centuries it had been copied in other parts of the East. In the West, however, it was not introduced until much later. To Pope Leo I. (d. 461) the present Dominica palmarum was known as Dominica passionis, Passion Sunday, and the Western Church treated it as a day, not of rejoicing, but of mourning. The earliest record in the West of the blessing of the palms and the subsequent procession is the liber ordinum of the West Gothic Church (published by Fétotin, Paris, 1904, pp. 178 sq.), which dates from the 6th century; this shows plainly that the ceremonial of the procession had been borrowed from Jerusalem.

As to how far, and at what period, it became common there is very little evidence. For England, the earliest record is the mention by Aldehelm, bishop of Sherborne (d. 700), in his De loudibus virginatis (cap. 30, Migne Patrol. Lat. 80, p. 128), of a sacrosancta palmarum solennitas, which probably means a procession, since he speaks of the Benedictus qui venit, &c., being sung antiphonally. As the middle ages advanced the procession became more and more popular and increasingly a dramatic representation of the triumphal progress of Christ, the bishop riding on an ass or horse, as in the East. Flowers, too, were blessed, as well as palms and willow, and carried in the procession (hence the name pascha floridum, dominica florum et ramarum, les pâques fleuries).

The origin of the ceremony of blessing the palms is more obscure. It is not essential to the dramatic character of the celebration and for centuries seems to have formed no usual part of it. Herr Drews (Pfingst, p. 175, XXL, 7, 66) may have been misled by the idea of an entirely separate and pagan origin. It is significant that olive and willow should have been chosen for benediction together with, or as substitutes for, palm, and that an exorcising power should have been ascribed to them. The consecrated palms were used to heal disease, ward off devils, protect the houses where they were brought in against lightning and fire, and the fields where they were planted against hail and storms. But healing power had been ascribed to the palm since earliest times. Egyptian paintings of the 3rd century show the palm had from time immemorial been credited by the Teutonic peoples with the possession of protective qualities. It was natural that olive and willow should have been chosen for the Palm Sunday ceremony, for they are the earliest trees to bud in the spring, their procession, however, may be explained by the intention to Christianize a pagan belief, and it is easy to see how their mystic virtues came in this way to be ascribed to the palm also. When and where the custom first arose is unknown.

Of the reformed churches of England alone Palm Sunday is in the Holy Week celebrations. The blessing of the palms and the procession were, however, abolished at the Reformation, and the name “Palm Sunday,” though it survives in popular usage, is not mentioned in the Book of Common Prayer. The intention of the compilers of the Prayer-book seems to have been to restore the “Sunday next before Easter,” as it is styled, to its earlier Western character of Passion Sunday, the second lesson at matins (Matt. xxvi. 5) and the special collect, Epistle (Phil. ii. 5) and Gospel (Matt. xxvii. 1) at the celebration of Holy Communion all dwelling on the humiliation and passion of Christ, with no reference to the triumphal entry into Jerusalem. The modern revival, in certain churches of an “advanced” type, of the ceremonies of blessing the palms and carrying them in procession has no official warrant, and is therefore without any significance as illustrating the authoritative point of view of the Church of England.

Of the Lutheran churches only that of Brandenburg seems to have kept the Palm Sunday procession for a while. This was prescribed by the Church order (Kirchenordenung) of 1540, but without the ceremonial of blessing the palms; it was abolished by the revised Church order of 1572.

PALMYRA, the Greek and Latin name of a famous city of the East, now a mere collection of Arab hovels, but still an object of interest on account of its wonderful ruins. In 2 Chron.

1 For curious instances of the part played by the ass in medieval church festivals see the article FOOLS, FEAST OF.
one by the Red Sea, Egypt and Alexandria, the other from the Persian Gulf through the Syro-Arabian desert. The latter, when the Nabataean kingdom of Petra (q.v.) came to an end (A.D. 105), passed into the hands of the Palmyrene merchants. Their caravans (σαμαία) travelled right across the desert to the great entrepôt on the Euphrates, Vologesias, about 55 m. south-east of Babylon, or Forath or Charax close to the Persian Gulf (NSI. Nos. 113-171). The trade was enormously profitable, not only to the merchants but to the town, which levied a rigorous duty on all exports and imports; at the same time formidable risks had to be faced both from the desert-tribes and from the Parthians, and successfully to plan or convey a great caravan came to be looked upon as a distinguished service to the state, often recognized by public monuments erected by “council and people” or by the merchants interested in the venture. These monuments, a conspicuous feature of Palmyrene architecture, took the form of statues placed on brackets projecting from the upper part of the pillars which lined the principal thoroughfares. Thus arose, beside minor streets, the imposing central avenue which, starting from a triumphal arch near the great temple of the Sun, formed the main axis of the city from south-east to north-west for a length of 1240 yards, and at one time consisted of not less than 750 columns of rosy-white limestone, each 32 ft. high.

Local industries that seem to have been important. One of the chief of them was the production of salt from the deposits of the desert; another was no doubt the manufacture of leather; the inscriptions mention also a powerful guild of workers in gold and silver (NSI. No. 126); but Palmyra was not an industrial town, and the exacting fiscal system which drew profit even out of the bare necessities of life—such as water, oil, wheat, salt, wine, straw, wool, skins (see Tarif ii. b, NSI. pp. 315 sqq.)—must have weighed heavily upon the artisan class. The prominent townsmen were engaged in the organization and even the personal conduct of caravans, the discharge of public offices such as those of strægos, secretary, guardian of the wells, president of the banquets of Bel, chief of the market (see NSI. Nos. 114, 115, 121, 122), sometimes the victualling of a Roman expedition. The capable performance of these functions, which often involved considerable pecuniary sacrifices, ensured public esteem, honorary inscriptions and statues; and to these honours the head of a great house was careful to add the glory of a splendid tomb, consecrated as the long "sortes" of eternity; cf. Eccles. xii. 5) of himself, his sons and his sons' sons' sons, "which, when a man passes outside the city and overlooks it from the surrounding hillocks, a feature characteristically Arabic, remain the most interesting monuments of Palmyra. Some are lofty towers containing sepulchral chambers in stories; others are house-like buildings with a single chamber and a richly ornamented portico; the sides of these chambers within are adorned with the names and sculptured portraits of the dead. As a rule the buildings of Palmyra do not possess any architectural individuality, but these tombs are an exception. The style of all the ruins is late classic and highly ornate, but without refinement.

The rise of Palmyra to a position of political importance may be dated from the time when the Romans established themselves on the Syrian coast. As early as the first imperial period the city must have admitted the suzerainty of Rome, for decrees respecting its custom-dues were issued by Germanicus (A.D. 17-19) and Cn. Domitius Corbulus (A.D. 57-60). At the same time the city had by no means surrendered its independence, for even in the days of Vespasian (A.D. 69-79) the distinctive name of "the Church of Palmyra" is still preserved, and in the time of Hadrian (A.D. 117-138) it remained an independant and prosperous city with a large population, even though the greater part of the desert still lay a barrier to it. The city was already at this time a dirge centre for commerce and industry, and at the same time it was an important oasis, with the result that the Romans soon found the city to be a dangerous rival to their own possessions in the East (see 2 Macc. viii. 4, and in the native inscriptions, it is called Tadmor, and this is the name by which it is known among the Arabs at the present day (Tadmur, Tadmur). The site of Palmyra lies 150 m. N.E. of Damascus and five days' camel journey from Palmyra, in the oasis of the Syrian desert, 1,300 ft. above sea-level. At this point the great trade routes met in ancient times, the one crossing from the Phoenician ports to the Persian Gulf, the other coming up from Petra and south Arabia.

The earliest mention of Palmyra is in 2 Chron. viii. 4, where Solomon is said to have built "Tadmor in the wilderness"; 1 Kings ix. 18, however, from which the Chronicler derived his statement, reads "Tamar" in the Hebrew text, with "Tadmor" in the Hebrew margin; there can be no doubt that the text is right and refers to Tamar in the land of Judah (Ezek. xlvii. 19; xlviii. 28). The Chronicler, we must suppose, altered the name because Tadmor was a city more familiar and renowned in his day, or possibly because he wished to increase the extent of Solomon's kingdom. The date of the Chronicler may be placed about 300 B.C., so Palmyra must have been in existence long before then. There is reason to believe that before the 6th century B.C. the caravans reached Damascus without coming near the oasis of Tadmor; probably, therefore, we may connect the origin of the city with the gradual forward movement of the nomad Arabs, which finally, on the over-run of the west by the Sassanians, transformed the Babylonian Empire (6th century B.C.). The Arabian tribes began to take possession of the partly cultivated lands east of Canaan, became masters of the Eastern trade, gradually acquired settled habitations, and learned to speak and write in Aramaic, the language which was most widely current throughout the region west of the Euphrates in the time of the Persian Empire (6th-4th century B.C.). It is not till much later that Palmyra first appears in Western literature. We learn from Appian (Bell. civ. v. 9) that in 42-41 B.C. the city was rich enough to excite the cupidity of M. Antonius (Mark Antony), while the population was not too large to save itself by timely flight. The series of native inscriptions, written in Aramaic, begins a few years after; the earliest bears the date 340 of the Seleucid era, i.e. 9 B.C. (Cook, North-Semitic Inscriptions No. 141 = Vogüé, Syrie Centrale No. 30a); by this time Palmyra had become an important trade-post between the Roman and the Parthian states. Its characteristic civilization grew out of a mixture of various elements, Arabic, Aramaic, Greek and Roman. The bulk of the population was of Arab race, and though Aramaic was the dominant language, in common use among the Arab population had by no means disappeared. The proper names and the names of deities, while partly Aramaic, are also in part unmistakably Arabic; it is suggestive that a purely Arabic term (fahā, NSI. No. 136) was used for the septs into which the citizens were divided.

Originally an Arab settlement, the oasis was transformed in the course of time from a mere halting-place for caravans to a city of the first rank. The true Arab despises agriculture; but the pursuit of commerce, the organization and conduct of trading caravans, cannot be carried on without widespread connexions of blood and hospitality between the merchant and the leading sheiks on the route. An Arabian merchant city is thus necessarily aristocratic, and its chiefs can hardly be other than pure Arabs of good blood. Palmyra also possessed the character of a religious centre, with the worship of the Sun-god dominating that of inferior deities.

The chief luxuries of the ancient world, silks, jewels, pearls, perfumes, incense and the like, were drawn from India, China and southern Arabia. Pliny (H. N. xii. 41) reckons the yearly import of these commodities into Rome at not less than three-quarters of a million of English money. The trade followed two routes: 1 How the name Palmyra arose is obscure. The Greek for a palm-tree, ψάμων (of the Greek ending -saων) could not have been affixed to the Latin palma. Schultens (Vita Sal., Index geogr.) cites Talmur as a variant of the Arabic name; this might mean "abounding in palms" (from the root tamar); otherwise Tadmor may have been originally an Assyrian name. See Lagarde, Bildung der Nomina, p. 125 n.

1 One of these tomb-towers, called Kasr eth-Thuniyeh, is 111 ft. high, 33£ ft. square at the base, 25 ft. 8 in. square above the basement; it contains six stories and places for 480 bodies. Opposite the entrance within is a hall with recesses for coffins and a richly panelled ceiling; underneath is an immense vault.
position of Palmyra as an intermediate state between the two great powers of Rome and Parthia was recognized and carefully watched. The splendid period of Palmyra (A.D. 130-270), to which the greater part of the inscribed monuments belong, started from the overthrow of Petra (A.D. 105), which left Palmyra without a competitor for the Eastern trade. Hadrian treated the city with special favour, and on the occasion of his visit in A.D. 130, granted it the name of Hadriana Palmyra (NSI. p. 322). Under the same emperor the customs were revised and a new tariff promulgated (April, A.D. 137), cancelling the loose system of taxation "by custom" which formerly had prevailed. The great fiscal inscription, which still remains where it was set up, gives the fullest picture of the life and commerce of the city. The government was vested in the council (boule) and people (epimeleis), and administered by civil officers with Greek titles, the proedros (president), the grammateus (secretary), the archons, syndics and dekadroni (a fiscal council of ten), following the model of a Greek municipality under the Roman Empire. At a later date, probably under Septimius Severus or Caracalla (beginning of 3rd century), Palmyra received the Jus italicum and the status of a colony; the executive officials of the council and people were called strategoi, equivalent to the Roman duumviri (NSI. Nos. 121, 127); and when Odenathus became Roman citizens began to take Roman names, usually Septimius or Julius Aurelius, in addition to their native names.

It was the Parthian wars of the 3rd century which brought Palmyra to the front, and for a brief period raised her to an almost dazzling position as mistress of the Roman East. A new ambition of ambition was opened to her citizens in the Roman honours that rewarded services to the imperial armies during their frequent expeditions in the East. One house which was thus distinguished had risen to a leading place in the city and before long played no small part in the world's history. Its members, as we learn from the inscriptions, prefixed to their Semitic names the Roman gentilicium of Septimius, which shows that they received the citizenship under Septimius Severus (A.D. 193-211), presumably in recognition of their services in connexion with his Parthian expedition. In the next generation Septimius Odaenath or Odenathus, son of Hairan, had attained the rank of Roman senator (συγκρατης, Vogt No. 21, NSI. p. 285 n.), conferred no doubt when Alexander Severus visited Palmyra (a.d. 231); he died a.d. 231; and again, Septimius Hairan, seems to have been the father of the family to receive the Rās Tadmor ("chief of Tadmor") in addition to his Roman rank (NSI. No. 125); while his son—the relationship, though nowhere stated, is practically certain—the famous Septimius Odaenath, commonly known as Odenathus (q.v.), the husband of Zenobia, received even higher rank, the consular dignity (ἐπιτάγμα) which is given him in an inscription dated a.d. 258, in the reign of Valerian (NSI. No. 126). The East was then agitated by the advance of the Parthian Empire under the Sassanidae, and the Palmyrenes, in spite of their Roman honours and their Roman civilization, which did not really go much below the surface, were by no means prepared to commit themselves altogether to the Roman side. But Parthian ambitions made it necessary for the Palmyrenes to choose one side or other, and their choice leaned towards Rome, both because they dreaded interference with their religious freedom and because the Roman emperor was further off than the Parthian king. In the contests which followed there can be no doubt that the Palmyrene princes cherished the idea of an independent empire of their own, although at first Odenathus showed adherence to the Roman suzerainty until the closing act of the drama. Their opportunity came with the disaster which befell the Roman army under Valerian (q.v.) at Edessa, a disaster, says Mommsen, which had nearly the same significance for the Roman East as the victory of the Goths at the mouth of the Danube and the fall of Decius; the emperor was captured (a.d. 260) and died in captivity. The Persians swept victorious over Asia Minor and North Syria; but not without resistance on the part of Odenathus, who inflicted considerable losses on the bands returning home from the pillage of Antioch. It was probably not long after this that Odenathus, with a keen eye for his advantage, made an attempt to attach himself to Shapur I. (q.v.) the Persian king; his gifts and letters, however, were contemptuously rejected, and from that time, as it seems, he threw himself warmly into the Roman cause. After the captivity and death of Valerian, Gallienus succeeded to a merely nominal rule in the East, and was too careless and self-indulgent to take any active measures to recover the lost provinces. Thereupon the two leading generals of the Roman army, Macrianus and Callistus, renounced their allegiance and proclaimed the two sons of the former as emperors (A.D. 261). During the crisis Odenathus remained loyal to Gallienus, and was rewarded for his fidelity by the grant of a position without parallel under ordinary circumstances; as hereditary prince of Palmyra he was appointed dux Orientis, a sort of vice-emperor for the East (A.D. 262). He started promptly upon the work of reforming the Palmyrene troops, strengthened by what was left of the Roman army. But his offensive against Shapur, defeated him at Ctesiphon, and in a series of brilliant engagements won back the East for Rome. During his absence at the wars, we learn from the inscriptions (A.D. 262-267) that Palmyra was administered by his deputy Septimius Worod, "procurator ducenarius of Caesar our lord," also styled "commandant," as being Odenathus' viceroys (ἀρχηγὸς, NSI. Nos. 127-129), Then in the zenith of his success Odenathus was assassinated at Ḫomṣ (Emessa) along with his eldest son Herodes (A.D. 266-267). The fortunes of Palmyra now passed into the vigorous hands of Zenobia (q.v.), who had been actively supporting her husband in his policy. Zenobia seems to have ruled on behalf of her young son Wahab-allath or Atenodorus as the name is Graecized, who counts the years of his reign from the date of his father's death. Under Odenathus Palmyra had extended her sway over Syria and Arabia, perhaps also over Armenia, Cilicia and Cappadocia; but now the troops of Zenobia, numbering it is said 70,000, proceeded to occupy Egypt; the Romans under Probus resisted vigorously but were defeated by the beginning of A.D. 270, when Aurelian succeeded Claudius; and after the death of Wahab-allath was governing Egypt with the title of "king." His coins of 270 struck at Alexandria bear the legend v(ir) c(onsularis) R(omanorum) i(mperator) d(ux) R(omanorum) and display his head beside that of Aurelian, but the latter alone is styled Augustus. Meanwhile the Palmyrenes were pushing their influence not only in Egypt but in Asia Minor; they contrived to establish garrisons as far west as Ancyrë and even Chaldæan opposite Byzantium, while still professing to act under the terms of the joint rule conferred by Gallienus. Then in the course of the year A.D. 270-271 came the inevitable and open breach. In Palmyra Zenobia is still called "queen" (βασίλεισσα, NSI. No. 131; cf. Wadd. 2628), but in distant quarters, such as Egypt, she and her son claim the dignity of Augustus; 

1 The full text, both Greek and Palmyrene, with an English translation, is given in NSI. pp. 323-340. The tariff should be compared with the Greek Tariff of Coptos A.D. 90 (Flinders Petrie, Kryptos, pp. 27 sqq.) and the Latin Tariff of Zaraï (Corp. inscr. lat. vili. 4508).

2 Petrus Patricius, Fragmenta graeca, iv. 187.

3 The Palmyrene archers were especially famous. Appian mentions them in connexion with M. Antony's raid in A.D. B.C. (Bell. civ. v. 9). Later on a contingent served with the Roman army in Africa, Britain, Italy, Hungary, where stone-stones with Palmyrene and Latin inscriptions have been found; see Lidzbarski, Nordc. 1896, pp. 268 sqq.; E. R. Goodchild, "A Latin inscription of the time of Marcus Aurelius," and NSI. p. 32, on a fragment now in the Free Library of the town, was found in the neighbouring Roman camp; it is given in NSI. p. 250. The Palmyrene soldiers who met it was no doubt an archer. Jewish tradition had reason to remember these formidable Palmyrenes in the Roman army; according to the Talmud 80,000 of them assisted at the destruction of the first temple, 8000 at that of the second! Talm. Jerus. Ta'amith, fol. 68 a, M. Zad. Eika, ii. 2. For other references to Palmyra (called Tarmod) in the Talmud see Neubauer Geogr. du Talm. 301 sqq.
Palmyra was a dialect of western Aramaic, and belongs to the same group as Nabataean and the Aramaic spoken in Egypt. In some important points, however, the dialect is related to the eastern Aramaic or Syrian (e.g. the plur. ending in 'e'; the dropping of the final i of the pronominal suffix third pers. sing., with nouns, and of the final a of the third pers. pl. of the verb; the infin. ending $d$. &c.). But the relation to western Aramaic is closer; especially characteristic are the following features: the suffixes of the plural are nie, nes, which are found in eastern dialects with n or l; the plur. ending -ayyeh; the forms of the demonstrative pronouns, &c. As the bulk of the population was of Arab race, it is not surprising that many of the proper names are Arabic. The names and the names of the gods also show a marked resemblance to the names of the gods and goddesses of the neighboring Arab tribes.

The technical terms of municipal government are mostly Greek, transliterated into Palmyrene; a few Latin words occur, of course, in Aramaic forms. For further characteristics of the dialect see Nödeke, ZDMG. xxix. 85-100.

The writing is a modified form of the Old Aramaic character, and especially interesting because it represents almost the last stage through which the ancient alphabet passed before it developed into the Hebrew square character.

The names of the months were the same as those used by the Nabataeans, Syrians, and later Jews, viz. the Babylonian. The calendar was the Syro-Macedonian, or from the primitive lunar, calendar, which Roman influence disseminated throughout Syria; it was practically the same as the Syro-Macedonian calendar used in the Seleucid era, which began in October 312 B.C.

Religion. — The religion of Palmyra did not differ in essentials from that of the north Syrians and the Arab tribes of the eastern desert. The chief god of this religion was a solar deity, called Samas or Shamash ("sun"), or Bel, or Malak-bel, whose great temple is still the most imposing feature among the ruins of Palmyra. Both Bel and Malak-bel were the symbols of the city of Palmyra. Sometimes the chief deity was identified with the sun-god, which was called "Palmyra, the moon-god who is represented as a young Roman warrior with a large crescent attached to his shoulders (Rom. 1. and Vogüé p. xii. No. 141). The great goddess of the Arameans, Athar-anath, in Greek Atargatis.

Transcribed Malak-bel, Malak-bel, &c., in the Palm. inscr. given in N.S.I. p. 268, translated Sol sanctissimus; it was furthermore applied to the sun-god with Zeus. Malak-bel has been explained as "messenger of Bel"; but more probably Malak is the common Babylonian epithet maltik given to various gods, and means "counselor"; Malak-bel will then be the sun as the visible representative of Bel.

Nabataeans, Zeus, Artemis, and the Syrian goddess, the chief goddess of the old Arab tribes, were also worshipped at Palmyra. Another deity whose name occurs in votive inscriptions, is Baal-shamin, i.e. "B of the heavens." — Zebos kryptos, sometimes called "lord of eternity," but he was not identical with the chief deity of the Palaestinae, which he must have been, though he probably had a temple there. Another interesting divine name, lately discovered, is that of a distinctly Arabic deity "She-almuq the good and bountiful god who does not drink wine (I. 40; II. 46) that he came from the place now called Palmyra, and was the protector of the people. — The divine patron of the caravan. A common formula in Palmyrian dedications runs "To him whose name is blessed for ever, the god and the compassionate" out of reverence for the god who protects the caravan. Malak-bel is the chief deity of Palmyra, and it is worth noticing that this epithet like "lord of eternity" (or, "of the world"), has a distinctly Jewish character. Altogether about 22 names of gods are found in Palmyre; some of them, however, only occur once.

After its overthrow by Aurelianus, Palmyra was partially revived as a military station by Diocletian (end of 3rd century A.D.), as we learn from a Latin inscription found on the site. Before this he had a religious cultus of a goddess named Zenobia, of whom the fathers present at the Council of Nicea (a.d. 325) was Marinus bishop of Palmyra. The names of two other bishops of the 5th and 6th centuries have come down to us. About a.d. 400, Palmyra was the station of the first Illyrian legion (Not. digg. i. 85, ed. Stocke) captured by the British in 272, and the reconquest of the city is marked by the wall on which the ruins still remain (Procopius, De aedif. ii. 11.). At the Moslem conquest of Syria, Palmyra capitulated to Khalid (see CALIFATE) without embracing Islam (Baladur; Baladur, i. 11). TheBluetooth, II. 842), and was recovered by the city destroyed by Ibb an Athir, A.D. 127, ed. Tornberg, V., 249; cf. Pto. hist. or. 139, Ibn Wadj. ii. 230. In this connexion Yaqut tells a curious story of the opening of one of the tombs by the name of Zenobia. In spite of numerous incidents, relating the legend of Roderic the Goth, shows some traces of local knowledge. The ruins of Palmyra greatly interested the Arabs, and are commemorated in several poems quoted by Yaqut and others; they are referred to many times in the popular narratives of the Arab, and there are several editions of the city of Palmyra, Ibn an Athir, A.D. 120, ed. Tornberg, V., 249; cf. Pto. hist. or. 139, Ibn Wadj. ii. 230. All that has been collected by Quemereum, Sulans Mamlouks, ii. 1. p. 255 sqq. All but annihilated by an earthquake in the 11th century, it recovered considerable prosperity; when Benjamin of Tudela visited the city, which was still called Tadmor, he found 2000 Jews within the walls (12th century). It was still a wealthy place as late as the 14th century; but in the general decline of the East, and owing to changes in the trade routes, it sank at length to a poor group of hovels gathered around the great temple, and to the few old monasteries and churches now known to Europe through the visit of Dr William Halilfix of Aleppo in 1691; his Relation of a voyage to Tadmur has been printed from his autograph in the Pal. Explor. Fund's Quarterly Statement for 1890. A few inscriptions and MSS. have been collected by the B. Waddington (vol. iii.) and De Vogüé (La syrène centrale) made in 1861-1862. Since that time the most valuable document which has come to light is the great royal inscription discovered in 1882 by Prof. Schumacher, and published by the British Museum (see Palmyra).

Mordtmann Palmierische (1889); Clermont-Ganneau, Études de philologie et d'histoire de l'Antiquité (1893); Recueil d'études, i. and ii.; Soberheim, Palm. Inschr. (1905). The Répertoire d'épigr. sém. contains the new words which have been published since 1900. For the coins of Volos' Ferraris von Palmyra (1866) must be read with his later essay in the Num. Zeit. cxxii. (1870). Critical discussions of the history will be found in Schiller, Gesch. d. Römischen Kaiserzeit, i. 2 Teil (1883), pp. 823 sqq. and 857 sqq., and Mommsen, Provinces of the Roman Empire, (Eng. trans., 1886), pp. 92 sqq.

Palmyra, a range of hills in south India, in the Madura district of Madras. They are an offshoot from the western Ghats, and, while distinct from the adjacent Anamalai hills, form part of the same system. They contain the hill station of Kodakkanal (7400 ft.), which has a milder and more equable climate than Ootacamund in the Nilgiri hills. There is some coffee cultivation on the lower slope.

Palna Alto, the city of Santa Clara county, California, U.S.A., between two of the coast ranges, about 25 m. S. of San Francisco.
and about 18 m. from the sea. Pop. (1910) 4456. It is served by the coast division of the Southern Pacific railway, and is the railway junction for Leland Stanford Jr. University (q.v.), which is about 1 m. south-west of the city. At Menlo Park is St Patrick's Theological Seminary (Roman Catholic). By all real estate deeds the sale of intoxicating liquors is for ever prohibited in the city; and an act of the state legislature in 1909 prohibited the sale of intoxicating liquor within 1½ m. of the grounds of the university. The name (Sp. "tall tree") was derived from a solitary redwood-tree standing in the outskirts of the city. Palo Alto was laid out in 1804, but had no real existence before 1806. It was incorporated as a town in 1849, having previously been a part of Mayfield township; in 1909 it was chartered as a city. Palo Alto suffered severely in the earthquake of 1906.

PALOMINO DE CASTRO Y VELASCO, ACISCLO ANTONIO (1653-1726), Spanish painter and writer on art, was born of good family at Bujalance, near Cordova, in 1653, and studied philosophy, theology and law at that capital; received also lessons in painting from Valdes Leal, who visited Cordoba in 1672, and afterwards from Alfaro (1675). After taking minor orders he removed to Madrid in 1678, where he associated with Alfaro, Coello and Careño, and executed some indifferent frescoes. He soon afterwards married a lady of rank, and, having been appointed alcalde of the mesta, was himself ennobled; and in 1688 he was appointed painter to the king. He visited Valencia in 1697, and remained there three or four years, again devoting himself with but poor success to fresco painting. Between 1705 and 1715 he resided for considerable periods at Salamanca, Granada and Cordoba; in the latter year the first volume of his work on art appeared in Madrid. After the death of his wife in 1725 Palomino took priest's orders. He died on the 13th of August 1726.

His work in 3 vols. folio (1715-1724), entitled El Museo pictorico y escultorico, consists of three parts, of which the first two, on the theory and practice of the art of painting, are without interest or value; the third, with the subtitle El Parnaso español pintoresco luviano, is a mine of important biographical matter relating to Spanish artists, which, notwithstanding its faulty style, has procured for the author the not altogether undeserved honour of being called the "Spanish Vasari." It was partially translated into English in 1792; an abridgment of the original (Las Vidas de los pintores y esculptores españoles) was published in London in 1742, and afterwards appeared in a French translation in 1749. A German version was published at Dresden in 1761, and a reprint of the entire work at Madrid in 1797.

PALSTOCK, ROBERT (1697-1767), English writer, the only son of Thomas Palstocket of St James's, Westminster, was born in 1697. He was an attorney and lived for some time in Clement's Inn, whence he removed before 1750, to Bristol. Lambeth. He married Anna Skinner, through whom his son, also named Robert, inherited a small property at Ryme Intrinsica, Dorset. There Robert Palstock, who died in London on the 20th of March 1767, was buried. Palstock owes his fame to his romantic Life and Adventures of Peter Wilkins (1751), which excited the admiration of men like Coleridge, Southey, Charles Lamb, Sir Walter Scott and Leigh Hunt. It has been several times reprinted, notably with an introduction by Mr A. H. Bullen in 1884. It was translated into French (1765) and into German (1767).

PALUDAN-MÜLLER, FREDRIK (1809-1876), Danish poet, was the son of Jens Paludan-Müller, from 1830 to 1836 bishop of Aarhus, and born at Kjertemunde in Fünen, on the 7th of February 1809. In 1819 his father was transferred to Odense, and Frederik was sent to Copenhagen. In 1825 he passed to the university of Copenhagen. In 1832 he opened his poetical career with Four Romances, and a romantic comedy entitled Kjørlighed ved koblet ("Love at Court"). This enjoyed a considerable success, and was succeeded in 1833 by Danserindren ("The Dancing Girl"). Paludan-Müller was accepted by criticism without a struggle, and few writers have excited less hostility than he. He was not, however, well inspired in his lyrical drama of Amor and Psyche in 1834 nor in his Oriental tale of Zuleimas flugt ("Zuleima's Flight") in 1835, in each of which he was too vividly influenced by Byron. But he regained all that he had lost by his two volumes of poems in 1836 and 1838. From 1838 to 1840 Paludan-Müller was making the grand tour in Europe and his genius greatly expanded; in Italy he wrote Venus, a lyrical poem of extreme beauty. In the same year, 1841, he began to publish a great work on which he had long been engaged, and which he did not conclude until 1848; this was Adam Homo, a narrative epic, satirical, modern and descriptive, into which Paludan-Müller wove all his variegated impressions of Denmark and of love. This remains the typical classic of Danish poetical literature. In 1844 he composed three enchanting idyls, Dryadens bryllup ("The Dryad's Wedding") Titthom ("Titthonus") and Abels død ("The Death of Abel"). From 1850 a certain decline in the poet's physical energy became manifest and he wrote less. His majestic drama of Kalanan belongs to 1854. Then for seven years he kept silence. Paradiset ("Paradise") 1861; and Benedikt fra Nirvica ("Benedict of Nirvica") 1861; bear evidence of malady, both physical and mental. Paludan-Müller wrote considerably after this new recovered his early raptures, except in the very latest of all his poems, the enchanting welcome to death, entitled Adonis. The poet lived a very retired life, first in Copenhagen, then for many years in a cottage on the outskirts of the royal park of Fredensborg, and finally in a house in Ny Adelsgade, Copenhagen, where he died on the 27th of December 1876.

PAMIRS, a mountainous region of central Asia, lying on the north-west border of India. Since 1875 the Pamirs have probably been the best explored region in High Asia. Not only have many travellers of many nationalities directed their steps towards the Bam-i-dunya ("the Roof of the World") in search of native culture or of scientific information, but the government surveys of Russia and India have met in these high altitudes, and there effected a connexion which will help to solve many of the geodetic problems which beset the superficial survey of Asia. Since Wood first discovered a source of the Oxus in Lake Victoria in 1837, and left us a somewhat erroneous conception of the physiography of the Pamirs, the gradual approach of Russia from the north stimulated the processes of exploration from the side of India. Native explorers from India first began to be
busy in the Pamirs about 1860, and continued their investigations for the following fifteen years. In 1874, the mission of Sir D. Forsyth to Yarkand led to the first systematic geographical exploitation of the Pamir country. In 1883, Ney Elias made his famous journey across the Pamirs from east to west, identifying the Rang Kul as the Dragon Lake of Chinese geographers—a distinction which has also been claimed by some geographers for Lake Victoria. Then Lockhart and Woodthorpe in 1886 passed along the Wakhan tributary of the Oxus from its head to Ishkashim in Badakhshan, and completed an enduring record of most excellent geographical research. Bonvillot in 1887, Littledale in 1888, Cumberland, Bower and Dauvergne, followed by Younghusband in succeeding years, extending to 1890; Dummore in 1892 and Sven Hedin in 1894–1895, have all contributed more or less to Pamir geography; but the honours of successful inquiry in those high altitudes still fall to Lord Curzon, whose researches in 1894 led to a singularly clear and comprehensive description of Pamir geography, as well as to the best map compilation that till then had existed. Meanwhile Russian explorers and Russian topographers had been equally busy from the north. The famous soldier Skobelev was probably the first European to visit the Great Kara Kul. He was followed by scientific missions systematically organized by the Russian government. In 1883 Putila's mission started south. Grimbekwsky was hard at work from 1888 to 1892. Yanov began again in 1891, after a short spell of rest, and has left his mark as a permanent record in the valley of Sarhad (or Wakhan), between the Baroghil pass and Bozai Gumbaz. Finally, in 1895, the Russian mission under General Schelkovsky met the British mission under General Gerard on the banks of Lake Victoria, and from that point to the Chinese frontier eastward demarcated the line which thereafter was to divide Russian from British interests in highest Asia. Since then other travellers have visited the Pamirs, but the junction of the Russian and British surveys (the latter based on triangulation carried across the Hindu Kush from India) disposes of any further claim to the honours of geographical exploration.

Our estimate of the extent of Pamir conformation depends much on the significance of the word Pamir. If we accept the Persian derivation of the term (which is advanced by Curzon as being perhaps the most plausible), *pa-i-mir*, or "the foot of mountain peaks," we have a definition which is by no means an inapt illustration of the actual facts of configuration. It has been too often assumed that the plateau of Tibet and the uplands of the Pamirs are analogous in physiography, and that they merge into each other. This is hardly the case. Littledale points out ([*R. G. S. Journ.* vol. VII]) that the high-level valleys of glacial formation which distinguish the Pamirs have no real counterpart in the Chang or plains of Tibet. The latter are 2000 ft. higher; they are intersected by narrow ranges, and are drained by no rivers of importance. They form a region of salt lakes and stagnant marshes, relieved by wide flat spaces of open plateau country. The absence of any vegetation beyond grass or scrub is a striking feature common to both Pamir and Chang, but the resemblance ceases, and the physical conformation of mountain and valley to the east and to the west of the upper sources of the Zarafshan is radically distinct.

The axis, or backbone, of Pamir formation is the great meridional mountain chain of Sarikol—the ancient Taurus of tradition and history—which stands the highest peak north of the Himalaya, the Muztagh Ata (25,800 ft.). This great chain of the upper sources of the Oxus on the west from the streams which sweep downwards into the Turkestan depression of Kashgar on the east. There are the true Pamirs (i.e. valleys reaching up in long slopes to the foot of mountain peaks) on either side, and the Pamirs on the west differ in some essential respects from those on the east. On the west the following are generally recognized as distinct Pamirs: (1) the Great Pamir, of which the dominant feature is Lake Victoria; (2) the Little Pamir, separated from the Great Pamir on the north by what is now known as the Nicholas range; (3) the Pamir-i-Wakhan, which is the narrow trough of the Wakhan tributary of the Oxus, the term Pamir applying to its upper reaches only; (4) the Alichur—the Pamir of the Yeshil Kul and Ghund—immediately to the north of the Great Pamir; (5) the Sarez Pamir, which forms the valley of the Murghab river, which has here found its way round the east of the Great Pamir and the Alichur from the Little Pamir, and now makes westwards for the Oxus. This branch was considered by many geographers as the main Oxus stream, and Lake Murgab, at its head, was by them regarded as the Oxus source. At the foot of the Sarez Pamir stands the most advanced Russian outpost of Murgab. To the north-east of the Alichur are the Rang Kul and the Kanu Kul (or Kargosh) Pamirs. Rang Kul Lake occupies a central basin or depression; but the Kanu Kul drains away north-eastwards through the Sarikol (as the latter, bending westwards, merges into the Trans-Alai) to Kashgar and the Tarim, the head of the Turkestan valley of Afghanistan distinguish all these Pamirs. They are hemmed in and separated by snow-capped mountain peaks and ridges, which are surrounded by glaciers terminating in moraines and s hingle slopes at the base of the foothills. Long sweeps of grassy upland breastoned with boulders lead from the stream beds up to the snowfields, yellow, grey or vivid green, according to the season and the measure of sunlight, fold upon fold in interminable succession, their bleak monotony being only relieved by the grace of flowers for a short space during the summer months.

To the east of the Sarikol chain is the Taghdumbash Pamir, which claims many of the characteristics of the western Pamirs at its upper or western extremity, where the Karakurak, which drains it, is a comparatively small stream. But where the Karakurak, joining forces with the Kunjerab, stretches out northwards for a comparatively straight run to Tashkurgan, dividing amongst the parallel ranges of Sarikol and Kandar, which together form the Sarikol chain, the appellation Pamir can hardly be maintained. This is the richest portion of the Sarikol province. Here are stone-built houses collected in scattered detachments, with a spread of cultivation reaching down to the river. Here are water-mills and many permanent appliances of civilization suited to the lower altitude (11,500 ft.), the average height of the upper Pamirs being about 13,000, and here we are no longer near the sources of the river at the foot of the mountain peaks. One other so-called Pamir exists to the east of Sarikol, separated therefrom by the eastern range (the Kandar) of the Sarikol, which is known as Mariam or Marion. But this Pamir is situated nowhere near the sources of the Zarafshan or Raskam river, which it borders, and possesses little in common with the Pamirs of the west. The Mariam Pamir defines the western extremity of the Kuen Lun, which stretches eastwards for 250 m. before it becomes the political boundary of northern Tibet.

The Muztagh chain, which holds within its grasp the mightiest system of glaciers in the world, forms a junction with the Sarikol at the head of the Taghdumbash, where also another great system (sou of the Hindu Kush) has its eastern roots. The political boundaries of Afghanistan and the northern reaches of the Pamirs mark a point in about 70° E., where it is transferred to the watershed of the Kuen Lun. Within the limits of these partially explored highlands, lying between the Pamirs and the Tibetan table-land, exact geographical definition is impossible. But we may follow Godwin-Austen in accepting the main chain of the Muztagh as merging into the central mountain system of the Tibetan Chang, its axis being defined and divided by the transverse stream of the Shyok, which rising in the desert of the Shahsavan, in which the Shyok rises, is a subsidiary northern branch. The pass over the Karakoram (18,500 ft.) is the most formidable obstacle on the main trade route between Lep and Kashgar.
and opens a difficult and dangerous route to Gilgit. The Tagh-
dumbash is claimed by China and Kanjut (or Hunza), and there is
consequently an open boundary question at this corner of the Pamirs.

From Lake Victoria of the Great Pamir the northern boundary of
that extended strip of Afghan territory which is known to be
Kush is to be traced: westwards, in the Lake Victoria
affluent of the Oxus; and eastwards, on the Nicola
range, dividing the Great and Little Pamirs, till it over-
dross of the (OldMurghab) river basin at 74° 49' E. Here it diverges southwards to the Sarikol
chain, north of Tagh dumbash. This eastward extension was
drawn down by the Pamir Boundary Commission of 1895. All the head of
the Oxus and Murghab are Afghan territory, but no military posts have been established so far. The
Alchyr, Rang Kul, Kargosh (Kara Kul) and Sarez are Russian
Pamirs.

The Maroum Pamir is Chinese.

The Wakhan Valley (Wakhjir) is the Wakjhir water-part, Lake
Chukhtamkin near the sources of the Aksu, and Lake Victoria of the
Great Pamir have all been claimed as indicating the
true source of the Oxus. But detailed examination of
the sources of the Khur and its tributaries in the
mountains of the Pamir has led to the conclusion that
the lakes of the Wakhan Valley are only minor sources in the
course of glacial streams (incidents which are diminishing in volume
day by day), rather than original springs or sources. The
same glacial beds of the islands range send down tributary waters to the
Pamir and Wakhan Rivulets, to the Osh, the Aksu, or the
Wakhan, and there is no reason to doubt that the
water-mass of the Wakhjir should be regarded as
the most important contribution to the main stream. There is evidence also that glacial moraines formative
at this time encroached on the uppermost area of these
tributary streams. It would be as rash to assert that from Lake Victoria
no waters could ever have issued with an eastward flow as it would
be to state that from Chukhtamkin none ever flowed westward. But
measure of the variety of these Pamir streams and geographers in the
century of our era must not be balanced on such points as
these.

There is no evidence that the Pamirs were ever the support
of permanent settlements. The few mud-built buildings which once
existed at Chukhtamkin and at Langar only date
recent occupation which could hardly have possessed a
permanent character, and the few shrines and domed
chambers which mark the encroachments of the
empty desertion of the Pamir slopes are all of them of recent
construction. The nomadic population which seeks pasture
among the summer months in these dreary altitudes is entirely
Kirkhi, and it may be regarded as being in part an
aftermath of those which flourished in China in the
Russian period. The non-Russian population during the summer of
1895 could not have amounted to more than a few hundred souls—
occupying a few encampments in the Little Pamir and in the
Tagh-
dumbash region.

The Kirghiz Pamir, with its clear sky, its high-altitude objects,
i.e. the Tashkurgan Pass, the Tagh dumbash and Lake Victoria, is
most magnificent as a whole, and there are indications
amongst the Kirghiz of an old settlement of Turkestan that
of the ancient Turkestan, the Kirghiz and the Pamirs of the Tagh dumbash.

The Kirghiz are Mohammedans by faith, but amongst
them there are curious survivals of an ancient ritual of which
the origin is to be traced to those Nestorian Christian communities of Central Asia which existed in the
middle ages. They are mentioned in Marco Polo's time, and is supposed to have survived
for another century (1570). The last Gurkhan of the
Kara Khitai Empire in the early part of the 13th century
(tradition of the Oldest John) who was mentioned by a Chinese
author, one of the four chief tribal divisions
mentioned by Nia Yi. The Naiman tribe claim kinship with the
Kipchaks. It is curious that the same survival of Christian
ceremonial should be found amongst the Sarikols, a tribe of people of
ancestral Kirghiz origin. It is probable that the
Kirghiz are a mixed race, and that amongst the
Kirghiz, Christian symbols have been discovered
in the southern towns of the Turkestan of Sven Hedin.

The total area of the Pamir country may be estimated as about
150.000.000 acres, which is about one-tenth of the pasture land and the rest mountains. All of it once
formed part of the ancient kingdom of Bolor, itself a
survival of the yet more ancient empire of the Yu-chi, or
Chu. Hence it is probable that regions of this kind
there have been one or two recognized trade routes from east to west through all ages. The most important commercially
was that which passed north-west via Tashkurgan
and Lake Victoria to Badakshan, which was also
north of the Oxus; but the route via Tashkurgan and
Lake Victoria to Badakshan was also well trodden. The
great pilgrim route of Buddhist days was that which connects the
ancient Buddhist cities of the Takla Makan in Chinese Turkestan
and Chitral (Kashmir), by the Baroghil Pass across the
Hindu Kush. This was but one link in a chain of devout peregrination

which stretched from China to India, and which included every
intervening Buddhist centre of note which existed in the early
centuries of our era.

For six or seven months of the year (November to April) the
Pamirs are held under the shadow of the perpetual snows, which
in the passes nearly impracticable. The mean temperature during
the month of January recorded by Russian observers
at the Murghab—Pamirs post is -13°F.

In July the snow lies at 62° E., the elevation of the station being
11,000 ft. During the spring and summer months the prevalence
of fierce cutting winds, which are shaped by the conformation of the
valleys into blasts as through a funnel, following the strike of the
valleys either up or down, makes travelling painful and
impracticable. There is no day that does not see the
summer atmosphere is often bright and exhilarating, but there is a
constant tendency to sudden squalls of wind and rain, which pass
as quickly as they gather. The most settled record of the Pamir
Boundary Commission of 1895 lasted from the 16th of August to the
11th of September, the maximum temperature being recorded
at 77°F. on the 21st of August at Kizil Rabat, (12,570 ft.); and yet on
the 16th of August snow had fallen to the depth of 6 in. in the
Himalayas. The

PAMPA, LA—PAMPAS

PAMPA, LA, a territory of the southern pampa region of
Argentina, bounded N. by Mendoza, San Luis and Cordoba,
E. by Buenos Aires, S. by the territory of Rio Negro, from which it is
separated by the river Colorado, and W. by Mendoza.

The Pampa is a vast tract of savanna, stretching from the
most southern part of the great Argentine pampas, from which its
name is derived, but in reality only a part of its surface belongs
to the plains region. The western and southern part (perhaps the
larger) is much broken by hills, swamps and sandy wastes,
with occasional stretches of wooded country. The western half is
crossed by a broad depression, extending from Mendoza south-
east to an intersection with the valley of the Colorado, which was
once the outlet of the closed drainage basin occupied by the
provinces of Mendoza, San Juan and San Luis. This depression is
partly filled with swamps and lakes, into which flow the
rivers Atuel and Salado. An obscure continuation of these
rivers, called the Chabi-lebou, flows south-east from the great
swamps into the large lake of Urrelaques, about 60 m. north of
the Colorado. There are a great number of lakes in La Pampa,
especially in the south-east. The eastern half is described as
fertile and well adapted for grazing, although the rainfall
is very light. Since the closing years of the 19th century there
has been a large emigration of stock-raisers and agriculturists.
Pampas, and the territory has become an important
producer of cattle and sheep, wheat, Indian corn, linseed, barley
and alfalfa. The climate is excessively dry, and the temperature
ranges from the severe frosts of winter to an extreme of 104°F.
in summer. Strong, constant winds are characteristic of this
region. Railways have been extended into the territory from Buenos Aires and Bahia Blanca, the latter being the nearest
seaport. There is connexion also with the Transandine rail-
way line on the north. The capital is General Acha (pop. about
2000 in 1905), and the only other places of importance are Santa
Rosita de Toay and Victorica, both small, uninteresting "camping
villages.

PAMPAS (Span. La Pampa, from a Quichua word signifying
dian open level space or terrace), an extensive plain of Argentina,
the river Colorado north to the Gran Chaco, and from the
foothills of the Andes east to the Paraná and Atlantic
coast. It consists of a great calcareo-arillaeous sheet, once

1 There are other pampas in South America, such as the Pampas de Aullaquis, in Bolivia, the Pampas del Sacramento between the
Hualaque and Uayali rivers in eastern Peru, and others less well
known, but when the word Pampas is used alone the great Argentine
plain is meant.
PAMPERO—PAMPILHIS

the bed of an ancient sea, covered on the west by sjngle and sand, and on the east by deposits of estuary silt of irregular thickness brought down from the northern highlands. Its western and northern limits, formed by the Morada and Lleres slopes of the Andes, provinces, he three of the great forested depressions of the Gran Chaco, cannot be accurately defined, but its area is estimated at 200,000 to 300,000 sq. m. Its greatest breadth is across the south, between the 36th and 37th parallels, and its least in the north, where the eastern ranges of the Andes project deeply into its north-western angle. Its surface is broken in the north-west by the sierras of Tucuman, Catamarca, San Luis and Cordoba, the latter rising from the midst of the plain, and by some small isolated sierras and hills on the south. It has a gradual slope from north-west to south-east, from an elevation above sea-level of 2320 ft. at Mendoza to 20 ft. at Buenos Aires on the La Plata—the distance across (between Mendoza and Buenos Aires) being about 65 m. There are other slight irregularities in its surface, such as the longitudinal depression on the west, the saline, arid depression west of the Cordoba sierras, the Mar de Chiquita depression N.E. of Cordoba, and some smaller areas elsewhere. Apart from these the plain appears perfectly level. The east, which is humid, fertile and grassy, has no natural break, and is broken in the vicinity of Chaco Chiquita to the north, where algarobas and some of the Chaco species are to be found. In the extreme south some species of low, thorny bushes cover considerable areas in the vicinity of the hill-ranges, otherwise the plain is destitute of native trees. Since the arrival of Europeans several species have been introduced successfully, such as the eucalyptus, poplar, paraiso (Melia Azedarach), peach, willow, ombra (Pircunio) and others.

The distinctive vegetation of the grassy pampas is the tall, coarse-leaved "pampas grass" (Gynernum argenteum) whose feathery spikes often reach a height of eight or nine feet. It covers large areas to the exclusion of all other species except the trefoils and herbs that grow between its tussocks. The natural grasses of the pampas are popularly divided into pasto dura (hard pasturage), which includes the large, tussock-forming species, and pasto molle (soft pasturage), the tender undergrowth. Since the advent of Europeans other forage plants have been introduced, the most successful and profitable being alfafa or lucerne (Medicago sativa), which is widely cultivated both for hay and for green pasturage for the fattening of market stock.

West of this region is a dry, sandy, semi-barren plain, called the "sterile pampas." It has large saline areas, brackish streams and lakes, and immense sandy deserts, and in singular contrast to the fertile, treeless region of the east it supports large areas of stunted trees and thorny bushes. Most prominent in this hardy but unattractive growth is the "chañar" (Guariaca or Guaria decorticans), which is characteristic of the whole area, and led Professor Griesbach to suggest the substitution of "formaciation del chañar" for "formacion del monte," the designation adopted by botanists for this particular region. The chañar is thorny and of low, irregular growth, and furnishes a strong durable wood and a sweet fruit.

The grassy plains are well watered by streams flowing to the Paraná, La Plata and coast, though some of these are brackish. There are large saline areas in northern Santa Fé, Santiago del Estero and Tucuman, and a large deposit of salt, but the greater part of the pampas plain wells cannot be sunk lower than 18 or 20 ft. without encountering brackish water. On the sterile pampas these conditions are still more common, the drainage southward through the Desaguadero and Salado being charged with saline matter. There are many saline lakes scattered over the pampas, the largest being the Mar de Chiquita, and Lake Porongos in Cordoba, the great swamps and lagoon on the lower Salado in Mendoza, and Lake Bebedero in San Juan.

The fauna of the pampas is limited to comparatively few species, all of which are found beyond its limits, also. These include the vizcacha (Lagomostomus irrichodactylus), Patagonian hare (Dolichotis patagonica), copuy (Myopotamus coypus), cut (Cavia australis), tucu-tuco (Ctenomys magellanica), jaúgar (Felis onca), puma (Felis concolor), grass-cat (resembling Felis catus), wood-cat (Felis Geoffroy), a fox-like dog (Felis pfzieres, Azara), aguará (akin to Canis jubatus), skunk, weasel (Gallicis barbare), deer (Cervus campestris), four species of armadillo, and two of the opossum. Hudson considers the burrowing vizcacha, or biscacha, the most characteristic denizen of the pampas, though the large yellow opossum (Dolichotis cuca data) seems to be singularly adapted to life on the level grassy plain. The avifauna is apparently richer, owing to migration. Hudson enumerates 18 species of storks, ibises, herons, spoon-bills and flamingoes, 20 species of ducks, geese and swans, 10.12 the partridges, including the burrow of the vizcacha. Among other species of land birds, some 40 in number, are the military stargar (Sturnella), whose red breast makes it a conspicuous object on the pampas, the white-banded mocking-bird, the chahor or phalensus (sacating, resembling the sandgrouse, rallids, or South American ostrich. There are two species of the tinamou—the rufous and spotted—which are often carried partridges and are often hunted with snares by horsemen. The rhea, once common, is now found farther inland than formerly, and is steadily diminishing in number.

Civilized occupation is working many changes in the character and appearance of the pampas. The first change was in the introduction of cattle and horses. Cattle were pastured on the open pampas and were guarded by men called gauchos or mestizos, who became celebrated for their horsemanship, their hardihood and their lawlessness. Attention was then turned to sheep-breeding, which developed the pampas into a vast sheep pasturage. Then followed the extensive cultivation of cereals, forage crops, &c., which led to the general use of fences, the employment of immigrant labourers, largely Italian and Spanish, the building of railways and the growth of the cattle region. The gauchos, the gauchito gauchito and the land-dispossers in the eastern provinces, and the herds and flocks are being driven farther inland. The rural population of the pampas is still sparse and the estancias are very large.

W. H. Hudson, The Naturalist in La Plata (London, 1895); Charles Darwin, Voyage of the Beagle (London, 1839 and 1889); and Richard Napp, La republica argentina (Buenos Aires, 1876; also in German).

PAMPERO, the cold south-west wind which blows over the great plains of southern Argentina. The term is somewhat loosely applied to any strong south-west wind in that region, but more strictly to a rain squall or thunderstorm arising suddenly in the prevailing currents from north and north-east. Pamperos are experienced at Buenos Aires on an average about a dozen times in the year, chiefly during October, November and January.

PAMPILHIS (1st century A.D.), a Greek grammatician, of the school of Aristarchus. He was the author of a comprehensive lexicon, in 95 books, of foreign or obscure words (γλαρα και φροι δεξες), the idea of which was credited to another grammatician, Zopyrion, himself the compiler of the first four books. The work itself is lost, but an epitome by Diojenianus (2nd century) formed the basis of the lexicon of Hesychius. A similar compilation, called Λεξικον ("meadow"; cf. the Prata of Suetonius) from its varied contents, dealing chiefly with mythological marvels, was probably a supplement to the lexicon, although some scholars identify them. Pampilhis was one of the chief authorities used by Athenaeus in the Deipnosophists. Suidas assigns to another Pampilhis, simply described as "a philo- pher," a number of works, some of which were probably by Pampilhis the grammarian.

PAMPILHIS, an eminent promoter of learning in the early church, is said to have been born, of good family, in Phoenicia (Berytus?) in the latter half of the 3rd century. After studying at Alexandria under Piersus, the disciple of Origen, he was ordained presbyter at Caesarea in Palestine. There he established a theological school, and warmly encouraged students. He also founded, or at least largely extended, the great library to which Eusebius and Jerome were afterwards so much indebted. He was very zealous in the transcription and distribution of copies of Scripture and of the works of various Christian writers, especially of Origen; the copy of the complete works of the last-named in the library of Caesarea was chiefly in the handwriting
of Pamphilus himself. At the outbreak of the persecution under Maximin, Pamphilus was thrown into prison (A.D. 307) and there, along with his attached friend and pupil Eusebius (sometimes distinguished as Eusebius Pamphilus), he composed an *Apology for Origen*, in five books, to which a sixth was afterwards added by Eusebius. He was put to death in 309 by Firmilian, prefect of Caesarea.

**Pamphilus**, a Greek painter of the 4th century, of the school of Sicily. He was an academic artist, noted for accurate drawing, and obtained such a reputation that not only could he charge his pupils great sums, but he was also successful in introducing drawing in Greece as a necessary part of liberal education.

**Pamphlets.** The earliest appearance of the word is in the *Philobiblon* (1344) of Richard de Bury, who speaks of "pamphletos exiguous" (libelli breviores), and in Caxton's *Pamphilus* († Test. Ebor. i., 1495, of pamphilus (Test. Ebor. i., bl. iiii.)). O'cleave's "Though that this pamphlet" (Reg. of Pr. 1560), Lydgate's "Which is a pamphlet" (Minor Poems, 1560), and Caxton's "paumflet" (Book of Eneydus, 1490, Prologue). In all these examples pamphlet is used to indicate the extent of the production, and in contradistinction to book. A short codicil in a will of 1495 is called "this pamphlet" (Test. Ebor. iv. 26). In the 17th century the word was used for single plays, poems, newspapers, and news letters (Murray's *New English Dict.* vii. 410).

Not till the 18th century did pamphlet begin to assume its modern meaning of prose controversial tract. "Pamphlet" and "pamphlétaire" are of comparatively recent introduction into French from the English, and generally indicate fugitive criticism of a more severe, not to say libellous, character than with us. The derivation of the word is a subject of contention among etymologists. The supposed origin from the anamatory poem of "Pamphilus," and a certain Pamphila, an author of the 1st century, may be dismissed as fanciful. The experts are agreed that it is what is actually understood by a pamphlet. Some bibliographers apply the term to everything, except periodicals, of quarto size and under, if not more than fifty pages, while others would limit its application to two or three sheets of printed matter which have first appeared in an unbound condition. These are merely peculiar peculiarities, and include academical dissertations, chap-books and broadsides, which from their special subjects all belong to a separate class from the pamphlet proper. As regards its literary characteristics, the chief notes of a pamphlet are brevity and spontaneity. It has a distinct aim, and relates to some matter of current interest, whether personal, religious, political, or literary. Usually intended to support a particular line of argument, it may be descriptive, controversial, didactic or satirical. It is not so much a class, as a form of literature, and from its ephemeral character represents the changeable currents of public opinion more closely than the only consistent of the press has insisted on this important point. The history of pamphlets being the entire record of popular feeling, all that is necessary here is to briefly indicate the chief families of political and religious pamphlets which have exercised marked influence, and more particularly in those countries—England and France—where pamphlets have made so large a figure in influencing thoughts and events. It is difficult to point out much in ancient literature which precisely answers to our modern view of the pamphlet. The *libelli famosi* of the Romans were simply abusive pamphlets. Some of the small treatises of Lucian, the lost *Anti-Cato* of Caesar, Seneca's *Apocolocyntosis* written against Claudius, Julian's *Philabaer* in 20 books and *Antiopis* in 12, from their general application, just escape the charge of being mere satires, and may therefore claim to rank as early specimens of the pamphlet.

At the end of the 14th century the Lollard doctrines were widely circulated by means of the tracts and leaflets of Wycliff and his followers. The *Ploughman's Prayer* and *Lantern of Light*, which appeared about the time of Oldcastle's martyrdom, were extremely popular, and similar brief vernacular pieces became so common that it was thought necessary in 1418 to enact that persons in authority should search out and apprehend all persons owning English books. The printers of the 15th century produced many controversial tractates, and Caxton and Wynkin de Worde printed in the lesser form. It was in France that the printing-press first began to supply reading for the common people. During the last twenty years of the 15th century there arose an extensive popular literature of farces, tales in verse and prose, satires, almanacs, &, extending to a few leaves apiece, and circulated by the itinerant booksellers still known as colporteurs. These folk-books soon spread from France to Italy and Spain, and were introduced into England at the beginning of the 16th century, doubtless from the same quarter, as most of our early chap-books are translations or adaptations from the French. Another form of literature even more so than the broadsheet was the broadside, or single sheet printed on one side only, which was extensively used in England, but which had been in use from the first invention of printing for papal indulgences, royal proclamations and similar documents. Throughout western Europe, about the middle of the 16th century, the broadside made a considerable figure in times of political agitation. In England it was chiefly used for ballads, which soon became so extremely popular that during the first ten years of the reign of Elizabeth the names of no less than forty ballad printers appear in the Stationers' registers.

The humanist movement at the beginning of the 16th century produced the famous *Epistolae obscurorum vivorum*, and the leading spirits of the Reformation period—Erasmus, Hutten, Luther, Melanchthon, Francowitz, Vergerio, Curio and Calvin—found in tracts a ready method of widely circulating their opinions. The course of ecclesiastical events was precipitated in England by the *Supplication* of the Beggars (1528) of Simon Fanue, translated by Sir Thomas More's *Supplication of Poor Souls*. In the time of Edward VI, brief tracts were largely used as a propagandist instrument in favour of the Reformed religion. The licensing of the press by Mary greatly hindered the production of this kind of literature. From about 1570 there came an unceasing flow of Puritan pamphlets, of which more than forty were reprinted under the title of *A parte of a register* (London, Waldegrave, 410). In 1584 was published a tract entitled *A briefe and plaine Declaration concerning the desires of all those faithful ministers that have and do seeke for the discipline and reformation of the Church of Englands*, believed to have been written by W. Fulke D.D. Against this John Bridges, dean of Sarum, preached at Paul's Cross, and expanded his sermon into what he called *A defence of the government established in the church of Englands* (1587), which gave rise to *Oh read over D. John Bridges ... Printed at the cost and charges of M. Marprelate gentleman* (1588), which first gave the name of Marprelate to pamphlets, whose titles sufficiently indicate their opposition to priestly orders and episcopacy. Bishop Cooper's *Admonition to the People of England* (1589) came next, followed on the other side by *Hay any wryke for Cooper ... by Martin the Metropolian*, and by others from both parties to the number of about thirty-two. The controversy lasted ten years, and ended in the discomfiture of the Puritans and the seizure of their secret press. The writers on the Marprelate side are generally supposed to have been Penny, Throgmorton, Udall and Fenner, and their opponents Bishop Cooper, John Lilly and Nash.

As early as the middle of the 16th century we find ballads of news; and in the reigns of Elizabeth and James I. small pamphlets, translated from the German and French, and known as "newsbooks," were circulated by the so-called "Mercury-women." These were the immediate predecessors of weekly newspapers, and continued to the end of the 17th century. A proclamation
PAMPHLETS

was issued by Charles II., on the 12th of May 1680, "for suppressing the printing and publishing of unlicensed news-books and pamphlets of news."

In the 17th century pamphlets began to contribute more than ever to the formation of public opinion. Nearly one hundred were written by or about the restless John Lilburne, but still more numerous were those of the undaunted Pryyne, whom he himself published above one hundred and sixty, besides many weighty folios and quartos. Charles I. found energetic supporters in Peter Heylin and Sir Roger L'Estrange, the latter noted for the coarseness of his pen. The most distinguished pamphleteer of the period was John Milton, who began his career in this direction by five anti-episcopal tracts (1641-1642) during the Smeatymyns quarrel. In 1643 his wife's dissertation caused him to publish anonymously "Doctrine and discipline of divorce," followed by several others on the same subject. He printed "Of Education; to Mr. Samuel Hartlib in 1644, and, unlicensed and unregistered, his famous "Aretaplogistica—a speech for the liberty of unlicensed printing." He defended the trial and execution of the king in "Tenure of kings and magistrates" (1648). The Eikon Basilike dispute was conducted with more ponderous weapons by his sect at Westminster. The Monk held supreme power Milton addressed to him "The present means of a free commonwealth and Readie and easie way" (1660), both pleading for a commonwealth in preference to a monarchy. John Goodwin, the author of "Obstructors of Justice" (1649), John Phillips, the nephew of Milton, and Abiezer Coppe were violent and prolific partisan writers, the last-named specially known for his extreme Presbyterian principles. The tract "Killing no murder" (1652), aimed at Cromwell, and attributed to Colonel Titus or Colonel Sexby, excited more attention than any other political effusion of the time. The history of the Civil War period is told day by day in the well-known collection made by George Thomason the bookseller, now preserved in the British Museum. It includes pamphlets, books, newspapers and MSS. relating to the Civil War, the Commonwealth and Restoration, and numbers 22,255 pieces ranging from 1640 to 1661, and is bound in 2008 volumes. Each article was dated by Thomason at the time of acquisition. William Miller was another bookseller famous for his collection of pamphlets (1600-1710), which were catalogued by Tooke. William Laycock printed a "Proposal for raising a fund" for buying them up for the nation.

The Catholic controversy during the reign of James II. gave rise to a multitude of books and pamphlets, which have been described by Peck ("Catalogue, 1735") and by Jones ("Catalogue, Chetham Society, 2 vols., 1859-1865"). Politics were naturally the chief feature of the floating literature connected with the Revolution of 1688. The political tracts of Lord Halifax are interesting both in matter and manner. He wrote "The character of a trimmer" (1688), circulated in MS. as early as 1685. About the middle of the reign Defoe was introduced to William III., and produced the first of his pamphlets on occasional conformity. He issued in 1697 his two defences of standing armies in support of the government, and published sets of tracts on the partition treaty, the union with Scotland, and many other subjects. His "Shortest Way with the Dissenters" (1702) placed him in the pillory.

Under Queen Anne pamphlets arrived at a remarkable degree of importance. Never before or since has this method of publication been used by such masters of thought and language. Political writing of any degree of authority was almost entirely confined to pamphlets. If the Whigs were able to command the services of Addison and Steele, the Tories fought with the terrible pen of Swift. Second in power if not in literary ability were Bolingbroke, Somers, Atterbury, Prior and Pulteney. The government viewed with a jealous eye the free use of this powerful instrument, and St John seized upon fourteen booksellers and publishers in one day for "libels" upon the administration (see "Annals of Queen Anne", Oct. 23, 1711). In 1712 a duty was laid upon newspapers and pamphlets, displeasing all parties, and soon falling into disuse. Bishop Hoadly's sermon on the kingdom of Christ (1717), denying that there was any such thing as a visible Church of Christ, occasioned the Bangorian controversy, which produced nearly two hundred pamphlets. Soon after this period party-writing declined from its comparatively high standard and fell into meaner and viler hands. Under George III. But took Dr Shebbeare from Newgate in order to employ his pen. The court party received the support of a few able pamphlets, among which may be mentioned "The consideration of the German War against the policy of Pitt," and "The prerogative droit de Roy" (1754) vindicating the prerogative. We must not forget that although Samuel Johnson was a pensioned scribe he has for an excuse that his political tracts are his worst performances. Edmund Burke, on the other hand, has produced in this form some of his most valued writings. The troubles in America and the union between Ireland and Great Britain are subjects which are abundantly illustrated in pamphlet literature.

Early in the 19th century the rise of the quarterly reviews threw open a new channel of publicity to those who had previously used pamphlets to spread their opinions, and later on the rapid growth of monthly magazines and weekly reviews afforded them means of distribution which they could ensure by an isolated publication. Although pamphlets are no longer the sole or most important factor of public opinion, the minor literature of great events is never likely to be entirely confined to periodicals. The following topics, which might be largely increased in number, have each been discussed by a multitude of pamphlets, most of which, however, are likely to have been hopeless aspirants for a more certain means of preservation: the Bullion Question (1781), the Poor Laws (1828-1834), "Tracts for the Times" and the ensuing controversy (1834-1845), Dr Hampden (1836), the Canadian Revolt (1837-1838), the Corn Laws (1841-1848), Gorham Controversy (1849-1850), Crimean War and Indian Mutiny (1854-1859), Schleswig-Holstein (1863-1864), Ireland (1868-1869), the Franco-German War, with "Dame Europa's School" and its imitators (1870-1871), Vaticanism, occasioned by Mr Gladstone's "Vatican Decrees" (1874), the Eastern Question (1877-1878), the Irish Land Laws (1880-1882), Ireland and Home Rule (1885-1886), South African War (1899-1902) and Tariff Reform (1903).

France.—The activity of the French press in putting forth small tracts in favour of the Reformed religion caused the Sorbonne in 1523 to petition the king to abolish the diabolical art of printing. Even one or two sheets of printed matter were found too cumbersome, and single leaves or placards were issued in such numbers that they were the subject of a special edict on the 28th of September 1553. An "ordonnance" of February 1586 was specially directed against libellous pamphlets and those who wrote, printed or even possessed them. The rivalry between Francis I. and Charles V. gave rise to many political pamphlets, and under Francis II. the Guises were attacked by similar means. Fr. Hotman directed his "Epistre envoyée au tygre de France" against the Cardinal de Lorraine. The Valois and Henry III. in particular were severely handled in "Les Hémaphrodites" (c. 1659), which was followed by a long series of imitations. Between Francis I. and Charles IX. the general tone of the pamphlet literature was grave and pedantic. From the latter period to the death of Henry IV. it became more crude and dangerous.

The "Saiyre Mënippe" (1594), one of the most perfect models of the pamphlet in the language, did infinite harm to the League. The first "passion" was written against them and another defended the order in "Chasue du renard Pasquier" (1603), the latter person being their vigorous opponent Étienne Pasquier. On the death of the king the country was filled with appeals for revenge. The greatest of these were the leaflets for the imprisonment of the known of them was the "Anti-Coton" (1611), generally attributed to César de Plaix. During the regency of Mary de' Medici the pamphlet changed its severer form to a more facetious type. In spite of the danger of such proceeding under the uncompromising ministry of Richelieu, there was no lack of libels upon him, which were even in most instances printed in France. These largely increased during the Fronde, but it was Mazarin who was the subject of more of this literature than any other historical
personage. It has been calculated that from the Parisian press alone there came sufficient Maizanides to fill 150 quarto volumes each of 400 pages. Eight hundred were published during the siege of Paris (Feb. 8 to March 11, 1649). A collection of satirical pieces by the Duke de Guise's secretary, Michel Fouquet, and Colbert (1693). Pamphlets dealing with the amours of the king and his courtiers were in vogue in the time of Louis XIV., the most cautious of them being the Carte geographique de la (1700). During this period, England and the other Protestant Countries teemed with tracts against Colbert, Le Tellier, Louvois and Pére Lachaise. The first of the ever-memorable Provinciales appeared on the 23rd of January 1656, under the title of Lettre de Louis de Montesquieu a un provincial de ses amis, and the first eighteen came out at regular intervals during the next fifteen months. They excited extraordinary attention throughout Europe. The Jesuit replies were feeble and ineffectual. John Law and the schemes of the Bubble, and the declaration of the London and Parisian Whigs and Incredibilists, were the objects of the pamphlet for the next forty years. During the last reign of Louis XV., the distinguished names of Voltaire, Rousseau, Montesquieu, Diderot, D'Alembert, D'Holbach, Helvétius and Beaumarchais must be added to the list of writers in this class.

The general struggle between the parliament and the Crown gave rise to hundreds of pamphlets, which grew still more numerous as the Revolution approached. LIngnet and Mirabeau began their appeals to the people. Camille Desmoulins came into notice as a publicist during the elections for the states-general; but perhaps the piece which caused the most sensation was the Qu'est ce que le Tier État (1789) of the Abbé Sieyès. The Domine salutem fac regem and Pange lingua (1789) were two royalist pamphlets of uncommon merit. The medium for the object of the revolution and indirect defence (see H. d'Almeiras, Marie Antoinette et les pamphlets, 1807). The financial disorders of 1790 occasioned the Essais des assignats on pour le prix du pan de Dupont de Nemours; and the Leibnizian pamphlet of the Vrai mirroir de la noblesse dragged the titles of France through the mire. The massacre of the Champ de Mars, the death of Mirabeau, and the flight of the king in 1791, the nobles of Lyons and the military struggle between the parliament and the Crown gave rise to hundreds of pamphlets, more or less violent in tone. Perhaps the most complete collection of French revolutionary pamphlets is that in the Bibliothèque Nationale of Paris. The first was Le Pétition de Paul Louis Courier, the first of those brilliant productions of a master of the art. He gained the distinction of judicial procedure with his Simple Discours in 1812, and published in 1824 his last political work, Le Pamphlet des pamphlets, the most eloquent justification of the pamphlet ever penned. The Mémoire à consoler de Montosier attacking the growing power of the Congregation. The year 1827 saw an augmentation of severity in the press laws and an increase in the number and weight of pamphlets. The press conscience, however, improved in power and activity, but found its greatest support in the songs of Béranger and the journalism of Mignet, Thiers and Carrel. M. de Commenan was the chief pamphleteer of the reign of Louis Philippe, and his pamphlets were the most excellent. During 1830 there was no lack of violent apologies of the coup d'état. The second empire suffered from many bitter attacks, among which may be mentioned the Lettre sur l'histoire de France (1851) of the Duc d'Aumale, Propos de Labbé (1865) of Roger, Dialogue aux enfers (1864) of Maurice Joly, Comptes fantastiques d'Haussmann (1868). In more recent times the Panama prosecutions and the Dreyfus case gave occasion to an immense pamphlet literature.

Germany.—In Germany, the cradle of printing, the pamphlet (Plugschrift) was soon a recognized and popular vehicle of thought, and the fierce religious controversies of the Reformation period afforded a unique opportunity for its use. The employment of the pamphlet in this connexion was characteristic of the new age. In coarse and violent language the pamphlets appealed directly to the people, whose sympathy the leaders of the opposing parties were most anxious to secure, and their issue on an enormous scale was undoubtedly one of the most powerful means of propaganda. The German Reformation, the French Revolution, and the Roman Catholic Church. In general their tone was extremely intertemperate, and they formed, as one authority has described them of a century later, “a mass of panegyric, adulation, invective, controversy and scurrility.” Luther was one of the earliest and most effective writers of the polemical pamphlet. His adherents quickly followed his example, and his opponents also were not slow to avail themselves of a weapon which was proving itself so powerful. So intense at this time did this pamphlet war become that Erasmus wrote “apud Germanos, vix quicquam vendibile est praeter Lutheranæ ac anti Lutheranæ.”

A remarkable feature was the coarseness of many of these pamphlets. No sense of decency or propriety restrained their writers in dealing either with sacred or with secular subjects, and this was the result of the feeling that the Church was alarmed by the remarkable growth of disorder, attributable in part at least to the wide circulation of pamphlet literature. Accordingly the issue of libellous pamphlets was forbidden by order of the diet in 1523, and again by the decrees of Speyer in 1529, Augsburg in 1530 and of Regensburg in 1541, while in 1589 the emperor Rudolph II. fulminated against them.

The usual method of selling these pamphlets was by means of book-sellers, itinerant booksellers, and book-stalls and book-sellers. The most remarkable of these were among the foremost to use pamphlets in this connexion, especially perhaps Maximilian of Bavaria and Christian of Anhalt.

LITERATURE.—An excellent catalogue by W. Olds of the pamphlets published in England from the accession of James II, to 1714, is in the second edition of the Miscellany by T. Park; and in the Bibliotheca valente di G. Cinielli (2nd ed. 4 vols, 1734-1742) may be seen a bibliography of pamphlet literature, chiefly Italian and Latin, with notes. See also Cat. of the pamphlets in the British Museum, etc., in the British Museum on the French Rev., 1899; Cat. of the Thomasset books, pamphlets, etc., 1908, 2 vols. A few of the more representative collections of pamphlets in English may be mentioned. For a more complete list of the pamphlets of John Bunyan, see F. D. C. C. Wright's Catalogue (London, 1889-1905), giving examples of political, religious and literary pamphlets.
PAMPHYLIA—PAN

Pamphylians, in ancient geography, the region in the south of Asia Minor, between Lydia and Cilicia, extending from the Mediterranean to Mt Taurus. It was bounded on the N. by Pisidia and was therefore a country of small extent, having a coast-line of only about 75 m. with a breadth of about 30 miles. There can be little doubt that the Pamphylians and Pisidians were the same people, though the former had received colonies from Greece and other lands, and from this cause, combined with the greater fertility of their territory, had become more civilized than their neighbours in the interior. But the distinction between the two seems to have been established at an early period. Herodotus, who does not mention the Pisidians, enumerates the Pamphylians among the nations of Asia Minor, while Ephorus mentions both, correctly including the Lydians among the nations on the coast, the other among those of the interior. The early Pamphylians, like the Lydians, had an alphabet of their own, partly Greek, partly "Asiatic," which a few inscriptions on marble and coins preserve. Under the Roman administration the term Pamphylia was extended so as to include Pisidia and the whole tract up to the frontiers of Phrygia and Lydia, and in this wider sense it is employed by Ptolemy.

Pamphylia consists almost entirely of a plain, extending from the slopes of Taurus to the sea, but this plain, though presenting an unbroken level to the eye, does not conceal alluvial deposits, but is broken in part of traverse. The rivers pouring out of the caverns at the base of the Lydian and Pisidian ranges of the Taurus come forth from their subterranean courses charged with carbonate of lime, and are continually adding to the Pamphylian plain. They build up natural aqueducts of limestone, and after flowing for a time on these elevated beds burst their walls and take a new course. Consequently it is very difficult to reconcile the accounts of this district, as transmitted by ancient authors, with its present aspect and the distribution of the streams which water it. By the sea-side in the west of the district the traverse forms cliffs from 20 to 80 ft. high." (Forbes's Lycia, ii. 188.) Strabo describes a river which he terms Catarractes as a large stream falling with a great noise over a lofty cliff. This is the cataract near Adalia. East of Adalia is the Cestrus, and beyond that again the Euremedon, both of which were considerable streams, navigable in antiquity for some little distance from the sea. Near the mouth of the latter was a lake called Caprias, mentioned by Strabo; but it is now a mere salt marsh.

The chief town on the coast is: Olba, the first town in Pamphylia, near the Lydian frontier; Attalia (q.v.); and Side (q.v.) and above the river Cestrus was Perga (q.v.). Between the two rivers, but somewhat farther inland, stood Syculum, a strong fortress, which even ventured to defy the arms of Alexander. These towns are not known to have been Greek colonies; but the foundation of Aspendus was traditionally ascribed to the Argives, and Side was said to be a colony from Cyme in Aeolis. The legend related by Herodotus and Strabo, which ascribed the origin of the Pamphylians to a colony led into their country by Amphiloctus and Calchas after the Trojan War, is merely a characteristic myth. The coins of Aspendus, though of Greek character, bear legends in a barbarous dialect; and probably the Pamphylians were of Asianic origin and mixed race. They became largely hellenized in Roman times, and have left magnificent memorials of their civilization at Perga, Aspendus and Side. The district is now largely peopled with recent settlers from Greece, Crete and the Balkans.

The Pamphylians are first mentioned among the nations subdued by the Mermnad kings of Lydia, and afterwards passed in succession under the dominion of the Persian and Macedonian monarchs. After the defeat of Antiochus III. in 190 B.C. they were included among the provinces annexed by the Romans to the dominions of Eumenes of Pergamum; but somewhat later they joined with the Pisidians and Cilicians in piratical ravages, and Side became the chief centre and slave market of these freebooters. Pamphylia was for a short time included in the dominions of Amyntas, king of Galatia, but after his death lapsed into a district of a Roman province, and its name is not again mentioned in history.

J. C. Lancloskis, Les Villles de la Pamphylie et de la Piridie (1890).

PAMPLONA, or Pampeluna, the capital of the Spanish province of Navarre, and an episcopal see; situated 1375 ft. above sea-level, on the left bank of the Arga, a tributary of the Ebro. Pop. (1900), 28,886. Pamplona has a station on the Ebro railway connecting Alsasua with Saragossa. From its position it has always been the principal fortress of Navarre. The old outworks have been partly demolished and replaced by modern forts, while suburbs have grown up round the inner walls and bastions. The citadel, south-west of the city, was constructed by order of Philip II. (1556-1598), and was modelled on that of Antwerp. The streets of the city are regular and broad; there are three fine squares or plazas. The most attractive of these is the arcade Plaza del Castillo, flanked by the hall of the provincial council and by the theatre. The cathedral is a late Gothic structure begun in 1397 by Charles III. (El Noble) of Navarre, who is buried within its walls; of the older Romanesque cathedral only a small portion of the cloisters remains. The fine interior is remarkable for the peculiar structure of itsapse, and for the choir-stalls carved in English oak by Miguel Ancheta, a native artist (1530). The principal façade is Corinthian from designs of Ventura Rodríguez (1748). The same architect designed the superb aqueduct by which the city is supplied with water from Monte Franco, some nine miles off. The beautiful cloisters on the south side of the cathedral, and the chapter-house beyond them, as well as the old churches of San Saturnino (Gothic) and San Nicolas (Romanesque), are also of interest to the student of architecture. There are also the bull-ring, capable of accommodating 8000 spectators, the pelota court (el Trinque) and several parks or gardens. The city is well provided with schools for both sexes; it has also a large hospital.

Pamplona has a flourishing agricultural trade, besides manufactures of cloth, linen stuffs, flour, soap, leather, cards, paper, earthenware, iron and nails. The yearly fair in connexion with the feast of San Fermin (July 7), the patron saint of the city, attracts a large concourse from all parts of northern Spain.

Originally a town of the Vascones, Pamplona was rebuilt in 68 B.C. by Pompey the Great, whence the name Pamphela or Pompeilo (Strabo). It was captured by Euric the Gothic in 466 and by the Franks under Childibert in 542; it was dismantled by Charlemagne in 776, but repulsed the emir of Saragossa in 1052. The city was strengthened and beautified by Charles III., who built a citadel on the site now occupied by the Plaza de Toros and by the Basilica of S. Ignacio, the church marking the spot where Ignatius of Loyola received his wound in defending the place against André de Foix in 1521. From 1808 it was occupied by the French until taken by Wellington in 1813. In the Carlist War of 1836-40 it was held by the Cristinos, and in 1875-76 it was more than once attacked, but never taken, by the Carlists.

PAN, in Greek mythology, son of Hermes and one of the daughters of Dryops ("oak-man"), or of Zeus and the nymph Callisto, god of shepherds, flocks and forests. He is not mentioned in Homer or Hesiod. The most poetical account of his birth and life is given in the so-called Homeric hymn To Pan. He was born with horns, a goat's beard and feet and a tail, his person being completely covered with hair. His mother was so alarmed at his appearance that she fled; but Hermes took him to Olympus, where he became the favourite of the gods, especially Dionysus. His life and characteristics are typical of the old shepherds and goatherds. He was essentially a rustic god, a wood-spirit conceived in the form of a goat, living in woods and caves, and traving the tops of the mountains; he protected and gave fertility to flocks; he hunted and fished; and sported and danced with the mountain nymphs. A lover of music, he invented the shepherd's pipe, said to have been made from the reed into which the nymph Syrinx was transformed.
PAN—PANAETIUS

The Hindostani pān is the betel-leaf, which, mixed with areca-nut, lime, &c., is chewed by the natives of the East Indies.

The common prefix “pan,” signifying universal, all-embracing (Greek πᾶς, “all”), is often combined with the names of races, nationalities and religions, conveying an aspiration for the political or spiritual union of all the units of the nation or creed; familiar examples are Pan-Slavonic, Pan-German, Pan-Islamism, Pan-Anglican, Pan-American.

PANA, a city of Christian county, Illinois, U.S.A., in the central part of the state. Pop. (1900) 5530 (772 being foreign-born); (1910) 6055. It is served by the Baltimore & Ohio Southwestern, the Cleveland, Cincinnati, Chicago & St Louis, the Illinois Central and the Chicago & Eastern Illinois railways. It is in the Illinois coal region, and coal-mining is the most important industry; the city is also a shipping point for hay and grain grown in the vicinity. Pana was incorporated in 1857, and was reincorporated in 1877. Its name is said to be a corrupt form of "Pani" (Pawnee), a name of a tribe of Indians.

PANACEA (Gr. πανακεία, all-healing, from πᾶς, all, and ἰαύσθα, to heal), a universal remedy, or cure for all diseases, a term applied in the middle ages to a mythical herb supposed to possess this quality. Many herbs have had the power of curing all diseases attributed to them, and have hence had the name of "all-heal," such as have been, among others, the mistletoe, the sandworts (Stachys palustris), the yarrow or milfoil, and the great valerian.

PANACHE, a French word adapted from Ital. pennachio, Lat. penna, feather, for a plume of feathers on a helmet or hat; the "panache" should be properly distinguished from the "plume," as being a large cluster of feathers fixed on the top of the helmet and flowing over it, the "plume" being a single feather at the side or front. The word "panache" is often used figuratively in French of a flamboyant piece of ornamentation, a "purple patch" in literature, or any exaggerated form of decoration.

PANAENUS, brother of Phileias, a Greek painter who worked in conjunction with Polygnotus and Micon at Athens. He also painted the marble sides of the throne of the statue of Zeus erected by his brother at Olympia.

PANAETIUS (c. 185-180 to 110-108 B.C.), Greek Stoic Philosopher, belonged to a Rhodian family, but was probably educated partly in Pergamum under Crates of Mallus and afterwards in Athens, where he attended the lectures of Diogenes the Babylonian, Critolaus and Carneades. He subsequently went to Rome, where he became the friend of Laelius and of Scipio the Younger. He lived for a time in the house of the latter, and accompanied him on his mission to Egypt and Asia (143 or 141). He returned with Scipio to Rome, where he did much to introduce Stoic doctrines and Greek philosophy. He had a number of distinguished Romans as pupils, amongst them Q. Mucius Scaevola the augur and Q. Aelius Tubero. After the murder of Scipio in 129, he resided by turns in Athens and Rome, but chiefly in Athens, where he succeeded Antipater of Tarsus as head of the Stoic school. The right of citizenship was offered him by the Athenians, but he refused it. His chief pupil in philosophy was Posidonius of Apamea. In his teaching he laid stress on ethics, and his most important works, of which only insignificant fragments are preserved, were on this subject. They are as follow: Πείπτω κδήσσως (On Duty), in three books, the original of the first two books of Cicero's De officiis; Πείπτω προνυμίου (On Providence), used by Cicero in his De divinatione (ii.) and probably in part of the second book of the De Deorum natura; a political treatise (perhaps called Πείπτω προκαράτευτος), used by Cicero in his De republica; Πείπτω εὐρυθυάς (On Cheerfulness); Πείπτω αἴρεταν (On Philosophical Schools); a letter to Q. Aelius Tubero, De dolore patiendo (Cicero, De familia, iv. 9, 23).

Edition of the fragments by H. N. Fowler (Bonn, 1885), and in F. van Lynden's monograph (Leiden, 1802). See also A. Schmekel, Die Philosophie der mittleren Sota (1892); F. Susmelich, Geschichte der griechischen Literatur in der Alexandrinzeit (1892), ii. 63-80; E. Zeller, "Beiträge zur Kenntniss des Stoikers Panaitios" in Commen- tationes philologicae in honore Th. Mommsen (1877).

When fleeing from his embraces (Ovid, Metam. i. 691 sqq.). With a kind of trumpet formed out of a shell he terrified the Titans in their fight with the Olympian gods. By his unexpected appearance he sometimes inspires men with sudden terror—hence the expression "panic" fear. Like other spirits of the woods and fields, he possesses the power of inspiration and prophecy, in which he is said to have instructed Apollo. As a natural god he was brought into connexion with Cybele and Dionysus, the latter of whom he accompanied on his Indian expedition. Associated with Pan is a number of Panisci, male and female forest imp, his wives and children, who send evil dreams and apparitions to terrify mankind. His original home wasArcadia; his cult was introduced into Athens at the time of the battle of Marathon, when he promised his assistance against the Persians if the Athenians in return would worship him. A cave was consecrated to him on the north side of the Acropolis, where he was annually honoured with a sacrifice and a torch-race (Herodotus vi. 103). In later times, by a misinterpretation of his name (or from the identification of the Greek god with the ram-headed Egyptian god Chnum, the creator of the world), he was pantheistically conceived as the universal god (τό πᾶς). The pine and oak were sacred to him, and his offerings were goats, lambs, cows, new wine, honey and milk. The Romans identified him with Innuus and Faunus.

In art Pan is represented in two different aspects. Sometimes he has goat's feet and horns, curly hair and a long beard, half animal, half man; sometimes he is a human figure with long flowing hair, generally characterized by horns just beginning to grow, the shepherd's crook and pipe. In bas-reliefs he is often shown presiding over the dances of nymphs, whom he is sometimes pursuing in a state of intoxication. He has furnished some of the attributes of the ordinary conception of the devil. The story (alluded to by Milton, Rabelais, Mrs Browning and Schiller) of the pilot Thamus, who, sailing near the island of Paxi in the time of Tiberius, was commanded by a mighty voice to proclaim that “Pan is dead,” is found in Plutarch (De orac. dictecta, 17). As this story coincided with the birth (or crucifixion) of Christ it was thought to herald the end of the old world and the beginning of the new. According to Roscher (in Neue Jahrbiicher für Philologie, 1892) it was of Egyptian origin, the name Thamus being connected with Thmous, a town in the neighbourhood of Mendes, distinguished for the worship of the ram; according to Herodotus (ii. 46), in Egyptian the goat and Pan were both called Mendes. S. Reinach suggests that the words uttered by the “voice” were Θαμύς, Θαμύς, πάμιγματι, τέιμνημι (“Tammuz, Tammuz, the all-great, is dead”), and that it was merely the lament for the “great Tammuz” or Adamis (see L. R. Farnell in The Year's Work in Classical Studies, 1907).

See W. Gebhardt, Pankultus (Brunswick, 1872); P. Wetzel, De Jove et Pane dis arcidentes (Breslau, 1873); W. Vater, Kultur, Kunde und Mythen der Araber, (1881), vol. i, and V. Berard, De l'Origine des cultes arcaidentes (1894), who endeavoured to show that Pan is a sun-god (see below); articles by W. H. Roscher in Lexicon der Mythologie and by J. A. Hild in Daremburg and Saglio's Dictionnaire des Antiqutes; E. E. Sikes in Classical Review (1895), ix. 70; O. Gruppe, Griechische Mythologie (1906), vol. ii.

PAN (common in various forms to many Teutonic languages, cf. Ger. Pflanne; it is generally taken to be an early adaptation in a shortened form of Lat. patina, shallow bowl or dish, from patere, to lie open), a term applied to various sorts of open, flat, shallow vessels. Its application has been greatly extended by analogy, e.g. to the upper part of the skull; to variously shaped objects capable of retaining substances, such as that part of the lock in early firearms which held the priming (whence the expression "flash in the pan," for a premature and futile effort); or the circular metal dish in which gold is separated from gravel, earth, &c., by shaking or washing (whence the phrase "to wash out," to obtain a good result). Small ice-floes are also called "pans," and the name is given to a hard substratum of soil which acts as a floor to the surface soil and is usually impervious to water. For "pan" or "pane" in architecture see HALF-TIMBER WORK.
made of him by Cicero, R. Hirzel, *Untersuchungen zu Ciceros philosophischen Schriften* (1877-1883). For his importance in the Stoic succession and his philosophy generally, see *Stoics*.

**PANAMA**, a Central American republic, occupying the Isthmus of Panama, and lying approximately between 7° 15' and 9° 39' N. and between 77° 15' and 85° 30' W. It is bounded N. by the Caribbean Sea, E. by Colombia, of which it was formerly a part, S. by the Gulf (or Bay) of Panama, an arm of the Pacific, and W. by Costa Rica. Its area is estimated at from 31,500 to 33,800 sq. m.; its greatest width is 118 m. and its greatest length 430 m.; its land frontier is only about 350 m., but on the Caribbean it has a coast of 478 m. and on the Pacific a coast of 757 m.

**Physical Features.**—The Isthmus of Panama, coextensive with the republic, is the whole neck of land between the American continents; in another use the term "Isthmus of Panama" is applied to the narrow crossing between the cities of Colon and Panama, the other narrow crossings, further east, being the Isthmus of San Blas (31 m.) and the Isthmus of Darien (46 m.). The use of the term "Isthmus of Panama" to include the whole country is becoming more common. The Caribbean coast-line is concave, the Pacific deeply convex. The Mosquito Gulf is to the N.W., the Gulf of Darien to the N.E., and on the N. coast are several small bays. The Chiriqui Bay, north of Panama, has been for 2-3 m. wide, with marshlands, and good anchorages protected by the Tubul Island, about 8 m. long; immediately east of it, and connected with it, is the Isthmus lagoon (area about 320 sq. m.), 32 m. long, 12 m. wide at the widest point, with a maximum depth of 10 ft., protected on the sea side by Chiriqui Archipelago; immediately east of Colon, at the narrowest part of the isthmus, is the Gulf of San Blas, 20 m. long and 10 m. wide, protected by a peninsula and by the Mulatos Archipelago—low, sandy islands stretching about 80 m. along the coast—and having the excellent harbour of Mandainga in the south-west; still farther east is Colonia Bay with another good harbour. On the north coast there are about 650 islands with a total area of about 10 sq. m. The Pacific coast is deeply indented by the Gulf of Panama, which is 100 m. wide between Cape Garachico and Cape Malo, and has the Bay of Parita (20 m. wide at its mouth) on its west side, north of Cape Malo, and the Gulf of San Miguel (15 m. wide at its mouth) on its east side, north of Cape Garachico. Darien Harbour, formed by the Tuira and Savannah rivers, is a part of the Gulf of San Miguel and is 11 m. long, 2-4 m. wide, and nearly landlocked. In the Gulf of Panama there are 16 large and about 100 smaller islands (the Pearl Islands), with a total area of 450 sq. m., the largest being Rey or San Miguel (15 m. long and 7 m. wide), and San Pedro (25 sq. m.); both are wooded, with mountains and hills covered by dense forests. West of the Gulf of Panama is the Isthmus Peninsula, 50 m. long and 14 m. wide at its mouth, which stretches across Cebaco Island, 135 m. long, and 3 m. wide; west of Cebaco Island is the largest island of the republic, 21 m. long and 4-12 m. wide.

The country has no lakes; the apparent exceptions are the artificial lakes, Ohio (or Gatun) and Sosa, at the Canal Zone. There are a few swamps, especially on the northern shore. But the drainage is good; about 150 streams empty into the Caribbean and 35 into the Pacific. In the eastern part are three complicated drainage systems of rivers very largely tidal, the large part of which flow from the Tuira (formerly called Rio Darien), whose headwaters are near the Caribbean and which empties into the Pacific in the Gulf of San Miguel. The Chepo (or Bocaya) also is a digitate system with a drainage basin of 850 sq. m., from which flows a large river which empties into the Pacific; it is navigable for about 120 m. by small boats. The Chagres flows from a source near the Pacific south-west and then north to the Caribbean; it is a little more than 100 m. long and is navigable for about half that distance; it varies greatly in depth, sometimes rising 60 ft. in a few minutes. West of these three rivers are simpler and comparatively unimportant river systems, rising near the centre of the isthmus. Orographically the country is remarkable. The "exceedingly irregularly rounded, low-crowned" system of the drainage basins (as it is called) is strongly marked, with the Andes, not Andean, and lie at right angles to the axes of the systems of North and South America. The only regular ranges in Panama are in the extreme western part where the Costa Rica divide continues into Panama, and, immediately south of this and parallel to it, the Cordiller of San Blas, or Sierra de Chiriqui, where the highest peaks are Chiriqui (11,265 ft.) and, on the Costa Rican

**boundary,** Pico Blanco (11,740 ft.) and Rovalo (7020 ft.); there are two passes, 3600 and 4000 ft. high respectively. On the eastern boundary of the republic is the Serranía del Darien, an Andean range, partly in Colombia. The rough country between contains the following so-called Sierra's, which are not really ranges: in Veraguas, Sierra de Veraguas, with Santiage (2075 ft.) and, near the Chiriqui range, and Santa Maria (4000 ft.); immediately north of the city of Santa Fe; in Los Santos province (Azuero Peninsula), bold hills rising 3000 ft.; in Panama province, the mountain ranges; and during the wet season it is possible to see the bold and rugged islands, notably those in the Gulf of Panama. It is improbable that there has been any connexion by water between the two oceans here since Tertiary time.

**Communications.**—The mean temperature varies little throughout the republic, being about 80° F. at Colon, where 68° is a low and 95° a high temperature, the mean is 71°; at Panama the mean is 80°-6. But this difference is not the usual one: normally the Caribbean coast is a degree or two warmer than the Pacific coast. The mean temperature at Colon, during the middle of April to the middle of December, there falls (in heavy, short rains) about 85% of the total annual precipitation, and south-east winds prevail. The north-east winds prevail in the dry season, which is during the two months of April. Rainfall varies from 55 to 155 in., with 125 as the mean; at Gamboa in the interior it varies from 75 to 120 in., with 92 as the mean; and at Panama on the south coast it varies between 47 and 90 (rarely 104 in.), the mean being 79 in.

**Natural Resources.**—Gold is mined to a small extent; the most productive mines are about Darien and in Colon province. Copper has been found between the Plain of David and Bocas del Toro. There are valuable deposits of coal near Bocas del Toro and Golfo Dulce. The total value of the products, 85% of which go to the United States, amounted to $1,879,297; in 1908 the value was $7,806,811 (vegetable products, $1,757,297; agricultural products, $1,258,900; tobacco products, $1,003,148; vegetable oils, $255,703; the textiles mainly from Great Britain, all other imports largely from the United States); the value of the exports was estimated at $7,157,153 (including vegetable products, mostly bananas, $3,764,153; minerals, $350,203; vegetable products, $79,620), of which $1,587,217 was the value of gold shipped to the United States, $113,058 of goods to Great Britain, and $3,495 to Germany. Besides bananas the largest exports are hides, rubber, cocnutts, limes, native curios and quino-bark. Transportation along the Canals and railroads is done by mules. The French company, under the old name of Compagnie Universelle de Canal Interoceáne de Panama, and, with the other half-breed and mixed race population, 68,689 (more than 97% of the total) passed to the

1 Christobol, the port of Colon, and Balboa, the port of Panama, lie within the Canal Zone and are under the jurisdiction of the United States.
United States government. The line of railway is very nearly that of the canal, and the work of the railway engineers was of great value to the French engineers of the canal. There are several telegraphic and telephone systems; a wireless telegraph station at Colon; and telegraphic cables from Colon and Panama which, with a connecting cable across the isthmus, give an "Island" service to the United States and to Europe. There are two old wagon roads from Panama City, one, now little used, north to Porto Bello, and the other (called the royal road) 17 m. north-west to Cruce, a point of departure on the Chagres River. Other roads are mere rough trails.

Inhabitants and Towns.—The population in 1909 was about 361,000. The inhabitants exhibit various degrees of admixture of Indian, negro and Spanish blood, with an increasing proportion of foreigners. The Indians are most numerous in the western part. The negroes, largely from Jamaica and the other West Indies, came in large numbers to work on the canal. The Spanish was the race that stood for civilization before North American influence became strong. Many Spanish peasants, Italians, and Greeks came in to work on the canal, but this is not a permanent population. As elsewhere in Spanish America, there has been a German colonization, notably in Colón province, where a large tropical estate was established in 1894.

The principal cities in Panama are: Colon (q.v.), at the Caribbean end of the canal; Panama (q.v.), at the Pacific end of the canal, and the city of Panama; and the city of La Ciudad de David (q.v.), on the Isthmus. Other important towns are: Bocas del Toro (pop. about 4000), capital of the province of the same name, in the north-western corner of the country, with a large trade in bananas and good fishing in the bay; Porto Bello (pop. about 2500), an important commercial city, in Colon province, on Porto Bello Bay, where Columbus established the colony of Nombre de Dios in 1502—the present city was founded in 1584, was often captured by the English (notably by Admiral Edward Vernon in 1739); and Chagres (pop. about 2500), in the middle of theisthmus, on the road to Panama, whence gold was brought to Porto Bello for shipment; Chagres (pop. about 2500), also in Colon province, formerly an important port, and now a fishing place; Agua Dulce, formerly called Trópico (pop. about 2000), in the centre of the isthmus industry; and San Miguel, on an island of the same name in the Gulf of Panama, the principal pearl fishery. The larger inland cities are: Ciudad de David (pop. about 8000), the capital of Chiriquí, 12 m. from the Pacific, 60 m. east of the Costa Rican boundary, with a trade in cattle; Los Santos (pop. about 10,000), the capital of Los Santos province; Santiago de Veraguas (pop. about 7000), 300 ft. above the sea, with various manufactories, gold, silver and copper mines, and mineral springs and baths near the city; Las Tablas (pop. about 6500) and Pase (pop. about 5000), in the Los Santos province; and Penonomé (pop. about 3000), on the river that makes the province of Coclé province (of which it is the capital), with a trade in straw hats, tobacco, cacao, coffee, cotton, rubber, cedar and cattleya palms. Other towns are Gorgona (3000) and Obispo (2500), each with an American colony.

Administration.—By the constitution promulgated on the 13th of February 1904 the government is a highly centralized republic. All male citizens over 21 years of age have the right to vote, except those under judicial interdiction and those judicially incapacitated by reason of crime. The president, who must be at least 35 years old, is elected by popular vote for four years, is ineligible to succeed himself and appoints cabinet members (secretaries of foreign affairs, government and justice, treasury, interior ['fomento'] and public instruction); five supreme court judges (who decide on the constitutionality of a bill voted by the president on constitutional grounds—their action, if favourable to the constitutionality of such a bill, makes the president's signature mandatory); diplomatic representatives; and the governors (annually) of the provinces, who are responsible only to him. The president's salary is $15,000 a year. There is no vice-president, but the National Assembly, when elected every four years, elects a deputy president who, after the expiration of his term, succeeds the president if he should die. The National Assembly is a single chamber, whose deputies (each at least 25 years old) are elected for four years by popular vote on the basis of 1 to every 10,000 inhabitants (or fraction over 5000); it meets biennially; by a two-thirds vote it may pass any bill over the president's veto—the president has five or ten days, according to the length of the bill, in which to veto any act of the legislature. At the head of the judiciary is the Supreme Court already referred to; the superior court and the circuit courts are composed of judges appointed for four years by the members of the Supreme Court. The municipal courts are appointed by the Supreme Court judges for one year.

The seven provinces, restoring an old administrative division, are: Panama, with most of the territory east of the canal and a little (on the Pacific side) west of the canal; Colon, on either side of the canal, along the Caribbean; Colon, west and south; Puntarenas, further west and south, on the Azuero Peninsula, west of the Gulf; Veraguas, south-west; Santa Cruz, west; and Chiriqui, farthest west, on the Pacific, and Bocas del Toro on the Caribbean. The provinces are divided into municipal districts (distritos municipales), each of which has a municipal legislature (concejo) which elects its president. The executive is vested in the governor, who is the agent of the governor of the province and is appointed annually. By the treaty of the 18th of November 1908 Panama ceded to the United States the "Canal Zone," a strip of land reaching to the west side of the isthmus and included in the Gulf of Panama; from this cession were excluded the cities of Colon and Panama, over which the United States received jurisdiction only as regards sanitation and water-supply.

Education.—The system of public education dates from the independence of Panama only and has not been developed. But primary instruction has been greatly improved; there is a school of arts and trades at the capital, in which there are endowed scholarships for pupils from different provinces; a normal school has been established in Panama for the Indians; high schools and training schools have been opened; and the government pays the expenses of several students in Europe.

Coinage and Finance.—In June 1904, under the terms of an agreement between Panama and the United States (called the "Canal Zone Agreement"), the United States government consented to pay at the rate of $100 gold for each United States silver dollar, and to use the dollar as the unit of coinage and currency. On the 30th of June 1909 the total cash assets of the government were $7,560,971, of which $6,000,000 was invested in New York City bonds. The total loans at the end of 1909 were $9,163,783. In the six months ending with that date the receipts were $1,295,574 (largely from import and export duties, and taxes on liquor, tobacco, matches, coffee, opium, salt, steamship companies and money changers), and the cash balance for the six months was $105,307.

History.—The Isthmus of Panama was probably visited by Alonso de Ojeda in 1499. In 1501 Rodrigo Bastidas coasted along the Gulf of Venezuela to the present Porto Bello. Columbus established the colony of San Miguel de la Independencia in Colon Bay, where he planted a colony (Nombre de Dios) in November; the Indians destroyed it almost immediately; it was re-established in 1510, by Diego de Nicuesa, governor of the newly established province of Castilla del Oro, which included what is now Nicaragua, Costa Rica and Panama. In 1510 Martín Fernandez de Enciso, following Alonso de Ojeda to the New World, took the survivors of Ojeda's colony of Nueva Andalucía (near the present Cartagena and east of Panama) and founded on the Tuberá river the colony of Santa María la Antigua del Darién (commonly called Darién). An insurrection against Enciso in December 1510 put in command Vaso Núñez de Balboa, who accompanied Rodrigo de Bastidas in the voyage of 1501. In September 1513 Núñez crossed the isthmus and (on the 25th or 26th) discovered the Pacific. Immediately afterwards he was succeeded by Pedro Arias de Avilés, by whom Nueva Andalucía and Castilla del Oro were united in 1514 under the name of Tierra Firme, and who founded in 1515 the city of Panama, now the oldest European settlement on the mainland in America. The portage between the two oceans was of great importance to the Spanish treasure fleets. In 1555, when the treasure from Peru (and treasure was the raison d'etre of the Spanish settlements in Panama) was carried across the isthmus from Panama City. A Scotch settlement under letters patent from the Scotch Parliament was made by William Paterson (q.v.) in 1568 on the site of the present Porto Sococo (in the north-eastern part of the republic), but in 1700 the Spanish authorities expelled the few settlers still there. Panama was a part of the vicerealty of New Granada created in 1718, and in 1819 became a part of the independent nation of Colombia and in 1831 of New Granada, from which in 1841 Panama and Veraguas provinces seceded as the state (short-lived) of the Isthmus of Panama.
The constitution of the Granadine Confederation of 1853 gave the states the right to withdrew, and in 1857 Panama 1 again seceded, soon to return. When núñez in 1885 disregarded the constitution of 1853, which made Panama a province of states severely sovereign, he was strongly opposed by the people of Panama, who had no actual representation in the convention which made the constitution of 1886, an instrument allowing Panama (which it made a department and not a state) no local government. The large expenditures of the French canal company made the department singularly alluring to corrupt officials of the central government, and Panama suffered severely before the liquidation of the company in 1889. There were risings in 1895 and in 1898-1902, the latter ceasing with American occupation.

The treaty of the United States in 1846 with New Granada, granting transportation facilities on the Isthmus to the United States, then preparing for war with Mexico, and guaranteeing on the part of the United States the sovereignty of New Granada in the Isthmus, has been considered the first step toward the establishment of an American protectorate over the Isthmus. In 1901 by the negotiation of the Hay-Pauncefote Treaty it became possible for the United States alone to build and control an interoceanic canal. The Hay-Herran Treaty of January 1903, providing that the United States take over the Panama Canal Company's rights and responsibilities, was made possible because it was hoped that settlement might be delayed until then the concession from the United States would come directly to the Colombian government; and the Congress, which had been specially called for the purpose—there was no regular legislative government in Bogotá in 1898-1903—adjourned on the 31st of October. Three days later, on the 3rd of November, the independence of Panama was declared. Commander John F. Hubbard of the United States gunboat "Nashville" at Colon forbade the transportation of Colombian troops across the Isthmus, and landed 42 marines to prevent the occupation of Colon by the Colombian force; the diplomatic excuse for his action was that by the treaty of 1846 the United States had promised to keep the Isthmus open, and that a civil war would have closed it. On the 7th of November Panama was virtually recognized by the United States, when her diplomatic representative was received; and on the 18th of November a treaty was signed between the United States and Panama, ceding to the United States the rights and responsibilities of the "Canal Zone". In return for an annual payment of $10,000,000 immediately and $750,000 annually as rental, the first payment to be made nine years after the ratification of the treaty. On the 4th of January 1904, two months after the declaration of independence, a constitutional assembly was elected, which met on the 15th of January, adopted the constitution described above, and chose as president Manuel Amador Guerrero (1834-1909). He was succeeded in October 1908 by Domingo dc Obaldia. In 1905 a treaty was made with Costa Rica for the demarcation of the boundary line between the two countries.

**PANAMA**, the capital and the chief Pacific port of the republic of Panama, and the capital of the province of the same name, in the south-central part of the country, at the head of the Gulf of Panama, and at the south terminus of the Panama railway, 47 7/10 m. from Colon, and of the Panama Canal. Pop. (1910), about 30,000, of whom nearly one-half were foreign-born or of foreign parentage. Panama is served by regular steamers to San Francisco, Yokohama and other Pacific ports. The city

1 The state of Panama, with boundaries nearly corresponding to those of the present republic, and including the province of Panama and other provinces, was created in 1855 by legislative enactment.

is built on a rocky peninsula jutting out to the east, near the mouth of the Rio Grande and at the foot of Mt Ancon (360 ft.). The harbour is good and is enclosed at the south by several rugged islands, the largest being Perico and Flamenco (belonging to the United States) and Taboga (391 ft.), which is a place of country residence for wealthy citizens. The main streets run north and south and are cut by the Avenida Central; nearly all the streets are narrow and crooked. The principal squares are Cathedral, Santa Ana, Bolivar and Lesseps. The city proper is almost entirely enclosed by the remains of a great granite wall (built in 1673, when the new city was established), on the top of which on the side facing the sea is Las Bovedas promenade. The public buildings include the cathedral (1750), the government palace, the municipal palace, the episcopal palace, the church of Santa Ana, a national theatre, a school of arts and trades, a foreign hospital, the former administration building of the Canal Company, Santo Tomas Hospital, the house of Punta Mala and various asylums. The houses are mostly of stone, with red tile roofs, two or three storeys high, built in the Spanish style around central patios, or courts, and with balconies projecting far over the narrow streets; in such houses the lowest floor is often rented to a poorer family, the upper rooms being used as storehouses and granaries. The streets are lighted with electricity; and there are electric street railways and telephones in the city. The water supply and drainage systems were introduced by the United States government, which controls the sanitation of the city, but has no other jurisdiction over it. Two miles inland is Ancon, in the Canal Zone, in which are the hospitals of the Isthmian Canal Commission and the largest hotel on the isthmus. The city of Panama was formerly a stronghold of yellow fever and malaria, which American sanitary measures have practically eradicated. Panama has had an important trade: its imports, about twice as valuable as its exports, include cotton goods, haberdashery, coal, flour, silk goods and rice; the most valuable exports are gold, rubber, mother of pearl and cocoabolo wood. Balboa (3 m. west of the city, connected with it by railway, and formerly called La Boca), the port of Panama and the actual terminus of the canal, is in the Canal Zone and is a port under the jurisdiction of the United States, the commercial future of Panama is dependent upon American tariffs and the degree to which Panama and Balboa may be identified. At Balboa there are three warehouses on the shore, and a wharf 1000 ft. long, but their capacity is so insufficient that lighters are still necessary. In the city there is one small dock which can be used only at full tide. Small vessels may coal at Naos, an island in the Gulf of Panama, which is owned by the United States. Soap and chocolate are manufactured. Founded in 1510 by Pedro Arias de Avila, Panama is the oldest European town on the mainland of America. In the 16th century the city was the strongest Spanish fortress in the New World, excepting Cartagena, and gold and silver were brought hither by ship from Peru and were carried across the Isthmus to Characas; but as Spain's fleets even in the Pacific were more and more often attacked in the 17th century, Panama became less important, though it was still the chief Spanish port on the Pacific. In 1671 the city was destroyed by Henry Morgan, the buccaneer; it was rebuilt in 1673 by Alfonzo Mercado de Villacorta about five miles west of the old site and nearer the roadstead. The city has often been visited by earthquakes. In the city is the museum and the public library.

**PANAMA CANAL.** When he crossed the Atlantic, the object Columbus had in view was to find a western passage from Europe to Cathay. It was with the greatest reluctance, and only after a generation of unremitting toil that the explorers who succeeded him became convinced that the American continent was continuous, and formed a barrier of enormous extent to the passage of vessels. The question of cutting a canal through this barrier at some suitable point was immediately raised. In 1550 the Portuguese navigator Antonio Galvao published a book to demonstrate that a canal could be cut at Tehuantepec,
Nicaragua, Panama or Darien, and in 1551 the Spanish historian F. L. de Gomara submitted a memorial to Philip II urging in forcible language that the work be undertaken without delay. But the project was opposed by the Spanish Government, who had now concluded that a monopoly of communication with their possessions in the New World was of more importance than a passage by sea to Cathay. It even discouraged the improvement of the communications by land. To seek or make known any better route than the one from Porto Bello to Panama was forbidden under penalty of death. For more than two centuries no serious steps were taken towards the construction of the canal, if exception be made of William Paterson's disastrous Darien scheme in 1698. In 1771 the Spanish government, having changed its policy, ordered a survey for a canal at Tehuantepec, and finding that line impracticable, ordered surveys in 1779 at Nicaragua, but political disturbances in Europe soon prevented further action. In 1808 the isthmus was examined by Alexander von Humboldt, who pointed out the lines which he considered worthy of study. After the Central American republics acquired their independence in 1821, there was a decided increase of interest in the canal question. In 1825 the Republic of the Centre had received applications for concessions from citizens of Great Britain, and also from citizens of the United States, made offers to the United States for aid in constructing a canal, but they resulted in nothing. In 1830 a concession was granted to a Dutch corporation under the special patronage of the king of the Netherlands to construct a canal through Nicaragua, but the revolution and the separation of Belgium from Holland followed, and the scheme fell through. Subsequently numerous concessions were granted to citizens of the United States, France and Belgium, both for the Nicaragua and the Panama lines, but with the exception of the concession of 1878 for Panama and that of 1887 for Nicaragua, no work of construction was done under any of them.

Knowledge of the topography of the isthmus was extremely vague until the great increase of travel due to the discovery of gold in California in 1848 rendered improved communications a necessity. A railroad at Panama and a canal at Nicaragua were both projected. Instrumental surveys for the former in 1849, and for the latter in 1850, were made by American engineers, and, with some small exceptions, were the first accurate surveys made up to that time. The work done resulted in geographical knowledge sufficient to eliminate from consideration all but the following routes: (1) Nicaragua; (2) Panama; (3) San Blas; (4) Caledonia Bay; (5) Darien; (6) Atrato river, of which last there were four variants, the Tuyora, the Trunado, the Napipi and the Bojaya. In 1866, in answer to an inquiry from Congress, Admiral Charles H. Davis, U.S. Navy, reported that "there does not exist in the libraries of the world the means of determining even approximately the most practicable route for a ship canal across the American isthmus." To clear up the subject, the United States government sent out, between 1870 and 1875, a series of expeditions under officers of the navy, by whom all of the above routes were examined. The result was to show that the only lines by which a tunnel could be avoided were the Panama and the Nicaragua lines; and in 1876 a joint government resolution declared that the Nicaragua route possessed greater advantages and offered fewer difficulties than any other. At Panama the isthmus is narrower than at any other point except San Blas, its width in a straight line being only 35 m. and the height of the continental divide is only 300 ft., which is higher than the Nicaragua summit, but less than half the height on any other route. At Nicaragua the distance is greater, being about 156 m. in a straight line, but more than one third is covered by Lake Nicaragua, a sheet of fresh water with an area of about 3000 sq. m. and a maximum depth of over 200 ft., the surface being about 105 ft. above sea-level. Lake Nicaragua is connected with the Atlantic by a navigable river, the San Juan, and is separated from the Pacific by the continental divide, which is about 160 ft. above sea-level. At Panama only a canal with locks is feasible, but at Panama a sea-level canal is a physical possibility.

By the Clayton-Bulwer Treaty of 1850 with Great Britain, by the treaty of 1846 with New Granada (Colombia), Article XXXV., and by the treaty of 1867 with Nicaragua, Article XV., the United States guaranteed that the projected canal, whether the Panama or the Nicaraguan, should be neutral, and, furthermore, that it be used and enjoyed upon equal terms by the citizens of both countries in each case. A modification of the Clayton-Bulwer Treaty being necessary to enable the United States to build the canal, a treaty making such modifications, but preserving the principle of neutrality, known as the Hay-Pauncefote Treaty, was negotiated with Great Britain in 1900; it was amended by the United States Senate, and the amendments not proving acceptable to Great Britain, the treaty lapsed in March 1901. A new treaty, however, was negotiated in the autumn, and accepted in December by the U.S. Senate. The completion of the Suez Canal in 1869, and its subsequent success as a commercial enterprise, drew attention more forcibly than ever to the American isthmus. In 1876 an association entitled "Société Civile Internationale du Canal Interoceanique" was organized in Paris to make surveys and explorations for a canal. An expedition under the direction of Lieut. L. N. B. Wyse, an officer of the French navy, was sent to the isthmus to examine the Panama line. In May 1878 Lieut. Wyse, in the name of the association, obtained a concession from the Colombian government, commonly known as the Wyse Concession. This is the concession under which work upon the Panama Canal has been prosecuted. Its first holders did no work of construction.

In May 1879 an International Congress composed of 135 delegates from various nations—some from Great Britain, United States and Germany, but the majority from France—was convened in Paris under the auspices of Ferdinand de Lesseps, to consider the best situation for, and the plan of, a canal. After a session of two weeks the Congress decided that the canal should be at the sea-level, and at Panama. Immediately after the adjournment of the Congress the Panama Canal Company was organized under a general law of France, with Lesseps as president. The company purchased the Wyse Concession at the price of 10,000,000 francs. An attempt to float this company in August 1879 failed, but a second attempt, made in December 1880, was fully successful, 6,000,000 shares of 500 francs each being sold. The next two years were devoted to surveys and examinations and preliminary work upon the canal. The plan adopted was for a sea-level canal having a depth of 29 ft. and bottom width of 72 ft., involving excavation estimated at 157,000,000, cub. yds. The cost was estimated by Lesseps in 1880 at 65,000,000 francs, and the time required at eight years. The terminus on the Atlantic side was fixed by the anchorage at Colon, and that on the Pacific side by the anchorage at Panama. Leaving Colon, the canal was to pass through low ground by a direct line for a distance of 6 m. to Gatun, where it intersected the valley of the Chagres river; pass up that valley for a distance of 21 m. to Obiso, where it left the Chagres and ascended the valley of a tributary, the Cumacho; cut through the watershed at Culebra, and thence descend by the valley of the Rio Grande to the Pacific, a length from deep water in the Atlantic to deep water in the Pacific of about 47 m. It was laid out in such a way as to give easy curvature everywhere; the sharpest curve, of which there was but one, had a radius of 6200 ft., four others had a radius of 8200 ft., and all others had a radius of 9800 ft. or more. To secure this it was necessary to select a point for crossing the watershed where the height was somewhat greater than that of the lowest pass. The line was essentially the same as that followed by the Panama railroad, the concession for which granted a monopoly of that route; the Wyse Concession, therefore, was applicable only upon condition that the canal company could come to an amicable agreement with the railroad company.

The principal difficulties to be encountered in carrying out this plan consisted in the enormous dimensions of the cut to be made at Culebra, and in the control of the Chagres river, the valley of which
is occupied by the canal for a large part of its length. This stream is of torrential character, its discharge varying from a minimum of about 350 cub. ft. to a maximum of over 100,000 cub. ft. per second. It rose at Gamba on the 1st of December 1890, 13 ft. in twelve hours; then subsided, and was drawn out from 1,500 cub. ft. per second at the same time; and similar violent changes are not uncommon. To admit a stream of this character to the canal would be an intolerable nuisance to navigation unless space could be provided for its migration. For a canal with locks the problem is simple, but for a sea-level canal the problem is much more difficult, and no satisfactory solution of the question was ever reached under the Lesseps plan. The work of this plan continued until the latter part of 1887, but the management being characterized by a degree of extravagance and corruption rarely if ever equaled in the history of the world. By that time it had become evident that the canal could not be completed as planned, at a sea-level with the resources of time and money then available. The plan was accordingly changed to one including locks, and work was pushed on with vigour until 1889, when the company, becoming bankrupt, was dissolved by a judgment of the Tribunal Civil de la Seine, dated the 4th of February 1889, a liquidator being appointed by the court to take charge of its affairs. One of the more important duties assigned to this official was to keep the property together and the concession alive, with a view to the formation of a new company for the completion of the canal. He gradually reduced the number of men employed, and finally suspended the work on the 15th of May 1889. He then proceeded to satisfy himself that the canal project was feasible, a question about which the results of the commission’s investigations were grave doubts, and that the canal could be completed at a sea-level with the aid of French and foreign engineers. This commission reported on the 9th of May 1890 that a canal with locks, for which they submitted a plan, could be built in eight years at a cost of $800,000,000 for the French share; $300,000,000 for the United States share; $150,000,000 for the Mexican share; and $50,000,000 for the British share, to include administration and financing. They reported that the plant in hand was in good condition and would probably suffice for finishing the canal, and they estimated the value of the work done by the plant in hand at 450,000,000 francs.

The time within which the canal was to be completed under the Panama Concession having nearly expired, the liquidator sought and obtained from the Colombian government an extension of ten years. This was done on the 23rd of December 1894, the first of 1895, and the date fixed for completion of the canal being the 31st of October 1910. For each of these extensions the Colombian government exacted heavy subsidies.

The liquidator finally secured the organization of a new company on the 20th of October 1894. The new company was regularly organized under French law, and was recognized by the Colombian government. It was technically a private corporation, but the great number of persons interested in the securities of the old company, and the special legislation of the French Chambers, gave it a semi-national character. By the law of the 8th of June 1888, all machinery and tools used in the work must be of French manufacture, and raw material must be of French origin. Its capital stock consisted of 650,000 shares of 100 francs each, of which 50,000 shares belonged to Colombia. It succeeded to all the rights of the old company in the concessions, works, lands, buildings, plant, maps, drawings, &c., and shares of the Panama railroad. For the contingency that the canal should not be completed, special conditions were made as to the Panama railroad shares. The new company had the privilege of purchasing for 20,000,000 francs, or one-half the net annual profits of the road. The Panama railroad retained its separate organization as an American corporation.

Immediately after its organization in 1894 the new company took possession of the property (except the Panama railroad shares, which were held in trust for its benefit), and proceeded to make a new study of the entire subject of the canal in its engineering and commercial aspects. It resumed the work of excavation, with a moderate number of men sufficient to supply with the terms of the concession, in a part of the line—the Emperor and Culebra cuts—where such excavation must contribute to the enterprise if completed under any plan. By the middle of 1895, about 2000 men were employed, and the canal was opened continuously from 20 to 30 days into the sea. The number of workmen varying between 2000 and 3000. The amount of material excavated to the end of 1898 was about $850,000,000. The amount expended to the 30th of December was about $15,000,000,000, besides about $6,500,000 francs advanced to the Panama Railroad Company for building a pier at La Boca.

The charter provided for the appointment by the company and the government of a board of superintendents, to report upon the work done and the conclusions to be drawn therefrom, this report to be rendered when the amounts expended by the new company should have reached about one-half its capital. The plan was that an extraordinary meeting of the stockholders was then to be held to determine whether or not the canal should be completed, and to provide ways and means. The time for this report and special meeting arrived in 1898. In the meanwhile the company had called to its aid a technical committee composed of fourteen engineers, European and American, some of them among the most eminent in their profession. After a study of all the data available, and of such additional surveys as were required, the committee, at a meeting held in Paris, rendered an elaborate report dated the 16th of November 1898. This report was referred to the statutory commission of five, who reported in 1899 that the canal could be built according to that project within the limits of time and money estimated. The special measures necessary for locks, for their sinking, for their scheme of excavation, and for the methods of work, were settled at the annual meeting of the 30th of December 1899. It is understood that the liquidator (who held about one-fourth the stock) refused to take part in it, and that no conclusions were reached as to the expenditure of the sum required to complete the canal, and the means.

The engineering questions had been solved to the satisfaction of the company, but the financial questions had been made extremely difficult, if not insoluble, by the appearance of the United States government in the case as a probable builder of an isthmian canal. The company continued to conduct its operations in a provisional way, without appealing to the public for capital.

The plan adopted by the company involved two levels above the sea-level, but in the meantime the question of the Boano, to be reached from the Atlantic by a flight of two locks, and the other, the summit-level, to be reached by another flight of two locks from the preceding. The summit-level was to have its surface at high water 102 ft. above the sea. The proposed canal would have a new width within certain specified parts. Its general plan was the same as that adopted by the old company. The locks were to be double, or twin locks, the chambers to have a serviceable length in the sea, from 731 ft. to 737 ft., and 138 ft. to 140 ft. in width, with lifts varying from 20 to 33 ft., according to station and stage of water. The time required to build the canal was estimated at ten years, and its cost at $25,000,000 francs for the works, not including administration and financing.

The occupation of the Panama route by Europeans, and the prospect of a canal there under foreign control, was not a pleasing spectacle to the people of the United States. The favour with which the Nicaragua Scheme.

Nicaragua.

route had been considered since 1876 began to assume a partisan character, and the movement to construct a canal across the Nicarauguian isthmus, in accordance with a treaty, known as the Frelinghuysen-Zarala Treaty, was negotiated with Nicaragua, by the terms of which the United States Government was to build the canal without cost to Nicaragua, and after completion it was to be owned and managed jointly by the two governments. The treaty was submitted to the United States Senate, and in the vote for ratification, on the 29th of January 1885, received thirty-two votes in its favour against twenty-three. The necessary two-thirds vote not having been obtained, the treaty was not ratified, and a change of administration occurred soon afterwards, it was withdrawn from further consideration. This failure led to the formation in New York by private citizens in 1886 of the Nicaragua Canal Association, for the purpose of obtaining the necessary concessions, making surveys, laying out the route, and organizing such corporations as should be required to construct the canal. They obtained a concession from Nicaragua in April 1887, and one from Costa Rica in August 1888, and sent parties to survey the canal. An act for the incorporation of an association to
be known as the Maritime Canal Company of Nicaragua passed Congress and was approved on the 20th of February 1889, and on the 4th of May 1889 the company was organized. It took over the concessions and, acting through a construction company, began work upon the canal in June 1889. Operations upon a moderate scale and mainly of a preliminary character were continued until 1893, when the financial disturbances of that period drove the construction company into bankruptcy and compelled a suspension of the work. It has not since been resumed. At that time the canal had been excavated to a depth of 17 ft. and a width of 280 ft. for a distance of about 3000 ft. inland from Greytown; the canal line had been cleared of timber for a distance of about 20 m.; a railroad had been constructed for a distance of about 11 m. inland from Greytown; a pier had been built for the improvement of Greytown harbour and other works undertaken. In all, about $4,500,000 had been expended.

Congress continued to take an interest in the enterprise, and in 1895 provided for a board of engineers to inquire into the possibility, permanence, and cost of the canal as projected by the Maritime Canal Company. The report of this board, dated August 26, 1895, recommended the rejection of the plans and estimates of the company, and led to the appointment in 1897 of another board, to make additional surveys and examinations, and to prepare new plans and estimates. The second board recommended some radical changes in the plans, and especially in the estimates, but its report was not completed when the revival of the Panama scheme attracted the attention of Congress, and led to the creation in 1898 of the Isthmian Canal Commission. In the meanwhile the property of the Maritime Canal Company has become nearly worthless through decay, and its concession has been declared forfeited by the Nicaraguan government.

The interest of the United States in an isthmian canal was not essentially different from that of other maritime nations that, down to the middle of the 19th century, assumed that it would be their duty to build the canal, but it assumed a great strength when California was acquired, and it has steadily grown in importance as the Pacific States has developed. In 1848 and again in 1884, treaties were negotiated with Nicaragua, giving the United States the right to build the canal, but in neither case was the treaty ratified. The Spanish War of 1898 gave a tremendous impetus to popular interest in the matter, and it seemed an article of the national faith that the canal must be built, and, furthermore, that it must be under American control. To the American people the canal appears to be not merely a business enterprise from which a direct revenue is to be obtained, but rather a means of uniting and strengthening their national political interests, and of developing their industries, particularly in the Pacific States; in short, a means essential to their national growth. The Isthmian Canal Commission created by Congress in 1899 to examine all practicable routes, and to report which was the most practicable and most feasible for a canal under the control, management and ownership of the United States, reported that there was no route which did not present greater disadvantages than those of Panama, and recommended the adoption of the Panama route. If the Panama route be adopted, the question of a new location of the Panama Canal at Lake Gatun a depth of 35 ft. and a bottom width of 150 ft.; the locks to be double, the lock chambers to have a length of 740 ft., width 84 ft. and depth 35 ft. in the clear. The cost of a canal with these dimensions, built essentially upon the French plans, was estimated at $176,375,828. A plan, however, was recommended for the height of the dam to be increased about 20 ft., the level of Lake Bohio raised by that amount, the lake made the summit-level, and the Alajuela dam omitted. The cost upon this plan was estimated at $143,971,127.

According to the plan recommended by the Commission for Nicaragua the line began at Greytown on the Caribbean Sea, where an artificial harbor was to be constructed and follow the valley of the San Juan for 100 m. to Lake Nicaragua; thence across the lake about 70 m. to the mouth of Las Lajas river; then up the valley of that stream through the watershed, and down the valley of the Rio Grande, 17 m. to Brio on the Pacific, where also an artificial harbor was to be constructed. The distance from ocean to ocean is 187 m. Almost midway between the lake and the Caribbean the San Juan receives its most important affluent, the San Carlos, and undergoes a radical change in character. Above the junction it is a clear water stream, capable of improvement by locks and dams. Below, it is choked with sand, and not available for slack-water navigation. A dam across the San Juan above the mouth of the San Carlos was to maintain the water of the river above that point on a level with the lake. The line of the canal occupied essentially the bed of the river from the lake to the dam; from the dam to the Caribbean it followed the left bank of the river, keeping at a safe distance from it, and occasionally cutting through a high projecting ridge. The lake and the river above the dam constitute the summit-level, which would have varied in height at different seasons from 104 to 110 ft. above mean sea-level. It would have been reached from the Caribbean side by five locks, the first having a lift of 56 ft., and the others a uniform lift of 56 ft. each, making a total lift of 110 ft. from low tide in the Caribbean to high tide in the Pacific. On the other side the San Carlos, which has been adopted by four locks having a uniform lift of 28 ft. each, making a total canal lift of 114 ft. from low tide in the Pacific to high tide in the lake. The time required to build the canal was estimated at ten years, and its cost at $200,000,000.

The report of the commission, transmitted to Congress at the end of 1900, ended thus:—

The Panama Canal, after completion, would be shorter, have fewer locks and less curvature than the Nicaragua Canal. The measure of these advantages is the time required for a vessel to pass through, which is estimated for an average ship at 12 hours for Panama and 33 hours for Nicaragua. On the other hand, the distance from San Francisco to New York is 777 m., to New Orleans 575 m. and to Liverpool 856 m. greater via Panama than via Nicaragua. The time required to pass over these distances with the same vessels is 42 days by way of Panama, and 45 days by way of Nicaragua. The time, therefore, for a vessel to pass through the canals, the Nicaragua line after completion, would be somewhat the more advantageous of the two to the United States, notwithstanding the greater cost of maintaining the longer line.

The government of Colombia, in which lies the Panama Canal, has granted an exclusive concession, which still has many years to run. It is not free to grant the necessary rights to the United States, except upon the condition that it must be turned over to the New Panama Canal Company. The Commission believes that such agreement is impracticable. So far as can be ascertained, the company is not willing to sell its franchise, but will allow the United States to become the owner of part of its stock. The Commission considers such an arrangement inadmissible. The Governments of Nicaragua and Costa Rica, on the other hand, are untrammeled by concessions, and are free to grant to the United States such privileges as may be mutually agreed upon.

In view of all the facts and, particularly in view of all the difficulties of obtaining the necessary rights, privileges and franchises on the Panama route, and assuming that Nicaragua and Costa Rica recognize the value of the canal to themselves, and are prepared to grant concessions on terms which are reasonable and acceptable to the United States, the Commission is of the opinion that the most practicable and feasible route for an isthmian canal to the Pacific is by Panama, and that the ownership and operation of the United States, is that known as the Nicaragua route.

This report caused the New Panama Canal Company to view the question of selling its property in a new light, and in the spring of 1901 it obtained permission from the Colombian government to dispose of it to the United States. It showed itself, however, somewhat reluctant to name a price to the Canal Commission, and it was not until January 1902 that it definitely offered to accept $40,000,000. In consequence of this offer, the commission in a supplementary report issued on the 18th of January 1902 reversed the conclusion it had stated in its main report, and advised the adoption of the Panama route, with purchase of the works, &c., of the French company. A few days previous to this report the Hepburn bill authorizing the Nicaragua canal at a cost of $180,000,000, had been carried in the House of Representatives by a large majority, but when it reached the Senate an amendment—the so-called Spooner bill—was moved and finally became law on the 28th of June 1902. This authorized the president to acquire
all the property of the Panama Canal Company, including not less than 68,869 shares of the Panama Railroad Company, for a consideration exceeding $40,000,000, and to obtain from Colombia perpetual control of a strip of land 6 m. wide, while if he failed to come to terms with the company and with Colombia in a reasonable time and on reasonable terms, he was by treaty to obtain from Costa Rica and Nicaragua the territory necessary for the Nicaragua canal.

Negotiations were forthwith opened with Colombia, and ultimately a treaty (the Hay-Herran treaty) was signed in January 1903. The Colombian Senate, however, refused ratification, and it seemed as if the Panama scheme would have to be abandoned when the complexion of affairs was changed by Panama revolting from Colombia and declaring itself independent in November 1903. Within a month the new republic, by the Hay-Bunau-Varilla treaty, granted the United States the use, occupation and control of a strip of land 10 m. wide for the purposes of the canal. A few days after the ratification of this treaty by the United States Senate in February 1904—the concession of the French company having been purchased—a commission was appointed to undertake the organization and management of the enterprise, and in June Mr J. F. Wallace was chosen chief engineer. Work was begun without delay, but the commission's methods of administration and control soon proved unsatisfactory, and in April 1905 it was reorganized, three of its members being constituted an executive committee which was to be at Panama continuously. Shortly afterwards, at the end of June, Mr Wallace resigned his position as chief engineer and was succeeded by Mr John F. Stevens.

In connexion with the reorganization of the commission a board of consulting engineers, five being nominated by European governments, was appointed in June 1905 to consider the question, which so far had not been settled, whether the canal should be made at sea-level, without locks (at least except for regulation locks at or near the Pacific terminus), or should rise to some elevation above sea-level, with locks. The board reported in January 1906. The majority (eight members out of thirteen) declared in favour of a sea-level canal as the only plan "giving reasonable assurance of safe and uninterrupted navigation"; and they considered that such a canal could be constructed in twelve or thirteen years' time, that the cost would be less than $350,000,000, and that it would endure for all time. The minority recommended a lock canal, rising to an elevation of 83 ft. above mean sea-level, on the grounds that it would cost about $100,000,000 less than the proposed sea-level canal, that it could be built in much less time, that it would afford a better navigation, that it would be adequate for all its uses for a longer time, and that it could be enlarged if need should arise with greater facility and less cost. The chief engineer, Mr Stevens, also favoured the lock or high-level scheme for the reasons, among others, that it would provide as safe and a quicker passage for ships, and therefore would be of greater capacity; that it would provide, beyond question, the best solution of the vital problem how safely to care for the flood waters of the Chagres and other streams, that provision was made for enlarging its capacity to almost any extent at very much less expense of time and money, than could be provided for by any sea-level plan; that its cost of operation, maintenance and fixed charges would be very much less than those of any sea-level canal; and that the time and cost of its construction would be not more than one-half that of a canal of the sea-level type. These conflicting reports were then submitted to the Isthmian Canal Commission for consideration, with the result that on the 5th of February, it reported, one member only dissenting, in favour of the lock canal recommended by the minority of the board of consulting engineers. Finally this plan was adopted by Congress in June 1906. Later in the same year tenders were invited from contractors who were prepared to undertake the construction of the canal. These were opened in January 1907, but none of them was regarded as entirely satisfactory,
President Roosevelt decided that it would be best for the government to continue the work, which was placed under the immediate control of the U.S.A. Corps of Engineers. At the same time the Isthmian Canal Commission was reorganized, Major G. W. Goethals, of the Corps of Engineers, becoming the chief and chairman, in succession to Mr. J. F. Stevens who, after succeeding Mr. T. F. Shonts as chairman, himself resigned on the 1st of April.

The following are the leading particulars of the canal, the course of which is shown on the accompanying map. The length from deep water in the Atlantic to deep water in the Pacific will be about 50 m., or, since the distance from deep water to the shore-line is about 4½ m. in Limon Bay and about 5 m. at Panama, approximately 46½ m. above sea-level. The waterway, from 82 and 87 ft. above sea-level, will extend for 3½ m. from a large earth dam at Gatun to a smaller one at Pedro Miguel, and is to be reached by a flight of 3 locks at the former point. The Gatun dam will be 7200 ft. long along the crest including the spillway, will have a maximum width at its base of 2000 ft., and will be uniformly 100 ft. wide at its top, which will rise 115 ft. above sea-level. The lake (Lake Gatun) enclosed by these dams will be 1641 sq. m. in area, and will constitute a reservoir for receiving the flood of the Chagres and other rivers as well as for supplying water for lockage. A smaller lake (Lake Miraflores), with a surface elevation of 55 ft., and an area of about 2 sq. m. will extend from a lock at Pedro Miguel to the sea. Granada, lying on the west of a con- crete dam with spillway on the east, and the canal is to descend to sea-level by a flight of two locks. All the locks are to be in duplicate, each being 110 ft. wide and 90 ft. long in the United States, will be 1000 ft. or more in width for a distance of nearly 16 m. to San Pablo. Thence it narrows first to 800 ft., and then for a short distance to 700 ft., for 3½ m. to mile 27 near Juan Grande, and to 500 ft. for 4½ m. from Juan Grande to Obispo. From Obispo to the mouth of the Chagres River, through Pedro Miguel lock, it will be only 300 ft. wide, but will widen again to 500 ft. through Miraflores, 1½ m. long, to Miraflores locks, the total length of which including approaches will be nearly a mile, and will maintain the same width of 500 ft. to a depth of 8 m. to deep water in the Pacific. The minimum bottom width of the canal will thus be 500 ft., the average being 649 ft., although the minimum depth will be 41 ft.

In 1901 it was estimated that the construction of the canal would be completed by the 1st of January 1915, and that the total cost to the United States would not exceed $35,750,000 including water, $250,000 paid to the French Canal Company and the Republic of Panama, $57,000 for land, and $750,000 for local labor, as well as $1,000,000 for local labor, as well as $1,000,000 as a special charge for the maintenance of the canal. The last was one of the most necessary expenditures of all, since without it the work would have greatly retarded the work or perhaps prevented it altogether.

Several years later, the Panama Canal (Washington, 1906); Report of the Board of Consulting Engineers for the Panama Canal (Washington, 1906); Annual Reports of the Isthmian Canal Commission (Washington); Vaughan Cornish, The Panama Canal and its Makers (London, 1909).

PAN-AMERICAN CONFERENCES. At intervals delegates from the independent countries of North, Central and South America have met in the interests of peace and for the improvement of commercial relations and for the discussion of various other matters of common interest. A movement for some form of union among the Spanish colonies of Central and South America was inaugurated by Simon Bolivar while those colonies were still fighting for independence from Spain, and in 1832 the United States, which in May 1822 had recognized their independence and in December 1823, had promulgated the Monroe Doctrine, was invited by the governments of Mexico and Colombia to send commissioners to conference in Panama the following year. Henry Clay, the secretary of state, hoped the congress might be the means of establishing a league of American republics under the hegemony of the United States, and under his influence President J. Q. Adams accepted the invitation, giving notice however that the commissioners from the United States would not be authorized to act in any way inconsistent with the neutral attitude of their country toward Spain and her revolting colonies. The principal objects of the Spanish-Americans in calling the congress were, in fact, to form a league of states to resist Spain or any other European power that might attempt to interfere in America and to consider the expediency of freeing Cuba and Porto Rico from Spanish rule; but in his message to the Senate asking that body to approve his appointment of commissioners Adams declared that his object in appointing them was to manifest a friendly interest in the young republics, give them some advice, promote commercial reciprocity, obtain from the congress satisfactory definitions of the terms “blockade” and “neutral rights” and encourage religious liberty. In the Senate the proposed mission provoked a spirited attack on the administration. Some senators feared that it might be the means of dragging the United States into entangling alliances; others charged that the President had construed the Monroe Doctrine as a pledge to the southern republics that if the powers of Europe joined Spain against them the United States would come to their assistance with arms and men; and a few from the slaveholding states wished to have nothing to do with the republics because they proposed to make Cuba and Porto Rico independent and liberate the slaves on those islands. The Senate finally, after a delay of more than ten weeks, confirmed the appointments.

There was further delay in the House of Representatives, which was asked to make an appropriation for the mission; one of the members of the House, Richard J. Oglesby, died on the way (at Cartagena, July 24), and when the other, John Sergeant (1779-1852), reached Panama the congress, consisting of representatives from Colombia, Guatemala, Mexico and Peru, had met (June 22), concluded and signed a "treaty of union, league and perpetual confederation" and adjourned to meet again at Tacubaya, near the City of Mexico. The governments of Guatemala, Mexico and Peru refused to ratify the treaty and the Panama congress or conference was a failure. The meeting at Tacubaya was never held.

Mexico proposed another conference in 1831, and repeated the proposal in 1838, 1839 and 1840, but each time without result. In December 1847, while Mexico and the United States were at war, a conference of representatives from Bolivia, Chile, Ecuador, New Granada and Peru met at Lima, gave the other American republics the privilege of joining in its deliberations or becoming parties to its agreements, continued to deliberate until the 1st of March 1848, and concluded a treaty of confederation, a treaty of commerce and navigation, a provisional treaty and a convention on the rights of the rivers that flowed through the territory of the co-signers; a convention New Granada its work was rejected. Representatives from Peru, Chile and Ecuador met at Santiago in September 1856 and signed the "Continental Treaty" designed to promote the union of the Latin-American republics, but expressing hostility toward the United States as a consequence of the filibustering expeditions of William Walker (1824-1860); it never became effective. In response to an invitation from the government of Peru to each of the Latin-American countries, representatives from Guatemala, Colombia, Venezuela, Ecuador, Peru, Bolivia and Argentina met in a conference at Lima in November 1864 to form a "Union". Colombia was opposed to extending the invitation to the United States lest that country should "embarrass the action of the Congress"; the conference itself accomplished little. In 1877-1878, jurists from Peru, Bolivia, Cuba, Chile, Ecuador, Honduras, Argentina, Venezuela and Costa Rica met at Lima and concluded a treaty of extradition and a treaty on private international law, and Uruguay and Guatemala agreed to adhere to them. War among the South American states was imminent, and a convention was called by the government of Colombia to meet at Panama in September 1883 and of another which had been called by the government of the United States to meet at Washington in November 1882. In 1888-1886 jurists from Argentina, Bolivia, Brazil, Chile, Paraguay, Peru and Uruguay met at Montevideo and concluded treaties on international civil law, international commercial law, international penal law, international law of procedure, literary and artistic property, trade-marks and patents, several of which were subsequently ratified by the South American countries.
In May 1888 the Congress of the United States had passed an Act authorizing the President to invite the several Latin-American governments to a conference in Washington to consider measures for preserving the peace, the formation of a customs union, the establishment of better communication between ports, the adoption of a common silver coin, a uniform system of weights, measures, patents-rights, copyrights and trade-marks, the subject of sanitation of ships and quarantine, &c. All the governments except Santo Domingo accepted the invitation and this conference is commonly known as the first Pan-American Conference. It met on the 2nd of October 1889, was presided over by James G. Blaine, the American secretary of state, who had been instrumental in having the conference called, and continued its sessions until the 19th of April 1890. A majority of its members voted for compulsory arbitration, and recommendations were made relating to reciprocity treaties, customs regulations, port duties, the free navigation of American rivers, sanitary regulations, a monetary union, weights and measures, patents and trade-marks, an international American bank, an intercontinental railway, the extradition of criminals, and several other matters. Nothing came of its recommendations, however, except the establishment in Washington of an International Bureau of American Republics for the collection and publication of information relating to the commerce, products, laws and customs of the countries represented. At the suggestion of President McKinley the government of Mexico called the second Pan-American Conference to meet at the City of Mexico on the 22nd of October 1901. There was a full representation and the sessions were continued until the 31st of January 1902. The chief subject of discussion was arbitration, and after much wrangling between those who insisted upon compulsory arbitration and those opposed to it a majority of the delegations signed a project whereby their countries should become parties to the Hague conventions of 1899, which provide for voluntary arbitration. At the conclusion of the conference several of the members of the conference recommended a project for a treaty providing for compulsory arbitration. The conference also approved a project for a treaty whereby controversies arising from pecuniary claims of individuals or of one country against the government of another should be submitted to the arbitration court established by the Hague convention. The conference ratified a resolution of the first conference recommending the construction of complementary lines of the proposed Pan-American railway.

At this conference, too, the International Bureau of American Republics was organized under a governing board of diplomats with the secretary of state of the United States as chairman; it was directed to publish a monthly bulletin, and in several other respects was a more important institution. Its governing board was directed to arrange for the third Pan-American Conference, and this body was in session at Rio de Janeiro from the 21st of July to the 26th of August 1906. Delegates attended from the United States, Argentina, Bolivia, Brazil, Chile, Colombia, Costa Rica, Cuba, San Domingo, Ecuador, Guatemala, Honduras, Mexico, Nicaragua, Panama, Paraguay, Peru, Surinam, Uruguay, and Venezuela, were represented. The secretary of state of the United States, Elihu Root, though not a delegate, addressed the conference. The subjects considered were much the same as those at the two preceding conferences. With respect to arbitration this conference passed a resolution that the delegates from the American republics to the second conference at the Hague be instructed to endeavour to secure there "the celebration of a general arbitration convention so effective and definite that, meriting the approval of the civilized world, it shall be accepted and put in force by every nation." With respect to copyrights, patents and trademarks this conference re-affirmed the conventions of the second conference, with some modifications; with respect to naturalization it recommended that whenever a native of one country who has been naturalized in another again takes up his residence in his native country without intending to return to his adopted country he should be considered as having resumed his original citizenship; and with respect to the forcible collection of public debts to which the "Drago Doctrine" is opposed, the conference recommended that the Governments represented therein consider the point of inviting the Second Peace Conference at the Hague to consider the question of the compulsory collection of public debts, and, in general, means tending to diminish between nations conflicts having an exclusively pecuniary origin. The Fourth Conference met in Buenos Aires in July-August 1910, agreed to submit to arbitration such money claims as cannot be amicably settled by diplomacy, and renamed the Bureau the Bureau of Pan-American Union.

The first Pan-American scientific congress met at Santiago, Chile, on the 25th of December 1908 for the consideration of distinctly American problems. It continued in session until the 5th of January 1909, and resolved that a second congress for the same purpose should meet at Washington in 1912. See International American Conference, Reports and Recommendation (Washington, 1890), and especially the Historical Appendix.

**Panathenaea**, the oldest and most important of the Athenian festivals. It was originally a religious celebration, founded by Erechtheus (Erechtheus), in honour of Athena Polias, the patron goddess of the city. It is said that when Theseus united the whole land under one government he made the festival of the city-goddess common to the entire country, and changed the older name Athanaea to Panathenaea (Plutarch, Theseus, 24). The union (Synoecism) itself was celebrated by a distinct festival, called Synoecia or Synoecesia, which had no connexion with the Panathenaea. In addition to the religious rites there is said to have been a chariot race from the earliest times, in which Erechtheus himself won the prize. Considerable alterations were introduced into the proceedings by Peisistratus (q.v.) and his sons. It is probable that the distinction of Greater and Lesser Panathenaea dates from this period, the latter being a shorter and simpler festival held every year. Every fourth year the festival was celebrated with peculiar magnificence; gymnastic sports were added to the horse races; and there is little doubt that Peisistratus aimed at making the pentetic Panathenaea the great Ionian festival in rivalry to the Doric Olympia. The pentetic festival was celebrated in the third year of each Olympiad. The annual festival, probably held on the 28th and 29th of Hecatombaeon (about the middle of August), consisted solely of the sacrifices and rites proper to this season in the cult of Athena. One of these rites originally consisted in carrying a new peplos (the state robe of Athena) through the streets to the Acropolis to clothe the ancient carved image of the goddess, a ceremonial known in other cities and represented by the writer of the Iliad (vi. 87) as being in use at Troy; but it is probable that this rite was afterwards restricted to the great pentetic festival. The peplos was a costly, saffron-coloured garment, embroidered with scenes from the battle between the gods and giants, in which Athena had taken part. At least as early as the 3rd century B.C. the custom was introduced of spreading the peplos like a sail on the mast of a ship, which was rolled on a machine in the procession. Even the religious rites were celebrated with much greater splendour at the pentetic festival than at the other ceremonial processions. There was a great sacrifice; every colony and every subject state sent a deputation and sacrificial animals. On the great day of the feast there was a procession of the priests, the sacrificial assistants of every kind, the representatives of every part of the empire with their victims, of the cavalry, in short of the population of Attica and

---

1 So named from a note (1902) directed by Dr Don Louis Maria Drago, the Argentine minister of foreign affairs, to the Argentine diplomatic representative at Washington at the time of the difficulties of Venezuela incident to the collection of debts owed to that country by the United States.

2 The Bureau is supported by contributions, varying in amount according to population, of the twenty-one American republics, Andrew Carnegie contributed $75,000, and the various republics $250,000 for the erection of a permanent home for the Bureau in Washington. The Bureau has a library of some 15,000 volumes, and publishes numerous handbooks, pamphlets and maps, in addition to its monthly Bulletins. Its executive head is a director, chosen by the Governing Board.
great part of its dependencies. After the presentation of the peplus, the hecatomb was sacrificed. The subject of the frieze of the Parthenon is an idealized representation of this great procession.

The festival which had been beautified by Peisistratus was still more imposing under the rule of Pericles. He introduced a regular musical contest in place of the old recitations of the rhapsodes, which were an old standing accompaniment of the festival. This contest took place in the Odeum, originally built for this purpose by Pericles himself. The order of the agonae from this time onwards was—first the musical, then the gymnastic, then the equestrian contest. Many kinds of contest, such as the chariot race of the apobates (said to have been introduced by Erechtheus), which were not in use at Olympia, were practised in Athens. Apobates was the name given to the companion of the charioteer, who showed his skill by leaping out of the chariot and up again while the horses were going at full speed. There were in addition several minor contests: the Pyrrhic, or war dance, celebrating the victory of Athena over the giants; the Euandria, whereby a certain number of men, distinguished for height, strength and beauty, were chosen as representatives of the procession; the Teleomachia or torch-race; the Naumachia (Regatta), which took place on the last day of the festival. The proceedings were under the superintendence of ten athlaiotai, one from each tribe, the lesser Panathenae being managed by hieroepoi. In the musical contests, a golden crown was given as first prize; in the sports, a garland of leaves from the sacred olive trees of Athens, and vases filled with oil from the same. Many specimens of these Panathenaic vases have been found; on one side is the figure of Athena, on the other a design showing the nature of the competition in which they were given as prizes. The season of the festival was the 22th to the 29th of Hecatombaeon, and the great day was the 28th.

Purser in Smith's Dictionary of Antiquities (3rd ed., 1891); L. R. Farnell, Cults of the Greek States; also article ATHENA and works quoted.

PANCH MAHALS ( = Five Districts), a district of British India, in the northern division of Bombay. Area, 1,566 sq. m., pop. (1901), 261,020, showing a decrease of 17% in the decade, owing to famine. The administrative headquarters are at Godhra, pop. (1901), 20,915. Though including Champaran, the old Hindu capital of Gujarat, now a ruin, this tract has no history of its own. It became British territory as recently as 1861, by a transfer from Sindia; and it is the only district of Bombay proper that is administered on the non-regulation system, the collector being also political agent for Rewa Kantha. It consists of two separate parts, divided by the territory of a native state. The south-western portion is for the most part a level plain of rich soil; while the northern, although it comprises some fertile valleys, is generally rugged, undulating and barren, with but little cultivation. The mineral products comprise sandstone, granite and other kinds of building stone. Mining for manganese on a large scale has been begun by a European company, the Manganese Mining and Development Co., which has been most successful and is making a profit. Only recently has any attempt been made to conserve the extensive forest tracts, and consequently little timber of any size is to be found. The principal crops are maize, millets, rice, pulse and oilseeds; there are manufactures of lac bracelets and lacquered toys; the chief export is timber. Both portions of the district are crossed by the branch of the Bombay and Baroda railway from Anand, through Godhra and Dohad, to Ratlam; and a chord line, opened in 1903, runs from Godhra to Baroda city. The district suffered very severely from the famine of 1898-1900.

PANCREAS (Gr. παρεσ, all; κέφας, flesh), or sweetbread, in anatomy, the elongated, tongue-shaped, digestive gland, of a pinkish colour, which lies across the posterior wall of the abdomen about the level of the first lumbar vertebra behind, and of the transpyloric plane in front (see Anatomy: Superficial and Articulata). Its right end is only a little to the right of the mid line of the abdomen and is curved down, round the superior mesenteric vessels, into the form of a C. This hook-like right end is known as the head of the pancreas; and its curve is adapted to the concavity of the duodenum (see fig.). The first part of the straight limb is narrower from above downward than the rest and forms the neck. This part lies just in front of the beginning of the portal vein, just below the pyloric opening of the stomach and just above the superior mesenteric vessels.

The next three or four inches of the pancreas, to the left of the neck, form the body and this part lies in front of the left kidney and adrenal body, while it helps to form the posterior wall of the "stomach chamber" (see Alimentary Canal). At its left extremity the body tapers to form the tail, which usually touches the spleen (see DUPLICATE GLANDS) just below the hilum, and above the basal triangle of that viscus where the splenic flexure of the colon is situated. On the upper border of the body, a little to the left of the mid line of the abdomen, is a convexity or hump, which is known as the tuber omentale of the pancreas, and touches the elevation (bearing the same name) on the liver.

The pancreas is altogether behind the peritoneum. In its greater part it is covered in front by the lesser sac (see COLOM AND SEROUS MEMBRANES), but the portion behind the very narrow lower surface of the body and in contact with the greater sac. There is one main duct of the pancreas, which is sometimes known as the duct of Wirsung; it is thin-walled and straight, and in the last three sixth of its length on the front. As it reaches the head it turns downward and opens into the second part of the duodenum, joining the common bile duct while they are both piercing the walls of the gut. A smaller accessory duct, which opens into the duodenum, may be the main duct and usually opens into the duodenum about three-quarters of an inch above the papilla of the latter. It drains the lower part of the head, and either crosses or communicates with the duct of Wirsung to reach its opening (see A. Schirmer, Beitrag zur Geschichte und Anatomie des Pancreas, Basel, 1893).

The pancreas has no real capsule, but is divided up into lobules, which are merely held together by their ducts and by loose areolar tissue; the glands of which these lobules are made up are the acino-tubular variety (see EPITHELIAL TISSUES). Small groups of epithelium-like cells without ducts (Islets of Langerhans) occur among the glandular tissue and are characteristic of the pancreas. In cases of diabetes these epithelium cells degenerate. In the centre of each acinus of the main glandular tissue of the pancreas are often found spindle-shaped cells (centro-acinar cells of Langerhans). For details of microscopic structure see Essentials of Histology, by H. A. Schaffer (1907).

Embryology.—The pancreas is developed, by three diverticula, from that part of the foregut which will later form the duodenum. Of these diverticula the left ventral disappears early, but the right ventral, which is really an outgrowth from the lower part of the cardinal duct, divides into two ducts, the main duct and the tail, which are formed from the dorsal diverticulum, and the two parts, at first separate, join one another so that the ducts communicate, and eventually the ventral one takes almost all the secretion of the gland to the intestine, while that part of the dorsal one which is nearest the duodenum atrophies and forms the duct of Santorini. The main pancreatic duct (of Wirsung) is therefore formed partly by the ventral and partly by the dorsal diverticulum. As the diverticula grow they give off lateral branches, which break again and again until the terminal buds form the acini of the gland. At first the pancreas grows upward, behind the stomach, between the two layers of the dorsal mesogastrium (see COLOM AND SEROUS MEMBRANES), and at last, as the organ turns over to the right, the gland becomes horizontal and the opening of the right ventral diverticulum becomes more dorsal. Later, by the unequal growth of the duodenal walls, it comes to enter the body of the duodenum, and the ducts enter the gland and first open on the left side of the organ, then, with the turn over of the pancreas to the right the peritoneum is absorbed from its dorsal aspect. The islets of Langerhans are now regarded as portions of the glandular epithelium which have been separated by the action of the pancreas round them of mesenchyme (see Quain's Anatomy, vol. i, 1908).

Comparative Anatomy.—In the Acrania (Amphioxus) no representative of a pancreas has been found, but in the Cyclostomata (hagfishes and lampreys) there is a small lobular gland, which represents the bile duct which probably represents it. In the Elasmobranchs (sharks and rays) there is a definite compact pancreas of considerable size. In the Teleostomi, which include the true bony fish (Teleostei), the sturgeon and Polypterus, the pancreas is sometimes

1 N. W. Ingalls has shown (Archiv. f. mik. Anat. und Entwickelt. Bd. 70, 1907), that in a human embryo of 4-9 mm. the two ventral buds persist and join one another below the liver bud.
a compact gland and sometimes diffuse between the layers of the mesentery; at other times it is so surrounded by the liver as to be difficult to find.

Among the Dipnoi (mud fish). Protopterus has it embedded in the walls of the stomach and intestine.

The Amphibia have a definite compact pancreas which lies in the U-shaped loop between the stomach and duodenum, and is massed round the bile duct. In the Reptilia there are sometimes several ducts, as in the crocodile and the water tortoise (Emys), and this arrangement is also found in birds (the pigeon, for instance, has three ducts opening into the duodenum at very different levels). In mammals the gland is usually compact, though into the pancreas is of some medico-legal importance as being a cause of death. The condition is rarely recognized in time for operative interference. Acute haemorrhagic pancreatitis is a combination of inflammation with haemorrhage in which the pancreas is found enlarged and infiltrated with blood. Violent pain, vomiting and collapse, are the chief features as is also the case in pancreatic abscess in which the abscess may be single or multiple. In the latter case operation has been followed by recovery. Haemorrhagic inflammation has been followed by gangrene of the pancreas, which usually terminates fatally. In two remarkable cases, however, reported by Chiari recovery followed on the discharge of the necrosed pancreas. Chronic pancreatitis is said by

From Ambrose Birmingham, Cunningham's Text Book of Anatomy.

Fig. 1.—The Viscera and Vessels on the Posterior Abdominal Wall.

The stomach, liver and most of the intestines preserved on the right kidney, and the fossa for vena cava was left behind. The stomach-bed is

sometimes, as in the rabbit, it is diffuse. It usually has two ducts, as in man, though in many animals, such as the ox, sheep and goat, only one persists. When there is only one duct it may open with the common bile duct, e.g. sheep and cat, or may be very far away as in the ox and rabbit.

(R. G. P.)

Diseases of the pancreas.—As the pancreas plays an important part in the physiology of digestion much attention has of late been paid to the question of its secretions. In sclerosis, atrophy, acute and chronic inflammatory changes and new growths in the pancreas an absence or lessening of its secretion may be evident. Haemorrhage

Mayo Robson to occur in connexion with the symptoms of catarhal jaundice, which he suggests is due to the pressure on the common duct by the swollen pancreatic tissue. The organ is enlarged and very hard, and the symptoms are pain, dyspepsia, jaundice, loss of weight and the presence of fat in the stools. This latter sign is common to all forms of pancreatic disease. In connexion with all pancreatic diseases small yellowish patches are found in the pancreatic tissue, mesentery, omentum and abdominal fatty tissue generally, and the tissues appear to be studded with whitish areas often not larger than a pin's head. The condition, which was
first observed by Balsor, has been termed "fat-necrosis." The pancreas like other organs, is subject to the occurrence of new growths, tumours and cysts, syphilis and tuberculosis.

**PANDA (Aelurus fulgens),** a carnivorous mammal of the family Procyonidae (see CARNIVORA). This animal, rather larger than a cat, ranges from the eastern Himalaya to north-west China. In the former area it is found at heights of from 7000 to 12,000 ft. above the sea, among rocks and trees, and chiefly feeds on fruits and other vegetable substances. Its fur is of a remarkably rich reddish-brown colour, darker below; the face is white, with the exception of a vertical stripe of red from just above the eye to the gape; there are several pale rings on the tail, the tip of which is black.

**PANDARUS, in Greek legend,** son of Lycaon, a Lycian, one of the heroes of the Trojan war. He is not an important figure in Homer. He breaks the truce between the Trojans and the Greeks by treacherously wounding Menelaus with an arrow, and finally he is slain by Diomedes (Homer, IIiad, i. 927, iv. 88, v. 290). In medieval romance he became a prominent figure in the tale of Troilus and Cressida. He encouraged the amour between the Trojan prince and his niece Cressida; and the word "pander" has passed into modern language as the common title of a lovers' go-between in the worst sense.

**PANDECTS (Lat. pandecta),** adapted from Gr. πανδέκτης, all-containing, a name given to a compendium or digest of Roman law compiled by order of the emperor Justinian in the 6th century (A.D. 530-533). The pandects were divided into fifty books, each book containing several titles, divided into laws, and the laws into several parts or paragraphs. The number of jurists from whose works extracts were made is thirty-nine, but the writings of Ulpian and Paulus make up quite half the work. The work was declared to be the sole source of non-statute law: comments on the compilation were forbidden, or even the citing of the original works of the jurists for the expounding of ambiguities in the text. See Justinian; and Roman Law.

**PANDERMA (Gr. Panormus),** a town of Asia Minor, on the southern shore of the Sea of Marmora, near the site of Cyzicus. It has a trade in cereals, cotton, opium, valonia and boracite and is connected by a carriage road with Balikp. Pop. 10,000 (7000 Moslems).

**PANDHARPUR, a town of British India,** in Sholapur district of Bombay, on the right bank of the river Bhima, 38 m. W. of Sholapur town. Pop. (1901), 32,405. Pandharpur is the most popular place of pilgrimage in the Deccan, its celebrated temple being dedicated to Vishnava, a form of Vishnu. Three assemblages are held annually. In 1906 a light railway was opened to Pandharpur from Barsi Road on the Great Indian Peninsula railway.

**PANDORA (the "All-giving" ) in Greek mythology, according to** Hesiod (Theog., 570-612) the first woman. After Prometheus had stolen fire from heaven and bestowed it upon mortals Zeus determined to counteract this blessing. He accordingly commissioned Hephaestus to fashion a woman out of earth, upon whom the gods bestowed their choicest gifts. Hephaestus gave her a human voice, Aphrodite beauty and powers of seduction, Hermes cunning and the art of flattery. Zeus gave her a jar (nymos), the so-called "Pandora's box" (see below), containing all kinds of misery and evil, and sent her, thus equipped, to Epimetheus, who, forgetting the warning of his brother Prometheus to accept no present from Zeus, made her his wife. Pandora afterwards opened the jar, from which all manner of evils flew out over the earth (for parallels in other countries, see Farabi's Pandorisa, ii. 120). Hope alone remained at the bottom, the lid having been shut down before she escaped. (Hesiod, W. and D. 54-105). According to a later story, the jar contained, not evils, but blessings, which would have been preserved for the human race, had they not been lost through the opening of the jar out of curiosity by man himself (Babrius, Fab. 58).

See J. E. Harrison, "Pandora's Box," in Journal of Hellenic Studies, xx. (1900), in which the opening of the jar is explained as an aeriological myth based on the Athenian festival of the Pithoigia (part of the Anthesteria, q.v.), and P. Gardner, "A New Pandora vase" (xxii., ibid., 1901). Pandora is only another form of the Earth goddess, who is conceived as releasing evil spirits from the abyss, which are divided by a grave (cf. the removal of the lapis malnalis from the mundus, a circular pit at Rome supposed to be the opening to the world below, on three days in the year, whereby an opportunity of revisiting earth was afforded the dead). See also P. Guppe, Griechische Mythologie (1908), p. 94.

**PANDUA, a ruined city in Malda district of Eastern Bengal and Assam, once a Mahomedan capital. It is situated 7 m. N.E. of Malda, and about 20 m. from the other great ruined city of Gaur (q.v.), from which it was largely built. It was probably originally an outpost of Gaur, and grew in importance as Gaur became unhealthy. In A.D. 1553 Háji Shams-uddin Iyas, the first independent king of Bengal, transferred his capital from Gaur to Pandrau; but the time of its prosperity was short, and in A.D. 1553 the capital was transferred back to Gaur. Its only celebrated building is the Adina Mosque, which was described by James Fergusson as the finest example of Pathian architecture in existence. This great mosque was built by Sikandar Shah in 1659 (see Indian Architecture). Pandua now, like Gaur, is almost entirely given over to the jungle.

**PANDULPH [Pandolfo] (d. 1226),** Roman ecclesiastical politician, papal legate to England and bishop of Norwich, was born in Rome, and first came to England in 1211, when he was commissioned by Innocent III. to negotiate with King John. Obtaining no satisfactory concessions, he is said to have produced the papal sentence of excommunication in the very presence of the king. In May 1213 he again visited England to receive the king's submission. The ceremony took place at Dover, and on the following day John, of his own motion, formally surrendered England to the representative of Rome to receive it again as a papal fief. Pandulph repaid this act of humility by using every means to avert the threatened French invasion of England. For nearly a year he was superseded by the cardinal-legate Nicholas of Tusculum; but returning in 1215 was present at the conference of Runnymede, when the great charter was signed. He rendered valuable aid to John who rewarded him with the see of Norwich. The arrival of the cardinal-legate Guado (1216) relegated Pandulph to a secondary position; but after Guado's departure (1218) he came forward once more. As representing the pope he claimed a control over Hubert de Burgh and the other ministers of the young Henry III.; and his correspondence shows that he interfered in every department of the administration. His arrogance was tolerated while the regency was still in need of papal assistance; but in 1221 Hubert de Burgh and the primate Stephen Langton successfully moved the pope to recall Pandulph and to send no other legate a latere in his place. Pandulph retained the see of Norwich, but from this time drops out of English politics. He died in Rome on the 16th of September 1226 but his body was taken to Norwich for burial.

See W. Shirley, Royal and Other Historical Letters ("Rolls series") vol. i.; Miss K. Norgate, John Lackland (1902); W. Stubbs, Constitutional History (1897) vol. i.

**PANDURA (tambura, tanbur, tambora, mandora, pandore, bandora, bandoer, &c.),** an ancient oriental stringed instrument, a member of the lute family, having a long neck, a highly-vaulted back, and originally two or three strings plucked by the fingers. There were in antiquity at least two distinct varieties of pandura, or tanbur. (1) The more or less pear-shaped type used in Assyria and Persia and introduced by way of Asia Minor into Greece, whence it passed to the Roman Empire. In this type, the soundbox was slightly convex and the soundpost was a rather dull, outward-curved line which led up gradually from base to neck were replaced by a more sloping outline, approximated to an elongated triangle with the corners rounded off. (2) The oval type, a favourite instrument of the Egyptians, also found in ancient Persia and among the Arabs of North Africa, who introduced it into Spain. Our definite knowledge of the pandura is derived from the treatise on music by Fārābī, the Arab scholar who flourished

---

PANE—PANEGYRIC

in the 10th century. He mentions two kinds of tanburs, devoting to each a chapter, i.e. the tanburn of Khorasan, the Persian type, and the tanburn of Bagdad, the Assyrian variety; these differ in form, in length, and in the arrangement of the frets. Unfortunately, Farabi does not describe the shape of the body being more concerned with the musical scale and compass of the instrument; but means of identification are supplied by ancient monuments. There is a tanburn on an Assyrian bas-relief of the reign of Assur-nasir-pal, c. 880 B.C. (British Museum), on a slab illustrating camp life; the musician is playing on a pear-shaped tanburn with a very long slender neck, which would have served for two strings at the most, while two men, disguised in the skins of wild beasts, are dancing in front of him.

There were in Farabi's day five frets at least, whereas on the tanburn of Khorasan there were no fewer than eighteen, which extended for half the length of the instrument. Five of these frets were fixed, and invariable in position, the other thirteen being interpolated between them. The fixed frets, counting from the nut, gave an interval of one tone to the first, of a fourth to the second, of a fifth to the third, of an octave to the fourth, and of a major ninth to the fifth, thus providing a succession of fourths and fifths. The additional frets were placed between these, so that the octaves generally contained seventeen intervals of one tone each. The two principal accordances for the tanburn of Khorasan were the *marriage* when the strings were in unison, and the *lute* or accordance in fourths. Farabi mentions a tail-piece or *sobâha*, to which the strings, generally two in number but sometimes three, were attached; they rested on a bridge provided with as many notches as there were strings. In the tanburn of Khorasan they were wound round pegs placed opposite each other in the two sides of the head, as in the modern violin.

Pollux¹ states that the pandura was invented by the Assyrians or the Egyptians, and had three strings. Thomæ Reinaud's opinion that pandura was a generic term for instruments of the lute type during the Roman and Alexandrine periods. This may be the case, but from the modern standpoint we cannot in our classification adhere to diatonic the invariable characteristics observed in the modern, no less than in the ancient and medieval, tanburns or panduras.

To be able to identify the pandura it is as well to bear in mind the distinctive features of other instruments with which it might be confounded. The tanburn had a long neck resembling a section of a cylinder and a highly vaulted back, and its strings were placed. In the rebab the neck was wanting or at best rudimentary. In the pandura the back of the head and, during the middle ages in Europe, as rebâb, it was always a bowed instrument. The early lutes had larger bodies than the tanburn, the neck was short compared to the length of the body, the head generally a rectangular shape at right angles to the back, and the sound-board was not so deeply vaulted as that of the tanburn. The barbiton or bass lute had a long neck also, but wider, to take six, seven, or even nine strings, and from the back or profile view the general appearance of a pear-shaped instrument.

Unlike the Romans the panduras had become somewhat modified; the long neck was preserved but was made wider to take four strings, and the body was either oval or slightly broader at the base, but without the inward curves of the pear-shaped instruments. A scale popular among the panduras was that of the Townley Collection, at the British Museum on a back-illustrating the marriage feast of Eros and Psyche, a Roman sculpture assigned to c. 150 B.C. This is an example of great value to the archaeologist, being the earliest extant instrument that has been studied in full and in profile. The arrangement of the four pegs in the back of the head is Oriental.

The Persians had a six-stringed tanburn, which they distinguished as the *schechta*, whereas a three-stringed variety was known as the *schrud*.

The tanburn survived during the middle ages and as late as the 18th century; it may be traced in the musical documents of several countries. In England the number of strings on a tanburn was limited to an instrument with wire strings having no characteristic structural feature in common with the ancient tanburn but resembling the cittern (q.v.). The bandon did a flat back and sound-board joined by ribs having a number of frets. The tanburn was an instrument called *orphon* and a larger and wider *penorcon*; these are described and figured by Praetorius, who suggests that this instrument, invented in England as a bandon, is probably similar to the *pandora*. The *bandoer* of Sir Philip Leicester's¹ index to his commonplace book of 1575, invented by "John Rose dwellings in Bridewell anno 46 Elizabeth, who left some farre exceedinge himself in making it." (K. S.)

PANE (Fr. pan, Lat. pannus, a cloth, garment), originally a piece of cloth, especially one of a number of pieces of cloth or other material joined to form one piece for a garment; the word is also used to the "shakes" in the material of a dress made to show a rich lining or the colour of a lining when different from the outside material. The word "bandon," a fragment of the ancient Oriental tanburn, with nine strings, a rose sound hole, and seven frets; the French writer erroneously states that it is similar to the cittern (q.v.). Filippo Bonanni² gives an illustration of the same kind of instrument, with ten strings in five pairs of unisons, and calls it *pandura*.

PANE (Fr. pan, Lat. pannus, a cloth, garment), originally a piece of cloth, especially one of a number of pieces of cloth or other material joined to form one piece for a garment; the word is also used to the "shakes" in the material of a dress made to show a rich lining or the colour of a lining when different from the outside material. The word "bandon," a fragment of the ancient Oriental tanburn, with nine strings, a rose sound hole, and seven frets; the French writer erroneously states that it is similar to the cittern (q.v.). Filippo Bonanni² gives an illustration of the same kind of instrument, with ten strings in five pairs of unisons, and calls it *pandura*.

PANE, strictly a formal public speech delivered in high praise of a person or thing, and generally high studied or undiscriminating eulogy. It is derived from *paphyrgos* (a speech) "fit for a general assembly" (*paphyrgos, panegyris*). In Athens such speeches were delivered at national festivals or games, with the object of rousing the citizens to emulate the hero, the hero's deeds or his ancestors. The most famous are the *Olympiaca* of Gorgias, the *Olympiaca* of Lysias, and the *Panegyricus* and *Panathenaeus* (neither of them, however, actually delivered) of Isocrates. Funeral orations, such as the famous speech put into the mouth of Pericles by Thucydides, also partook of the nature of panegyrics. The Romans confined the panegyric to the living, and reserved the funerary oration exclusively for the dead. The most celebrated example of a Latin panegyric (*panegyricus*) is that delivered by the younger Pliny (A.D. 100) in the senate on the occasion of his assumption of the consulship, containing a somewhat fulsome eulogy of Trajan. Towards the end of the 3rd and during the 4th century, as a result of the orientalizing of the Imperial court by Diocletian, it became customary to celebrate as a matter of course the superhuman virtues and achievements of the reigning emperor. Thus, all courtiers were taught the art of *sprecherei*. The high achievements of the famous Gallic rhetoricians (Claudius Mamertinus, Eumenius, Nazarius, Drepanius Pacatus) and three of anonymous authorship, have been collected under the title of *Panegyrici veteres latini* (ed. E. Bährs, 1874). Speaking generally, they are characterized by a stilted, affected style and a tone of gross adulation. There are extant similar orations by Ausonius, six or seven strings, one played by a Moor; both have the tail-piece in the form of a crescent.

**PANEL** (O. Fr. panel, mod. paneau, piece of cloth, from Med. Lat. *panellus*, diminutive of *pannis*, cloth), a piece of cloth, slip of parchment, or portion of a surface of wood or stone enclosed in a compartment. In the first sense the word survives in the use of "panel" or "pannel" for the cloth-stuffed lining of a saddle. From the slip of parchment on which the list of jurymen is drawn up by the sheriff, "panel" in English law is applied to a jury, who are thus said to be "empanelled." In Scots law the word is used of the indictment, and of the prisoner or persons named in the indictment; "panel" is thus the equivalent of the English "prisoner at the bar." In building and architecture (Fr. *panneau*; Ital. *quadretto*, *formelle*; Ger. *Feld") "panel" is properly used of the piece of wood framed within the stiles and rails of a door, filling up the aperture; but it is often applied both to the whole square frame and the sinking itself, and also to the ranges of sunken compartments in cornices, corbel tables, groined vaults, ceilings, &c. In Norman work these recesses are generally shallower, and more of the nature of *arcades.* In Early English work the square panels are ornamented with quatrefoils, cusped circles, &c., and the larger panels are often deeply recessed, and form niches with trefoil heads and sometimes canopies. In the Decorated style the cusping and other enrichments of panels become more elaborate, and they are often filled with shields, foliage, and sometimes figures. Towards the end of the period the walls of important buildings were often entirely covered with long or square panels, the former frequently forming niches with statues. The use of panels in this way became very common in Perpendicular work, the wall frequently being entirely covered with long, short and square panels, which latter are often keyed or cusped, and filled with every variety of devices, such as shields, bosses of foliage, portcullis, lilies, Tudor roses, &c. Wooden panelings very much resembled those of stone, except in the Tudor period, when the panels were enriched by a varied design, imitating the plaits of a piece of linen or a napkin folded in a great number of parallel lines. This is generally called the *linen pattern.* Wooden ceilings, which are very common, are composed of thin oak boards nailed to the rafters, collars, &c., and divided into panels by oak mouldings fixed on them, with carved bosses at the intersections.

**PANETHESM,** the name given by K. C. F. Krause (q.v.) to his philosophic theory. Krause held that all existence is one great unity, which he called *Wesen* (Essence). This Essence is God, and includes within itself the finite unities of man, reason and nature. God therefore includes the world in Himself and extends beyond it. The theory is a conciliation of Theism and Panism.

**PANGOLIN,** the Malay name for one of the species of the scaly anteaters, which belong to the order *Edentata* (q.v.), and typify the family *Manidae* and the genus *Manis.* These animals, which might be taken for reptiles rather than mammals, are found in the warmer parts of Asia and throughout Africa. Pangolins range from 1 to 3 ft. in length, exclusive of the tail, which may be much shorter than or nearly twice the length of the rest of the animal. Their legs are short, so that the body is only a few inches off the ground; the ears are very small; and the tongue is long and worm-like, and used to capture ants. Their most striking character, however, is the coat of broad overlapping horny scales, which cover the whole animal, with the exception of the under surface of the body, and in some species the lower part of the tip of the tail. Besides the scales there are generally, especially in the Indian species, a number of isolated hairs, which grow between the scales, and are scattered over the soft and flexible skin of the belly. There are five toes on each foot, the claws on the first toe rudimentary, but the others, especially the third of the forefoot, long, curved, and

laterally compressed. In walking the fore-claws are turned backwards and inwards, so that the weight of the animal rests on the back and outer surfaces, and the points are thus kept from becoming blunted. The skull is long, smooth and rounded, with imperfect zygomatic arches, no teeth of any sort, and, as in other ant-eating mammals, with the bony palate extending unusually far backwards towards the throat. The lower jaw consists of a pair of thin rod-like bones, welded to each other at the chin, and rather loosely attached to the skull by a joint which, instead of being horizontal, is tilted up at an angle of 45°, the outwardly-twisted condyles articulating with the inner surfaces of the long glabeloid processes in a manner unique among mammals.

The genus *Manis,* which contains all the pangolins, may be conveniently divided into two groups, distinguished by geographical distribution and certain convenient, though not highly important, external characters. The Asiatic pangolins are characterized by having the central series of body-scales continued to the extreme end of the tail, by having many isolated hairs growing between the scales of the back, and by their small external ears. They all have a small naked spot beneath the tip of the tail, which is said to be of service as an organ of touch. There are three species: viz. *Manis javanica,* ranging from Burma, through the Malay Peninsula and Java, to Borneo; *M. aurita,* found in China, Formosa and Nepal; and the Indian Pangolin, *M. pentadactyla,* distributed over the whole of India and Ceylon. The African species have the central series of scales suddenly interrupted and breaking into two at a point about 2 or 3 in. from the tip of the tail; they have no hair between the scales, and no external ears. The following four species belong to this group: the long-tailed pangolin (*M. maccuro*), with a tail nearly twice as long as its body, and containing as many as forty-six caudal vertebræ, nearly the largest number known among Mammals; the white-bellied pangolin (*M. tricuspis*), closely allied to the last, but with longer three-lobe scales, and white belly hairs; and the short-tailed and giant pangolins (*M. temmincki* and *gigantea*), both of which have the tail covered entirely with scales. Those species with a naked patch on the under side of the tail can climb trees. The four species of the second group are found in West Africa, although some extend into south and eastern equatorial Africa.

(O. T.; R. L.*)

**PANIN, NIKITA IVANOVIICH, COUNT** (1718-1783), Russian statesmen, was born at Danzig on the 15th of September 1718. He passed his childhood at Pernau, where his father was commandant. In 1740 he entered the army, and rumour had it that he was one of the favourites of the empress Elizabeth. In 1747 he was accredited to Copenhagen as Russian minister,
but a few months later was transferred to Stockholm, where for the next twelve years he played a conspicuous part as the chief opponent of the French party. It is said that during his residence in Sweden Panin, who certainly had a strong speculative bent, conceived a fondness for constitutional forms of government. Politically he was a pupil of Alexis Bestuzhev; consequently, when in the middle 'fifties Russia suddenly turned Francophil instead of Francophobe, Panin's position became extremely difficult. However, he found a friend in Bestuzhev's supplanter, Michael Vorontsov, and when in 1760 he was unexpectedly appointed the governor of the little grand duke Paul, his influence was assured. He was on Catherine's side during the revolution of 1762, but his jealousy of the influence which the Orlows seemed likely to obtain over the new empress predisposed him to favour the proclamation of his ward the grand duke Paul as emperor, with Catherine as regent only.

To circumscribe the influence of the ruling favourites he next suggested the formation of a cabinet council of six or eight ministers, through whom all the business of the state was to be transacted; but Catherine, suspecting in the skilfully presented novelty a subtle attempt to limit her power, rejected it after some hesitation. Nevertheless Panin continued to be indispensable. He owed his influence partly to the fact that he was the governor of Paul, who was greatly attached to him; partly to the peculiar circumstances in which Catherine had mounted the throne; and partly to his knowledge of foreign affairs. Although acting as minister of foreign affairs he was never made chancellor; but he was the political mentor of Catherine during the first eighteen years of her reign. Panin was the inventor of the famous "Northern Accord," which aimed at opposing a combination of Russia, Prussia, Poland, Sweden, and perhaps Great Britain, against the Bourbon-Habsburg League. Such an attempt to bind together nations with such different aims and characters was doomed to failure. Great Britain, for instance, could never be persuaded that it was as much in her interests as in the interests of Russia to subsidize the anti-French party in Sweden. Yet the idea of the "Northern Accord," though nevce quite realized, had important political consequences and influenced the policy of Russia for many years. It explains, too, Panin's strange tenderness towards Poland. For a long time he could not endure the thought of destroying her, because he regarded her as an indispensable member of his "Accord," wherein she was to supply the place of Austria, whose circumstances had temporarily detached from the Russian alliance. Poland, Panin opined, would be especially useful in case of Oriental combinations. All the diplomatic questions concerning Russia from 1702 to 1783 are intimately associated with the name of Panin. It was only when the impossibility of realizing the "Northern Accord" became patent that his influence began to wane, and Russia sacrificed millions of roubles fruitlessly in the endeavour to carry out his pet scheme.

After 1772, when Gustavus III. upset Panin's plans in Sweden, Panin, whose policy hitherto had been at least original and independent, became a part of the tardy policy of Catherine II. of Poland. As to Poland, his views differed widely from the views of both Frederick and Catherine. He seriously guaranteed the integrity of Polish territory, after placing Stanislaus II. on the throne, in order that Poland, undivided and as strong as circumstances would permit, might be drawn wholly within the orbit of Russia. But he did not foresee the complications which were likely to arise from Russia's interference in the domestic affairs of Poland. Thus the confederation of Bar, and the Turkish War thereupon ensuing, took him completely by surprise and considerably weakened his position. He was forced to acquiesce in the first partition of Poland, and when Russia came off third best, Gregory Orlov declared in the council that the minister who had signed such a partition treaty was worthy of death. Panin further incensed Catherine by meddles with the marriage arrangements of the grand duke Paul and by advocating a closer alliance with Prussia, whereas the empress was beginning to incline more and more towards Austria. Nevertheless, even after the second marriage of Paul Panin maintained his old influence over his pupil, who, like Panin himself, was now a firm admirer of the king of Prussia. There are even traditions from this period of an actual conspiracy of Panin and Paul against the empress. As the Austrian influence increased Panin found a fresh enemy in Joseph II., and the efforts of the old statesman to prevent a matrimonial alliance between the Russian and Austrian courts determined Catherine to get rid of a counsellor of whom, for some mysterious reason, she was secretly afraid. The circumstances of his disgrace are complicated and obscure. The final rupture seems to have arisen on the question of the declaration of "the armed neutrality of the North;" but we know that Potemkin and the English ambassador, James Harris (afterwards 1st earl of Malmesbury), were both working against him some time before that. In May 1781 Panin was dismissed. He died in Italy on the 31st of March 1783. Panin was one of the most learned, accomplished and courteous Russians of his day. Catherine called him her "encyclopaedia." The earl of Buckinghamshire declared him to be the most amiable negotiator he had ever met. He was also of a most humane disposition and a friend of liberal institutions. As to his honesty and kindness of heart there were never two opinions. By nature a sybarite, he took care to have the best cook in the capital, and women had for him an irresistible attraction, though he was never married.

Bilbasov, Geschichtle Katharina II. (Berlin, 1891-1903); A. Birckner, Materials for the Biography of Count Panin (Rus.; St Petersburg, 1888).

(R. N. B.)

PANIPAT, a town of a British India, in Karnal district of the Punjab, 53 m. N. of Delhi by rail. Pop. (1901), 26,614. The town is of great antiquity, dating back to the great war of the Mahabharata between the Pandavas and Kaurava brethren, when it formed one of the tracts demanded by Yudhisthira from Duryodhan the prince for peace. In modern times, the plains of Panipat thrice formed the scene of decisive battles which decided the fate of upper India—"in 1526, when Bāber completely defeated the imperial forces; in 1556, when his grandson, Akbar, on the same battlefield, conquered Humāu, the Hindu general of the Afghan Adil Şāh, thus a second time establishing the Mogul power; and finally, on the 7th of January 1761, when Ahmad Shāh Durrānī shattered the Mahratta confederacy. The neighbourhood is a favourite mancuring ground for British camps of instruction. The modern town stands near the old bank of the Jumna, on high ground composed of the débris of earlier buildings. It is a centre of trade, and has manufactures of cotton cloth, metal-ware and glass. There are factories for ginning and pressing cotton.

PANIZZI, SIR ANTHONY (1797-1879), English librarian, was born at Brescello, in the duchy of Modena, Italy, on the 16th of September 1797. After taking his degree at the University of Parma, Antonio Panizzi became an advocate. A fervent patriot, he was implicated in the movement set on foot in 1821 by Donizetti to expel the Spanish and make Modena an independent principality. He discharged with bravery the duties of a member of the civic guard; but when the French appeared in the number of that barey escaped arrest by a precipitate flight. He first established himself at Lugano, where he published an anonymous and now excessively rare pamphlet, generally known as I Processi di Rubiera, an exposure of the monstrous injustice and illegalities of the Modenese government's proceedings against suspected persons. Expelled from Switzerland at the joint instance of Austria, France and Sardinia, he came to England in May 1823, in a state bordering upon destitution. His countryman, Ugo Foscolo, provided him with introductions to William Roscoe and Dr William Shepherd, a Unitarian minister in Liverpool, and he earned a living for some time by giving Italian lessons. Roscoe introduced him to Brougham, by whose influence he was made, in 1828, professor of Italian at University College, London. His chair was almost a sinecure; but his abilities rapidly gained him a footing in London; and in 1831 Brougham, then lord chancellor, used his e/s officio position as a principal trustee of the British Museum to obtain for Panizzi
the post of an extra assistant librarian of the Printed Book department. At the same time he was working at his edition of Boiardo’s Orlando innamorato. Boiardo’s fame had been eclipsed for three centuries by the adaptation of Bern; and it is highly to the credit of Panizzi to have redeemed him from oblivion and restored to Italy one of the very best of her narrative poets. His edition of the Orlando innamorato and the Orlando furioso was published between 1830 and 1834, prefaced by a valuable essay on the influence of Celtic legends on medieval romance. In 1835 he edited Boiardo’s minor poems, and was about the same time engaged in preparing a catalogue of the library of the Royal Society.

The unsatisfactory condition and illiberal management of the British Museum had long excited discontent, and at length a trivial circumstance led to the appointment of a parliamentary committee, which sat throughout the sessions of 1835–1836, and probed the condition of the institution very thoroughly. Panizzi’s principal contributions to its inquiries with regard to the library were an enormous mass of statistics respecting foreign libraries, and some admirable evidence on the catalogue of printed books then in contemplation. In 1837 he was appointed keeper of printed books. The entire charge of the Library, had he been removed from Montague House to the new building, the reading-room service had to be reorganized; rules for the new printed catalogue had to be prepared, and the catalogue itself undertaken. All these tasks were successfully accomplished; but, although the rules of cataloguing devised by Panizzi and his assistants have become the basis of subsequent work, progress of the catalogue itself was slow. The first volume, comprising letter A, was published in 1841, and from that time, although the catalogue was continued and completed in MS., no attempt was made to print any more until 1881. The chief cause of this comparative failure was injudicious interference with Panizzi, occasioned by the impatience of the trustees and the public. Panizzi, appointed, as that of a foreigner, had from the first been highly unpopular. He gradually broke down opposition, partly by his social influence, but far more by the sterling merits of his administration and his constant efforts to improve the library. The most remarkable of these was his report, printed in 1845, upon the museum’s extraordinary deficiencies in general literature, which ultimately procured the increase of the annual grant for the purchase of books to £10,000. His friendship with Thomas Grenville (1755–1846) led to the nation being enriched by the bequest of the unique Grenville library, valued even then at £50,000. In 1847–1849 a royal commission sat to inquire into the general state of the museum, and Panizzi was the centre of the proceedings. His administration, fiercely attacked from many quarters, was triumphantly vindicated in every point. Panizzi immediately became by far the most influential official in the museum, though he did not actually succeed to the principal librarianship until 1856. It was thus as merely keeper of printed books that he conceived and carried out the achievement by which he is probably best remembered—the erection of the new library and reading-room. Purchases had been discouraged from lack of room in which to deposit the books. Panizzi cast his eye on the empty quadrangle adjoining by the neighbour building, and the idea of occupying it with a central cupola too distant, and adjacent galleries too low, to obstruct the inner windows of the original edifice. The cupola was to cover three hundred readers, the galleries to provide storage for a million of books. The original design, sketched by Panizzi’s own hand on the 18th of April 1853, was submitted to the trustees on the 5th of May; in May 1854 the necessary expenditure was sanctioned by parliament, and the building was opened in May 1857. Its construction had involved a multitude of ingenious arrangements, all of which had been contrived or inspected by Panizzi, who had a genius for minute detail and a gift for mechanical invention.

Panizzi succeeded Sir Henry Ellis as principal librarian in March 1856. During his tenure of this post a great improvement was effected in the condition of the museum staff by the recognition of the institution as a branch of the civil service, and the decision was taken to receive the natural history collections to Kensington. Of this questionable measure Panizzi was a warm advocate; he was heartily glad to be rid of the naturalists. He had small love for science and its professors, and, as his friend Macaulay said, “would at any time have given three mummies for one Aldus.” Many important additions to the collections were made during his administration, especially the Temple bequest of antiquities, and the Haliçarnassian sculptures discovered at Budrun (Halicarnassus) by C. T. Newton. Panizzi retired in July 1866, but continued to interest himself actively in the affairs of the museum until his death, on the 8th of April 1879. He had been created a K.C.B. in 1869.

Panizzi had become a naturalized Englishman, but his devotion to the British Museum was rivaled by his devotion to his native land, and his personal influence with English Liberal statesmen enabled him often to promote her cause. Throughout the revolutionary movements of 1848–1849, and again during the campaign of 1859 and the subsequent transactions due to the squeezing of Naples by the kingdom of upper Italy, Panizzi was in constant communication with the Italian patriots and their confidential representative with the English ministers. He laboured, according to circumstances, now to excite, now to mitigate, the English jealousy of France; now to moderate their apprehensions of revolutionary excesses; now to secure encouragement or connivance for Garibaldi. The letters addressed to him by patriotic Italians, edited by his literary executor and biographer, L. Fagan, alone compose a thick volume. He was charitable to his exiled countrymen in England, and, chiefly at his own expense, equipped a steamer, which was lost at sea, to rescue the Neapolitan prisoners of state on the island of Santo Stefano. His services were recognized by the offer of a senatorship and of the direction of public instruction in Italy; these offers he declined, though in his latter years he frequently visited the land of his birth.

His administrative faculty was extraordinary; to the widest grasp he united the minutest attention to matters of detail. By introducing these ideas into the management of the museum he not only redeemed it from being a mere show-place, but raised the standard of library administration all over England. His moral character was the counterpart of his intellectual: he was warm-hearted and magnanimous; extreme in love and hate—a formidable enemy, but a devoted friend. His intimate friends included Lord Palmerston, Gladstone, Roscoe, Grenville, Macaulay, Lord Langdale and his family, Rutherford (lord advocate), and, above all perhaps, Francis Haywood, the translator of Kant. His most celebrated friendship, however, is that with Prosper Mérimée, who, having begun by seeking to enlist his influence with the English government on behalf of Napoleon III., discovered a congeniality of tastes which produced a delightful correspondence. Mérimée’s part has been published by Fagan; Panizzi’s perished in the conflagration kindled by the Paris commune.

See Fagan, Life of Sir Henry Panizzi (Lon.: 1880). (R.G.)

**PANJABI** (properly Panjabi), the language of the Central Punjab (properly Panzab), It is spoken by over 71,000,000 people between (approximately speaking) the 77th and 74th degrees of east longitude. The vernacular of this tract was originally an old form of the modern Lahndâ, a member of the outer group of Indo-Aryan languages (q.v.), but it has been overlaid by the expansion of the midland Sauraseni Prakrit (see Pârâkrit) to its east, and now belongs to the intermediate group, possessing most of the characteristics of the midland language, with occasional traces of the old outer basis which become more and more prominent as we go westwards. At the 74th degree of east longitude we find it merging into the modern Lahndâ. The language is fully described in the article Hindostani.

**PANJDEH, or Pânjdeh**, a village of Russian Turkstein, rendered famous by “the Panjdeh scare” of 1885. It is situated on the east side of the Kusht river near its junction with the
Murgab at Puli-Khishiti. In March 1885 when the Russo-Afghan Boundary Commission should have been engaged in settling the boundary line, this portion of it was in dispute between the Afghans and the Russians. A part of the Afghan force was encamped on the west bank of the Kushk, and on the 20th of March General Komarov sent an ultimatum demanding their withdrawal. On their refusal the Russians attacked them at 3 a.m. on the 30th of March and drove them across the Puli-Khishiti Bridge with a loss of some 600 men. The incident nearly give rise to war between England and Russia; but the Amir Abdur-Rahman, who was present at the Rawalpindi conference with Lord Dufferin at the time, affected to regard the matter as a mere frontier scuffle. The border-line subsequently laid down gives to Russia the corner between the Kuschk and Murgab rivers as far as Maruchak on the Murgab, and the Kushk post has now become the frontier post of the Russian army of occupation.

PANNA, or PUNNA, a native state of Central India, in the Bundelkhand agency. Area, 2492 sq. m. (pop. 1901), 102,986, showing a decrease of 15% in the preceding decade due to famine, to the tribute f.33,000. The chief, whose title is maharaja, is a rajput of the Bundela clan, descended from Chhatar Sal, the champion of the independence of Bundelkhand in the 18th century. The maharaja Lokpal Singh died in 1898, leaving an only son, Madho Singh, who, in 1902, was found guilty by a special commission on the charge of poisoning his uncle, and was deposed. The diamond mines, for which the state was formerly famous, are now scarcely profitable. There are no railways, but one or two good roads. The town of Panna is 62 m. S. of Banda. Pop. (1901), 11,346. It has a fine modern palace and several handsome temples and shrines.

PANNAGE (O. Fr. pannage, from Med. Lat. pasnagium, pastrainium for pastriacum, passio; passare, to feed), an English legal term for the feeding of swine in a wood or forest, hence used of a right or privilege to do this. The word is also used generally of the food, such as acorns, beechnast, &c., on which the swine feed.

PANNIER (Fr. panier, Lat. panarium, a basket for carrying bread, panis), a basket for carrying bread or other provisions; more especially a broad, flat basket, generally slung in pairs across a mule, pony or ass for transport. The term has also been applied to an overskirt in a woman's dress attached to the back of the bodice and draped so as to give a "bunchy" appearance. At various times in the history of costume this appearance has been produced by a framework of padded whalebone, steel, &c., used to support the dress, such frameworks being known as "panniers." At the Inns of Court, London, there was formerly an official known as a "pannier man," whose duties were concerned with procuring provisions at market, blowing the horn before meals, &c. The office has been in many of the inns long obsolete, and was formally abolished at the Inner Temple in 1900. At the Inner Temple the robed waiters in hall have called "panniers," and apparently were in some way connected with the officer above mentioned, but the proper duties of the two were in no way identical.

PANNONIA, in ancient geography a country bounded north and east by the Danube, conterminous westward with Noricum and upper Italy, and southward with Dalmatia and upper Moesia. It thus corresponds to the south-western part of Hungary, with portions of lower Austria, Styria, Carniola, Croatia, and Slavonia. Its original inhabitants (Pannonii, sometimes called Paenoni by the Greeks) were probably of Illyrian race. From the 4th century B.C. it was invaded by various Celtic tribes, probably survivors of the hosts of Brennus, the chief of whom were the Carini, Scordisci and Taurisci. Little is heard of Pannonia until 35 B.C., when its inhabitants, having taken up arms in support of the Dalmatians, were attacked by Augustus, who conquered and occupied Siscia (Sissek). The country was not, however, definitely subdued until 9 B.C., when it was incorporated with Illyria, the frontier of which was thus extended as far as the Danube. In A.D. 7 the Pannonians, with the Dalmatians and other Illyrian tribes, revolted, and were overcame by Tiberius and Germanicus, after a hard-fought campaign which lasted for two years. In A.D. 10 Pannonia was organized as a separate province—according to A. W. Zumpt (Studia roman.): not till A.D. 20; at least, when the three provinces stationed there mutinied after the death of Augustus (A.D. 14), Junius Blaesus is spoken of by Tacitus (Annals, i. 16) as legate of Pannonia and commander of the legions. The proximity of dangerous barbarian tribes (Quadi, Marcomanni) necessitated the presence of a large number of troops (seven legions in later times), and numerous fortresses were built on the bank of the Danube. Some time between the years 102 and 107, which marked the termination of the first and second Dacian wars, Trajan divided the province into Pannonia superior (Seleucia), the western, and inferior (sector), the eastern portion. According to Ptolemy, these divisions were separated by a line drawn from Arrabona (Raab) in the north to Servitium (Bratislava) in the south; later, the boundary was placed farther east. The whole country was sometimes called the Pannoniae (Pannoniorum). Pannonia superior was under the consular legate, who had formerly administered the single province, and had three legions under his control; Pannonia inferior at first under a praetorian legate with a single legion as garrison, after Marcus Aurelius under a consular legate, still with only one legion. The frontier on the Danube was protected by the establishment of the two colonies Aelia Mursia (Essa) and Aelia Aquinum (Alt-Ofen, modern Buda) by Hadrian.

Under Diocletian a fourfold division of the country was made. Pannonia inferior was divided into (1) Valeria (so called from Diocletian's daughter, the wife of Galerius), extending along the Danube from Altimunum (Mohacs) to Brigetio (Ö-Szobó), and (2) Pannonia secunda, round about Sirmium (Mitrovitz) at the meeting of the valleys of the Save, Drave, and Danube. Pannonia superior was divided into (3) Pannonia prima, its northern, and (4) Savia (also called Pannonia ripariensis), its southern part. Valeria and Pannonia prima were under a praetorian legate, and Pannonia secunda under a consularis and a dux; Savia under a dux and, later a legatus. In the middle of the 5th century Pannonia was ceded to the Huns by Theodosius II, and after the death of Attila successively passed into the hands of the Ostrogoths, Lombards, and Avars.

The inhabitants of Pannonia are described as brave and warlike, but cruel and treacherous. Except in the mountainous districts, the country was fairly productive, especially after the great forests had been cleared by Probus and Galerius. Before that time timber had been one of its most important exports. Its chief agricultural products were oats and barley, from which the inhabitants brewed a kind of beer named sabaca. Vines and olive-trees were little cultivated, the former having been first introduced in the neighbourhood of Sirmium by Probus. Salvia (Celtic, nard) was a common growth, as in Noricum. Pannonia was also famous for its breed of hunting-dogs. Although the consentation of one of its mineral wealth by the ancients, it is probable that it contained iron and silver mines. Its chief rivers were the Drave (Drave), Savus (Save), and Arrabo (Raab), in addition to the Danuvius (less correctly, Danubius), into which the three rivers flow.

The native settlements consisted of pagi (cantons) containing a number of tici (villages), the majority of the large towns being of Roman origin. In Upper Pannonia were Vindobona (Vienna), probably founded by Vespasian; Carnuntum (q.v., Petronell); Arrabona (Raab), a considerable military station; Brigetio; Savaria or Sabaria (Stein-am-Anger), founded by Claudius, a frequent residence of the later emperors, and capital of Pannonia prima; Poetovio (Pettau); Siscia, a place of great importance down to the end of the empire; Emona (Laitz), later assigned to Italy; Nauportus (Ober-Laibach). In Lower Pannonia were Sirmium, first mentioned in A.D. 6, also a frequent residence of the later emperors; Sopianae (Fünfkirchen), seat of the præfectus of Valeria, and an important place at the meeting of five roads; Aquincum, the residence of the dux of Valeria, the seat of legio ivia adiutrix.
PANOPHY—PANSY

681

See J. Marquardt, Römische Staatsverwaltung, i. (2nd ed., 1881), 291; Corpus inscriptionum latinarum, iii. 415; G. Zöppel, Die römische Herrschaft in Iliyen (Leipzig, 1877); Mommsen, Provinces of the Roman Empire (Eng. trans.), i. 22, 35; A. Forbiger, Handbuch der allern Geographie von Europa (Hamburg, 1877); Ptolemy, ii. 15, 16; Pliny, Nat. H. ii. 28; Strabo vii. 315; Dio Cassius xiii. 34-38, iv. 31-34, Iv. 28-32; Vell. Pat. ii. 110.

PANOPHY, a complete suit of armour. The word represents the Gr. πανοραμά (παν, all, and ὅραμα, armis), the full armour of a hoplite or heavy-armed soldier, i.e. the shield, breastplate, helmet and greaves, together with the sword and lance. The term is sometimes applied to a later date, "panoply" did not come into use till the end of the 16th and beginning of the 17th century, and was then used to describe the complete suits of plate-armour covering the whole body. The figurative use of the word is chiefly due to the phrase ἡ πανοραμα τῶν θεῶν, "the whole armour of God" (Eph. vi. 11).

PANORAMA (Gr. πανοράμα, all, and ὄραμα, view), the name given originally to a pictorial representation of the whole view visible from one point by an observer who in turning round looks successively to all points of the horizon. In an ordinary picture only a small part of the objects visible from one point is included, far less being generally given than the eye of the observer can take in whilst stationary. The drawing is in this case made by projecting the objects to be represented from the point occupied by the eye on a plane. If a greater part of a landscape has to be represented, it becomes more convenient for the artist to suppose himself surrounded by a cylindrical surface in whose centre he stands, and to project the landscape from this position on the cylinder. In a panorama such a cylinder, originally of about 60 ft., but now extending to upwards of 130 ft. diameter, is covered with an accurate representation in colours of a landscape, so that an observer standing in the centre of the cylinder sees the picture like an actual landscape in nature completely surround him in all directions. This gives an effect of great reality to the picture, which is skilfully aided in various ways. The observer stands on a platform representing, say, the flat roof of a house, and the space between this platform and the picture is covered with real objects which gradually blend into the picture itself. The picture is lighted from above, but a roof is spread over the central platform so that no light but that reflected from the picture reaches the eye. To make this light appear the more brilliant, the passages and staircases which lead the spectator to the platform are kept nearly dark. These panoramas, suggested by a German architectural painter named Breisig, were first executed by Robert Barker, an Edinburgh artist, who exhibited one in Edinburgh in 1788, representing a view of that city. A view of London and views of sea-fights and battles of the Napoleonic wars followed, Panoramas gained less favour on the continent of Europe, until, after the Franco-German War, a panorama of the siege of Paris was exhibited in Paris. Since then some notable panoramas have been on view in the cities of Europe and America.

The name panorama, or panoramic view, is also given to drawings of views from mountain peaks or other points of view, such as one in the guide-books to Switzerland and other mountainous districts. In photography a panoramic camera is one which enables a wide picture to be taken.

PANPSYCHISM (Gr. πνημίς, all; ψυχή, soul), a philosophical term applied to any theory of nature which recognizes the existence of a psychical element throughout the objective world. In such theories not only animals and plants but even the smallest particles of matter are regarded as having some rudimentary kind of sensation or "soul," which plays the same part in relation to their objective activities or modifications as the soul does in the case of human beings. Such theories are the modern scientific or semi-scientific counterparts of the primitive animism of savage races, and may be compared with the hylozoism of the Greek physicists. In modern times the chief exponents of panpsychist views are Thomas Carlyle, Fechner and Paulsen: a similar idea lay at the root of the physical theories of the Stoics.

PANSY, or HEARTSEASE. This flower has been so long cultivated that its source is a matter of uncertainty. As we now see it, it is purely artificial production, differing considerably from any wild plant known. It is generally supposed to be merely a cultivated form of Viola tricolor (see VIOLET), a cornfield weed, while others assert it to be the result of hybridization between V. tricolor and other species such as V. alata, V. grandiflora, &c. Some experiments of M. Carrière go to show that seeds of the wild V. tricolor will produce forms so like those of the cultivated pansy that it is reasonable to assume that that flower has originated from the wild plant by continuous selection. The changes that have been effected from the wild type are, however, more striking to the eye than really fundamental. Increase in size, an alteration in form, by virtue of which the narrow oblong petals are converted into circular ones, and variations in the intensity and distribution of the colour—these are the changes that have been wrought by continued selection, while the more essential parts of the flower have been relatively unaffected. The modern varieties of the pansy consist of the show varieties, and the fancy varieties, obtained from Belgium, and now very much improved. Show varieties are subdivided according to the colour of the flowers into selves, white grounds and yellow grounds. The fancy or Belgian pansies have various colours blended, and the petals are blotched, streaked or edged. The bedding varieties, known as violas or tufted pansies, have been raised by crossing the pale-blue Viola cornuta, and also V. lutea, with the show pansies. They are harder than the true pansies and are free-blooming sorts marked rather by effectiveness of colour in the mass than by quality in the individual flower; they are extremely useful in spring and summer flower-gardening.

The pansy flourishes in well enriched garden soil, in an open but cool situation, a loamy soil being preferable. Cow-dung is the best manure on a light soil. The established sorts are increased by cuttings, whilst seeds are soon to procure novelties. The cuttings, which should consist by preference of the smaller non-flowering growths from the base of the plant, may be inserted early in September, in sandy soil, under a light-hilt or in boxes under glass, and
as soon as rooted should be removed to a fresh bed of fine sandy soil. The seeds may be sown in July, August or September. The bed may be prepared early in September, to be in readiness for planting, by being well manured with cow-dung and trenched up to a depth of 2 ft. The plants should be planted in rows at about a foot apart. In spring they should be picked off and, when half-grown, pegging down process performed in a thorough manner, watering in dry weather, and keeping as cool as possible. Successional beds may be put in about February, the young plants being struck later, and wintered in cold frames. The fancy pansies require similar treatment, but are generally of a more vigorous constitution.

When grown in pots in a cold frame, about half a dozen shoots filling out a 6-in. pot, pansies are very handsome decorative objects. The cuttings should be struck early in August, and the plants shifted into their blooming-pots by the middle of October. A rich open loamy compost is necessary to success, and they must be kept free of aphides. Both the potted plants and those grown in the open beds benefit by the use of liquid manure.

**PANTAEUS**, head of the catechetical school at Alexandria, c. A.D. 180–200, known chiefly as having been the mentor of Clement, who succeeded him, and of Alexander, bishop of Jerusalem. Clement speaks of him as the "Sicilian bee," but of his birth and death nothing is known. Eusebius and Jerome speak of him as having been, originally at least, a Stoic, and having chanced, of being about this period, and being, as a missionary to "India." There is some reason to think that this means the Malabar coast. There was a considerable intercourse between south India and the east Mediterranean at the time, and Christian thought possibly did something to mould the great system of Tamil philosophy known as the *Saiv Siddhanta*. Panteenus "expounded the treasures of divine doctrine both orally and in writing," but only a few brief reminiscences of his teaching are extant (see Routh, *Rel. sac.* i. 375–383). Lightfoot suggests that the conclusion of the well-known Epistle to Diognetus, chs. 11, 12, may be the work of Panteenus. Clement thought highly of his abilities, and Origen appeals to his authority in connexion with the inclusion of philosophy in the theological course.

**PANTALOON** (Ital. pantalone), a character in the old Italian popular comedy, said to represent a Venetian, from the favourite Venetian saint San Pantalone, and transferred from it to pantomime (q.v.). The Italian pantalone was always a silly old man with spectacles and wearing slippers, and his character was maintained in pantomime and has also made his name a synonym for a dottering old man, as in Shakespeare's *As You Like It* (v. iii. 79). Or in the term (as in pantomine "pantaloons") whence "pants" has also been given to certain forms of garment for the legs, the exact meaning varying at different times.

**PANTECHNICON**, an invented word, from Gr. παντεχνη, all, and τέχνηδη, of or belonging to the arts (τέχνα), originally used as the name of a bazaar in which all kinds of artistic work was sold; it was established in Motcomb Street, Belgrave Square, London, early in the 19th century, but failed and was turned into a furniture depository, in which sense the word has now passed into general usage. The large vans used for removing furniture are hence known as pantechnic vans or pantechnicons simply.

**PANTELLERIA**, or **PANTALARIA** (ancient *Cossyra*?), an island in the Mediterranean, 62 m. S. by W. of the south-western extremity of Sicily, and 44 m. E. of the African coast, belonging to the Sicilian province of Trapani. Pop. (1901), 8683. It is entirely of volcanic origin, and about 45 sq. m. in area; the highest point, an extinct crater, is 2743 ft. above sea-level. Hot mineral springs and effusions of steam still testify to the presence of volcanic activity. The island is fertile, but lacks fresh water. The principal town (pop. about 4000) occupies the north-west corner of the island, and is the only harbour (only fit for small steamers), which is fortified. There is also a penal colony here. The island can be reached by steamer from Trapani, and lies close to the main route from east to west through the Mediterranean. In 1905 about 300,000 gallons of wine (mostly sweet wine), and 1900 tons of dried raisins, to the value of £34,720, were exported.

On the west coast, 2 m. south-east of the harbour, a necolithic village was situated, with a rampart of small blocks of obsidian about 25 ft. high, 9 ft. wide at the base, and 16 at the top, upon the undefended eastern side: within it remains of huts were found, with pottery, tools of obsidian, &c. The objects discovered are in the museum at Syracuse. To the south-east, in the district known as the Cuneile, are a large number of tombs, known as *sesi*, similar in character to the *nuraghi* of Sardinia, though of smaller size, consisting of round or elliptical towers with sepulchral chambers in them, built of rough blocks of lava. Fifty-seven of them can still be traced. The largest is an ellipse of about 60 by 66 ft., but most of the *sesi* have a diameter of 20–25 ft. only. The identical character of the pottery found in the *sesi* with that found in the prehistoric village proves that the former are the tombs of the inhabitants of the latter. This population came from Africa, not from Sicily, and was of Iberian or Ibero-Ligurian stock. After a considerable interval, during which the island probably remained uninhabited, the Carthaginians took possession of it (no doubt owing to its importance as a station on the way to Sicily) probably about the beginning of the 7th century B.C., occupying as their acropolis the twin hill of San Marco and Sta Teresa, r m. south of the town of Pantelleria, as the town of Trapani was then, and used it till 1123 as a Roman fort. Trapani, being the site of a great volcanic eruption, is now only a pile of ruins, with blocks of masonry, and also of a number of cisterns. Punic tombs have also been discovered, and the votive terra-cottas of a small sanctuary of the Punic period were found near the north coast.

The Romans occupied the island as the Fasti Triumphales record in 255 B.C., lost it again the next year, and recovered it in 277 B.C. Under the Empire it served as a place of banishment for prominent persons and members of the imperial family. The town enjoyed municipal rights. In 700 the Christian population was annihilated by the Arabs, from whom the island was taken in 1123 by Roger of Sicily. In 1317 a Spanish fleet, under the command of Requesens, won a considerable victory here, and his family became princes of Pantelleria until 1555, when the town was sacked by the Turks.

( T. As.)

**PANTHEISM** (Gr. πάν, all, θεός, god), the doctrine which identifies the universe with God, or God with the universe. The term "panteist" was apparently first used by John Toland in 1705, and it was at once adopted by French and English writers. The word is now used of the system of thought or attitude of mind for which it stands. It is a person who in the contemplation of the infinite (Brahma). In Greece the idea of a fundamental unity behind the plurality of的现象 was present, though vaguely, in the minds of the early physicists (see IONIAN SCHOOL), but the first thinker who focussed the problem clearly was Xenophanes. Unlike the Hindu, Xenophanes inclined to pantheism as a protest against the anthropomorphic polytheism of the time, which seemed to him improperly to exalt one of the many modes of finite existence into the place of the Infinite. Thus Xenophanes for the first time postulates a supreme God whose

1 Strictly, pantheism is to identify the universe with God, while the term "pancosmism" (πᾶν, κόσμος, the universe) has frequently been used for the identification of God with the universe. For practical purposes this refinement is of small value, the two ideas being aspects of the same thing: cf. A. M. Fairbairn, Studies in *Philos. Relig. Hist.* (1877), p. 362. Both "Atheism" (q.v.) and "Acosmism" are used as contradictorys.
characteristic is primarily the negation of the finite. A similar
metaphysics from a different starting-point is found in Heraclitus,
who posits behind the perpetually changing universe of
phenomena a One which remains. This attitude towards
existence, expressing itself in different phraseology, has been
prominent to a greater or less degree since Xenophanes and
Heraclitus. Thus the metaphysic of Plato finds reality only in
the "Idea," of which all phenomena are merely imperfect copies.
Neoplatonism (and especially Plotinus) adopted a similar attitude.
The Stoics, with the supreme object of giving to human
life a definite unity and purpose, made the individual a part of the
universe and sought to obliterate all differences. The
universe to them is a manifestation of divine reason, while all things
come from and return to (the ὑὸς ἄνω κάτω) the πνεῦμα διαπέρατο, the
ultimate matter. The same problems in a different context
confronted the monotheistic religions of Judaism and Christian-
ty. We find Philo Judaean endeavoring to free the concept
of the Old Testament Yahweh from anthropomorphic character-
istics and finite determinations. But though Philo sees the
difficulties of the orthodox Jew he cannot accept pantheism
or mysticism so far as to give up the personality of God (see
LOGOS).

With Neoplatonism we enter upon a somewhat different
though closely allied attitude of mind. To Plotinus God lies
beyond sense and imagination: all the theologian can do is to
point the way in which the thinker must travel. Though the
spirit and the language of Plotinus is closely allied to that of
pantheism, the result of his thinking is not pantheism but
mysticism. This may be briefly illustrated by a comparison
with the greatest of modern pantheists, Spinoza. To him God
is the immanent principle of the universe—"Deus sive Natura."
On the principle that everything which is determined (finite)
is "negated" ("determinato est negatio"), God, the ultimate
reality must be entirely undetermined. To explain the universe
Spinoza postulates a "thing in itself" or God, though undetermined
ab extra, is capable of infinite self-determination. Thus God,
the causa sui, manifests himself in an infinite multiplicity
of particular modes. Spinoza is, therefore, both pantheist and
pancospastist: God exists only as realized in the cosmos: the
universe exists only as a manifestation of God. Plotinus, on
the other hand, cannot admit any realization or manifestation
of the Infinite: God is necessarily above the world—he has
no attributes, and is unthinkable. Such a view is not pantheism
but mysticism (q.v.), and should be compared with the theology
of Oriental races.

The semi-Oriental mysticism of the Neoplatonists and the
Logos doctrines of the Stoics alike influence early Christian
doctrine, and the pantheistic view is found frequently in medieval
theology (e.g. in Eriugena, Meister Eckhardt, Jakob Boehme).
The Arabic scholar Averroes gave Aristotle to western Europe
in a pantheistic garb, and thus influenced medieval scientists.
So Bruno constructed a personified nature, and the scientific
and humanistic era began. The pantheism of Spinoza,
combining as it did the religious and the scientific points of view,
had a wide influence upon thought and culture. Schelling
(in his Identity-philosophy) and Hegel both carried on the
pantheistic tradition, which after Hegel broke up into two lines
of thought, the one pantheistic the other atheistic.

From the religious point of view there are two main problems.
The first is to establish any real relation between the individual
and God without destroying personality and with it the whole
idea of human responsibility and free will: the second is to
explain the infinity of God without destroying his personality.
In what sense can God be outside the world (see DEISM)? In
what sense (at pantheism)? The great objection to pantheism
is that, though ostensibly it magnifies the Creator and gets rid
of the difficult dualism of Creator and Creation, it tends prac-
tically to deny his existence in any practical intelligible sense.

See, further, THEISM; DEISM; ATHEISM; ABSOLUTE.

PANTHEON (Lat. pantheon or pantheon; Gr. πανθεῖον, all-
holy, from πᾶς, all, and θεός god), the name of two buildings in
Rome and Paris respectively; more generally, the name of any
building in which as a mark of honour the bodies of the nation's
famous men are buried, or "memorials" or monuments to them
are placed. Thus Westminster Abbey is sometimes styled the
British "Panthém," and the rotunda in the Escorial where
the kings of Spain are buried also bears the name. Near
Regensburg (q.v.) is the pantheon of German worthies, known
as the Valhalla. The first building to which the name was
given was that built in Rome in 27 B.C. by Agrippa; it was
burned later and the existing building was erected in the reign
of Hadrian; since a.d. 609 it has been a Christian church,
S Maria Rotunda. It was the Paris building that gave rise
to the generic use of the term for a building where a nation's
illustrious dead rest. The Pantheon in Paris was the church
built in the classical style by Soufflot; it was begun in 1764
and consecrated to the patroness of the city, Sainte Geneviève.
At the Revolution it was secularized under the name of Le
Panthéon, and dedicated to the great men of the nation. It
was reconstituted in 1885 for worship, was again secularized
in 1890, was once more a place of worship from 1891 to 1870,
and was then a third time secularized. On the entablature is
inscribed the words Aux Grands Hommes La Patrie Reconna-
sante. The decree of 1885 finally established the building for
the purpose for which the name now stands.

PANTHER, another name for the leopard (q.v.), also used in
America as the name of the puma (q.v.). The word is an adap-
tation of Lat. panthera; Gr. πάνθηρ, the supposed derivation of
which from πᾶς, all, and θηρι, animal, gave rise to many tales
and fables in medieval bestiaries and later scientific works.
The panther was supposed to be a distinct animal from the
pardus, pard, the leopard, to which also many legends were
attached. In modern times a distinction had been unscientific-
ly drawn between a larger type of leopard to which the name
panther was given, and a smaller and more graceful specimen.

The city of Seine, on the Canal d'Ourcq, adjoining the fortifications of Paris
on the north-east. Pop. (1906), 33,604. The manufacture
of boilers, railway wagons, machinery, oil, glass, chemicals,
polish and perfumery, and the operations of dye-works, foundries
and distilleries, represent some of the varied branches of its
industrial activity. There is also a state-manufactory
of tobacco.

PANTOGRAPH, or PANTOGRAPH (from the Greek πανθέον, all,
and γράφων, to write), an instrument for making a reduced, an
enlarged, or an exact copy of a plane figure.

In its commonest form it consists of two long arms, AB and AC
(Fig. 1), jointed together at A, and two short arms, FD and FE, jointed
together at F. With the long arms at D and E; FD is made
exactly equal to AE and FE to AD, so that ADPE is a parallelo-
gram whatever the lengths of AB and AC. The instrument is sup-
posed to be parallel to the paper on castors, on which it
moves freely. A tube is usually fixed vertically at e, near the
extremity of the long arms AB and AC, and similar tubes are mounted on plates
which slide along the short arms BD and FD; they are intended to hold either the axis pin on a
fulcrum round which the instrument turns, or a steel
pointer, or a pencil, interchangeably. When the centres of the tubes
are exactly in a straight line, as on the dotted line bf, the small
triangle bFD will always be similar to the large triangle bAC; and then,
if the fulcrum is placed under b, the pencil at f, and the pointer at e,
when the instrument is moved round the fulcrum as a pivot, the
point and the pointer will move parallel to each other through distances
which will be respectively in the proportion of b to bc; thus the pencil
and the pointer will be reduced, or increased, or traversed,
and the sliders set for f to bisect bc, the map would be copied exactly.
Lines are marked upon the arms BD and FD, and indications to the positions in which
the sliders must be set for the ratios $\frac{1}{2}$, $\frac{1}{3}$, ... which are commonly
required.

The square pantograph of Adrian Gavard consists of two graduated
arms which are pivoted on a plain bar and connected by a graduated
bar sliding between them throughout their entire length, to be set
PANTOMIME

at any required distance from the plain bar; a sliding plate carrying a vertical tube, to hold either the axle of the fulcrum, the pencil, or the pointer, is mounted on one of the arms and on a prolongation of the plain bar beyond the other arm, and also on the graduated connecting bar; and an additional arm is provided by means of which reductions below the enlargements above the scales given on the instrument can be readily effected.

The eidograph (Gr. eldos, form) is designed to supersede the panto- graph, which is somewhat unsuited for certain purposes. It consists of several graduated scales, one of which is held over a fulcrum and carries the others, which are lighter, one at each extremity. The three bars are movable from end to end in box-sockets, each having an index and graduated scale. The one in contact with the principal bar turns round the vertical axe of the fulcrum; that of each side bar is attached to a vertical axe, which also carries a grooved wheel of large diameter and turns in a collar at either end of the principal bar. The pencils are held by a band fitting tightly into the grooves, so that they always turn together through identical arcs; thus the side bars over which they are respectively mounted, when once set parallel, turn with them and always remain parallel. A pointer is held at the end of one of the side bars and a pencil at the diagonally opposite end of the other. The bars may be readily set by their graduated scales to positions in which the distances of the pencil and the pointer from the fulcrum are always in the ratio of the given and the required magnifications.

Numerous other modifications have been proposed from time to time; many forms are described in G. Fellehns Der Pantograph (Berlin, 1903).

PANTOMIME, a term which has been employed in different senses at different times in the history of the drama. Of the Roman pantomimus, a spectacular kind of play in which the functions of the actor were confined to gesticulation and dancing, while occasional music was sung by a chorus or behind the scenes, some account is given under Drama. In Roman usage the term was applied both to the actor of this kind of play and to the play itself; less logically, we also use the term to signify the method of the actor when confined to gesticulation. Historically speaking, so far as the Western drama is concerned there is no intrinsic difficulty between the Roman pantomimus and the modern "ballet of action," except that the latter is accompanied by instrumental music only, and that the personages appearing in it are not usually masked. The English "dummy-show," though fulfilling a special purpose of its own, was likewise in the true sense of the word pantomime.

The modern pantomime, as the word is still used, more especially in connexion with the English stage, signifies a dramatic entertainment in which the action is carried on with the help of spectacle, music and dancing, and in which the performance of a certain action or of its adjuncts is conducted by certain conventional characters, originally derived from Italian "masked comedy," itself an adaptation of the fabulæ Atellanaœ of ancient Italy. Were it not for this addition, it would be difficult to define modern pantomime so as to distinguish it from the masque; and the least rational of English dramatic species would have to be regarded as essentially identical with another to which English literature owes some of its choicest fruits. These early spectacles, as well as the modern williamtions which modern pantomime contains very speedily, though in varying proportions and manifold combinations, introduced themselves into the modern drama as it had been called into life by the Renaissance. In Italy the transition was almost imperceptible from the pastoral drama to the opera; on the Spanish stage ballets with allegorical figures and military spectacles were known towards the close of the 16th century; in France ballets were introduced in the days of Marie de' Medici, and the popularity of the opera was fully established in the earlier part of the reign of Louis XIV.

The history of these elements need not be pursued here, but there is a special ingredient in modern pantomime of which something more has to be said. From the latter part of the 16th century (Henry III. in 1596, sought to divert the drowsy states-general at Blois by means of the celebrated Italian company of the Gelosi) professional Italian comedy (commedia dell' arte, called commedia all' improvviso only because of the skill with which the schemes of its plays were filled up by improvisation) had found its way to Paris with its merry company of characters, partly corresponding to the favourite types of regular comedy both ancient and modern, but largely borrowed from the new species of masked comedy—so called from the new species being carried on by certain typical figures in masques—said to have been invented earlier in the same century by Angelo Beolco (Ruzzante) of Padua. These types, local in origin, included Pantalone the Venetian merchant, who survives in the uncommercial Pantalone, the Bolognese Dottore. The Zannis (Giovannis) were the domestic servants in this species of comedy, and included among other varieties the Arlecchino. This is by far the most interesting of these types, and by far the best discussed. The Arlecchino was formerly supposed to have been, like the rest, of Italian origin. The very remarkable contribution (cited below) of Dr Otto Driesen to the literature of folk-lore as well as to that of the stage seems however to establish the conclusion (to which earlier conjectures pointed) that the word Harlequin or Harlequin is of French origin, and that the dramatic figure of Harlequin is an evolution from the popular tradition of the harlekin-folk, which seems to have been based on the model of the famous Italian character of the same name, a character who was perhaps a native of Calabria. The "danced souls" of legend became the comic demons of later centuries, the croque-sots with the devil's mask; they left the impress of their likeness on the hell-mouth of the religious drama, but were gradually humanized as a favourite type of the Parisian popular street-masques (charivaris) of the 14th and 15th centuries. Italian literature contains only a single passage before the end of the 16th century which can be brought into any connexion with this type—the alichino (cat's back) of canto xxi. of the Inferno. The French harlequin was, however, easily adopted into the family of Italian comedy, where he may, like his costume, 1 have been associated with early national traditions, and where he continued to diverge from his father Zannis of the stolid sort, the Scapin of French comedy-farce. From the time of the performances in France of the celebrated Fedeli company, which played there at intervals from the beginning to the middle of the 17th century onwards, performing in a court ballet in 1636, Tristram Martinelli had been its harlequin, and the character thus preceded that of the Parisian favourite Trivelin, whose name Cardinal de Retz was fond of applying to Cardinal Mazarin. There can be no pretence here of pursuing the French harlequin through his later developments in the various species of the comic drama, including that of the marionettes, or of examining the history of his supersession by Pierrot and of his ultimate extinction.

Students of French comedy, and of Molière in particular, are aware of the influence of the Italian players upon the progress of French comedy, and upon the works of its incomparable master. In other countries, where the favourite types of Italian popular comedy had been less generally seen or were unknown, popular comic figures such as the English fools and clowns, the German Hanswurst, or the Dutch Pickelhering, were ready to renew themselves in any and every fashion which preserved to them the gross salt favoured by their patrons. Indeed, in Germany, where the term pantomime was not used, a rude form of dramatic buffoonery, corresponding to the coarser sides of the modern English species so-called, long flourished, and threw back for centuries the progress of the regular drama. The banishment of Hanswurst from the German stage was formally proclaimed by the famous actress Caroline Neuber at Leipzig in a play composed for the purpose in 1737. After being at last suppressed, it found a commendable substitute in the modern Zauberposse, the more genial Vienna counterpart of the Paris Ierie and the modern English extravaganza.

In England, where the masque was only quite exceptionally revived after the Restoration, the love of spectacle and other frivolous allusions was at first mainly met by the various forms of dramatic entertainment which went by the name of opera." In the preface to Albion and Albanius (1688), Dryden gives a definition of opera which would fairly apply to modern extravaganza, or to modern pantomime with the harlequinade.

1 The traditional costume of the ancient Roman mimmi included the centumaculis or variegated (harlequin’s) jacket, the shaven head, the sooty face and the unshod feet.
left out. Character-dancing was, however, at the same time largely introduced into regular comedy; and, as the theatres vied with one another in seeking quodcumque modo to gain the favour of the public, the English stage was fully prepared for the innovation which awaited it. Curiously enough, the long-lived but cumbersome growth called pantomime in England owes its immediate origin to the beginnings of a dramatic species which has artistically furnished congenial delight to nearly two centuries of Frenchmen. Of the early history of vaudeville it must here suffice to say that the unprivileged actors, at the fairs, who had borrowed some of the favourite character-types of Italian popular comedy, after eluding prohibitions against the use by them of dialogue and song, were at last allowed to set up a comic opera of their own. About the second quarter of the 18th century, before these performers were incorporated with the Italians, the light kind of dramatic entertainment combining pantomime proper with dialogue and song enjoyed high favour with the French and their visitors during this period of peace. The vaudeville was cultivated by Le Sage and other writers of mark, though it did not conquer an enduring place in dramatic literature till rather later, when it had, moreover, been completely nationalized by the extension of the Italian types.

It was this popular species of entertainment which, under the name of pantomime, was transplanted to England before the next five years. But it had attained to any fixed form, or could claim any of its productions and place in dramatic literature. Colley Cibber mentions, as the first example, followed by "that Succession of monstrous Mollies," a piece on the story of Mars and Venus, which was still in doubt; for he describes it as "form'd into a connected Presentation of Dances in Character, wherein the Passions were so happily expressed, and the whole Story so intelligibly told, by a mute Narration of Gesture only, that even thinking Spectators allow'd it both a pleasing and a rational Entertainment." There is nothing to show that Harlequin and his companions figured in this piece. Genet, who has no record of it, dates the period when such entertainments first came into vogue in England about 1723. In that year the pantomime of Harlequin Dr Faustus had been produced at Drury Lane—it's author being John Thurmond, a dancing master, who afterwards (in 1727) published a grotesque entertainment called The Miser, or Wagner and Abercrombie (a copy of this is in the Dyce Library). Hereupon, in December 1723, John Rich (1692–1761), then lessee of the theatre in Lincoln's Inn Fields, produced there as a rival pantomime The Necromancer, or History of Dr Faustus, no doubt, says Genet, "gotten up with superior splendour." He had as early as 1717 been connected with the production of PANTOMIME [PANTOMIME] Harlequin Executed, and there were instances of similar entertainments as far back as the year 1700. But it was the insipid influence of French example and the keen rivalry between the London houses, which in 1723 really established pantomime on the English stage. Rich was at the time fighting a difficult battle against Drury Lane, and his pantomimes at Lincoln's Inn Fields, and afterwards at Covent Garden, were extraordinarily successful. He was himself an inimitable harlequin, and from Garrick's lines in his honour it appears that his acting consisted of "frolic gestures" without words. The favourite Drury Lane harlequin was Pinkethman (Pope's "poor Pinky"); readers of the Tatler (No. 188) will remember the iridescent nicety with which his merits are weighed against those of his competitor Bullock at the other house. Colley Cibber, when described by Pope as "mounting the wind on grinning dragons" briskly denied having in his own person or otherwise encouraged such buffoons; in his Apology, however, he enters into an elaborate defence of himself for having allowed himself to be forced into countenancing the "gin-shops of the stage," pleading that he was justified by necessity, as Henry IV. was in changing his religion. Another butt of Pope's, Lewis Theobald, was himself the author of more than one pantomime; their titles already run in the familiar fashion, e.g. A Dramatic Entertainment, call'd Harlequin a Sorcerer, with the Loves of Pluto and Proserpine (1725); the "book of the words," as it may be called, is in the Dyce Library. The other early pantomime (also in the Dyce Library) called Persus and Andromeda, with the Rape of Colombine, or The Flying Lovers, there are five intermedi, three serious and two comic. This is precisely in the manner of Fielding's dramatic sequel against pantomimes, Tumble-down Dick, or Phaeton in the Suds, first acted in 1744, and ironically dedicated to "Mr John Lun," the name that Rich chose to assume as harlequin. It is a capital bit of burlesque, which seems to have been directly suggested by Pritchard's Fall of Phaeton, produced in 1736.

There seems no need to pursue further the history of English pantomime in detail. "Things of this nature are above criticism," as Mr Machine, the "composer" of Phaeton, says in Fielding's piece. The attempt was made more than once to free the stage from the incubus of entertainments to which the public persisted in flocking; in vain Colley Cibber at first laid down the rule of never giving a pantomime together with a good play; in vain his son Theophilus after him advised the return of part of the entrance money to those who would leave the house before the pantomime began. "It may be questioned," says the chronicler, "if there was a demand for the return of £20 in ten years." Pantomime carried everything before it when there were several theatres in London, and a dearth of high dramatic talent prevailed in all; and, allowing for occasional counter-attractions of a not very dissimilar nature, pantomime continued to flourish after the Licensing Act of 1737 had restricted the number of London play-houses, and after Garrick's star had risen on the theatrical horizon. He was himself obliged to satisfy the public appetite, and to disoblige the admirers of his art, in deference to the drama's most imperious patrons—the public at large.

In France an attempt was made by Noverre (q.v. to restore pantomime proper to the stage as an independent species, by treating mythological subjects seriously in artificial ballets. This attempt, which of course could not prove permanently successful, met in England also with great applause. In an anonymous tract of the year 1780 in the Dyce Library, attributed by Dyce to Archdeacon Nares (the author of the Glossary), Noverre's pantomime or ballet Cupid and Psyche is commended as of very extraordinary merit in the choice and execution of the subject. It seems to have been without words. The writer of the tract states that "very lately the serious pantomime has made a new advance in this country, and has gained establishment in an English theatre"; but he leaves it an open question whether the grand ballet of Medea and Jason (apparently produced a few years earlier, for a burlesque on the subject came out in Covent Garden, the piece quite popular, and the pantomime was performed in London, and after Garrick's star had risen on the theatrical horizon. He was himself obliged to satisfy the public appetite, and to disoblige the admirers of his art, in deference to the drama's most imperious patrons—the public at large.

To conclude, the chief difference between the earlier and later forms of English pantomime seems to lie in the fact that in the earlier Harlequin prevailed the action, appearing in the comic scenes which alternated throughout the piece with the serious which formed the backbone of the story. Columbine (originally in Italian comedy Harlequin's daughter) was generally a village maiden courted by her adventurous lover, whom village constables pursued, thus performing the laborious part of the policeman of the modern harlequind. The brilliant scenic effects were of course accumulated, instead of upon the transformation scene, upon the last scene of all, which in modern pantomime follows upon the shadowy chase of the characters called the rally. The commanding influence of the clown, to whom pantaloon is attached as friend, flatterer and foil, seems to be of comparatively modern growth; the most famous of his craft was undoubtedly Joseph Grimaldi (1779–1837). His memory is above all connected with the famous pantomime of Mother Goose, produced at Covent Garden in 1806. The older British stage of Christmas pantomime, which kept its place in London till the 'seventies, has been preserved from oblivion in Thackeray's Sketches and Travels in London. The species is not yet wholly extinct; but, by degrees, the rise of the music-halls and the
PANTÓN—PAOLI, P.

popularity of a new type of music-hall performer influenced the character of the show which was given under the name of a Christmas pantomime at the theatres, and it became more of a burlesque "variety entertainment," dovetailed into a fairy play and with the "harlequinade" part (which had formed the closing scene of the older sort) sometimes omitted. The word had really lost its meaning. The thing itself survived rather in such occasional appearances as the Pierrot "drama without words," as seen among London players in the early nineties in such pieces as L'Enfant prodigue.

PANTÓN, a town of north-western Spain, in the province of Lugo; in a mountainous district, watered by the rivers Miño and Cabe. Pop. (1900), 12,088. Livestock is extensively reared, and large quantities of wheat, wine, oats and potatoes are produced. The other industries are distilling and linen manufacture. The nearest railway station is 6 m. east, at Montforte.

PANTRY (O. Fr. panellerie; Med. Lat. panetaria, a bread-shop, from panis, bread), originally a room in a house used for the storage of bread, hence "pantry" or "panter," an officer of a household in charge of the bread and stores. In the royal house of England the office was merged in that of butler. At coronations the office of "panter" was held by the lord of the manor of Kibworth Beauchamp; it was his duty to carry the salt-cellar and carving-knives to the royal table, and he kept these as his fee. The last holder of the office was Ambrose Dudley, son of John, duke of Northumberland, at Elizabeth's coronation. At his death the manor reverted to the Crown. "Pantry" was early widened in meaning to include a room in a house used for the storing of all kinds of food, and is now restricted to the butler's or parlourmaid's room, where plate, china, glass, &c., for the use of the table is kept, and duties in connexion with the serving of the table are performed.

PANTUN (Pantoom), a form of verse of Malay origin. An imitation of the form has been adopted in French and also in English verse, where it is known as "pantoum." The Malay pantun is a quatrain, the first and third and the second and fourth lines of which rhyme. The peculiarity of the verse-form resides in the fact that the first two lines have as a rule no actual connexion, in so far as meaning is concerned, with the last, or with one another. It is the reason d'ètre a means of supplying rhymes for the concluding lines. For instance—

Sindhádu kauy di-rimba
Benháng káraí bir-simpul páléh
Sángkoh dódak ber-isidék lúa,
Jángan di-káráp kata-káñ báléh.

The rhododendron is a wood of the jungle,
The strings within the frame-work of the loom are in a tangled knot.
It is true that I sit on thy lap,
But do not therefore cherish the hope that thou canst take any other liberty.

Here, it will be seen, the first two lines have no meaning, though according to the Malay mind, on occasion, these "rhyme-making" lines are held to contain some obscure, symbolical reference to those which follow them. The Malay is not exacting with regard to the correctness of his rhymes, and to his ear rimba and riba rhyme as exactly as pâleh and báléh. It should also be noted that in the above example, as is not infrequently the case with the Malay pantun, there is a similar attempt at rhyme between the initial words of the lines as well as between the word with which they conclude, sindhâd and sínggoh, benhâng and jângan, and káráp and káráp all rhyming to the Malayan end. There are large numbers of well-known pantuns with which practically all Malays are acquainted, much as the commoner proverbs are familiar to us all, and it is not an infrequent practice in conversation for the first line of a pantun—viz.: one of the two lines to which no real meaning attaches—to be quoted alone, the audience being supposed to possess the necessary knowledge to fit on the remaining lines for himself and thus to discover the significance of the allusion. Among cultured Malays, more especially those living in the neighbourhood of the raja's court, new pantuns are constantly being composed, many of them being of a highly topical character, and these improvisations are quoted from man to man until they become current like the old, well-known verses, though within a far more restricted area. Often too, the pantun is used in love-making, but they are then usually composed for the exclusive use of the author and for the delectation of his lady-loves, and do not find their way into the public stock of verses. "Capping" a pantun is also a not uncommon pastime, and many Malays will continue such contests for hours without once repeating the same verse, and often improvising quatrains when their stock threatens to become exhausted. When this game is played by skilled versifiers, the pantun last quoted, and very frequently the second line thereof, is used as the tag on to which to hang the succeeding verse.

The "pantoum" as a form of verse was introduced into French by Victor Hugo in Les Orientales (1829). It was also practised by Théodore de Banville and Lecomte de Lisle. Austin Dobson's In Town is an example of its use, in a lighter manner, in English. In the French and English imitation the verse form is in four-line stanzas, the second and fourth line of each verse forming the first and third of the next, and so on to the last stanza, where the first and third line of the first stanza form the second and fourth line.

PANYASIS (more correctly, Panyassis), of Halicarnassus, Greek epic poet, uncle or cousin of Herodotus, flourished about 470 B.C. He was put to death by the tyrant Lygdamis (c. 454). His chief poems were the Heroi eis 74 books, describing the adventures of Heracles in various parts of the world, and the Ionica in elegiacs, giving an account of the founding and settlement of the Ionian colonies in Asia Minor. Although not much esteemed in his own time, which was unapproachable to epic poetry, he was highly thought of by later critics, some of whom assigned him the next place to Homer (see Quintilian, Inst. oral. x. 1. 54). The few extant fragments show beauty and fullness of expression, and harmonious rhythm.

In fragments in G. Kinkel, Episc. poet. fragmenta (1877), ed. separately by J. F. Tschirner (1842); F. F. Funcke, De Panyasidis vita (1837); F. Krause, De Panyaside (1841).

PAOLI, CESARE (1840-1902), Italian historian and palaeographer, son of senator Balsassare Paoli, was born and educated in Florence. At the age of twenty-one he was given an appointment in the record office of his native city; from 1865 to 1871 he was attached to the Archives of Sienna, but eventually returned to Florence. In 1874 he was appointed first professor of palaeography and diplomas at the Istituto di Studi Superiori in Florence, where he continued to work at the interpretation of MSS. In 1887 he became editor of the Archivio storico italiano, to which he himself contributed numerous articles. His works consist of a large number of historical essays, studies on palaeography, transcriptions of state and other papers, reviews, &c.

PAOLI PASQUALE (1752-1827), Corsican general and patriot, was born at Stretta in the parish of Rostino. He was the son of Giacinto Paoli, who had led the Corsican rebels against Genoese tyranny. Pasquale followed his father into exile,
serving with distinction in the Neapolitan army; on his return to Corsica (q.v.) he was chosen commander-in-chief of the rebel forces, and after a series of successful actions he drove the Genoese from the whole island except a few coast towns. He then set to work to reorganize the government, introducing many useful reforms, and he founded a university at Corte. In 1765 he wrested the island of Corsica from the Genoese, who, despairing of ever being able to subjugate Corsica, again sold their rights over it to France. For two years Paoli fought desperately against the new invaders, until in 1769 he was defeated by vastly superior forces under Count de Vaux, and obliged to take refuge in England. In 1789 he went to Paris with the permission of the constituent assembly, and was afterwards sent back to Corsica with the rank of lieutenant-general. Disgusted with the excesses of the revolutionary government and having been accused of treason by the Convention, he summoned a consulta, or assembly, at Corte in 1793, with himself as president and formally seceded from France. He then offered the suzerainty of the island to the British government, but finding no support in that quarter, he was forced to go into exile once more, and Corsica became a French department. He retired to London in 1796, when he obtained a pension; he died on the 5th of February 1807.

See Boswell's Life of Johnson, and his Account of Corsica and Memoirs of P. Paoli (1768); N. Tommaseo, "Lettere di Pasquale de Paoli" (third edition, 1849), Corsica, &c. (ibid., nova serie, vol. xi., part ii.); Pompei, De L'état de la Corse (Paris, 1821); Giovanni Livi, "Lettere inedito di Pasquale Paoli" (in Arch. stor. ital., 5th series, vol. v. and vi.); Bartoli, Historia di Pasquale Paoli (Bastia, 1819); Lecuina, P. Paoli e la guerra d'indépen-
denza della Corsica (Milano, 1890); and Comte di Baturufo, Frag-ments pour servir à l'histoire de la Corse de 1764 à 1799 (Bastia, 1895).

PAPACY (1) a term formed on the analogy of "abacy" from Lat. papa, pope; cf. Fr. papeâtre on the analogy of royaume. Florence of Worcester, A.D. 1044, quoted by Du Cange s.v. Pâpa, has the Latin term papata; the New Eng. Dict. quotes Gower, Conf. i. 238, as the earliest instance of the word Papacie), the name most commonly applied to the office and position of the bishop or pope of Rome, in respect both of the ecclesiastical and temporal authority claimed by him, i.e. as successor of St. Peter and Vicar of Christ, over the Catholic Church, and as sovereign of the former papal states. (See Pope and Roman Catholic Church.)

I.—From the Origins to 1087.

The Christian community at Rome, founded, apparently, in the time of the emperor Claudius (41–54), at once assumed great importance, as is clearly attested by the Epistle to the Romans (58). It received later the visit of Paul while a prisoner, and, according to a tradition which is now but little disputed, that of the apostle Peter. Peter died there, in 64, without doubt, among the Christians whom Nero had put to death as guilty of the burning of Rome. Paul's career was also terminated at Rome by martyrdom. Other places had been honoured by the presence and preaching of these great leaders of new-born Christianity; but it is at Rome that they had borne witness to the Gospel by the shedding of their blood; there they were buried, and their tombs were known and honored. These facts rendered the Roman Church in the highest degree sacred. About the time that Peter and Paul died in Rome the primitive centre of Christianity—that is to say, Jerusalem—was disappearing amidst the disaster of the war of the Roman Empire with the Jews. Moreover, the Church of Jerusalem, narrowed by Jewish Christian particularism, was hardly qualified to remain the metropolis of Christianity, which was gradually gaining ground in the Graeco-Roman world. The true centre of this world was the capital of the Empire; the transference was consequently accepted as natural at an early date. The idea that the Roman Church is at the head of the other Churches, and has towards them certain duties consequent on this position, is expressed in various ways, with more or less clearness, in writings such as those of Clemens Romanus, Ignatius of Antioch and Hermas. In the 2nd century all Christendom looked to Rome; there was a constant stream of people—bishops from distant parts, apologists or heresiarchs. All that was done or taught in Rome was immediately echoed through all the other Churches; Irenaeus and Tertullian constantly lay stress upon the traditions of the Roman Church, which in those very early days was almost without rivals, save in Asia, where there were a number of flourishing Churches, also apostolic in origin, forming a compact group and conscious of their dignity. The great reception given to Polycarp on his visit to Rome in A.D. 155 and the attitude of St Irenaeus show that on the whole the traditions of Rome and of Asia harmonized quite well. They came into conflict, however (c. A.D. 190), on the question of the celebration of the festival of Easter. The bishop of Rome, Victor, desired his colleagues in the various parts of the Empire to form themselves into councils to inquire into this matter. Early Authority of the Roman Bishops. The invitation was accepted by all; and, the consultation resulting in favour of the Roman usage, Victor thought fit to exclude the recalcitrant Churches of Asia from the Catholic communion. His conduct in this dispute, though its severity may have been open to criticism, indicates a very definite conception on his part of his authority over the universal Church. In the 3rd century the same position was maintained, and the heads of the Roman Church continued to speak with the greatest authority. We find cases of their intervention in the ecclesiastical affairs of Alexandria, of the East, of Africa, Gaul and Spain. Though the manner in which they wielded their authority sometimes meets with criticism (Irenaeus, Cyprian, Firmilianus), the principle of it is never questioned. However, as time went on, certain Churches became powerful centres of Christianity, and even when they did not come into conflict with her, their very existence tended to diminish the prestige of the Roman Church.

After the period of the persecutions had passed by, the great ecclesiastical capitals Carthage, Alexandria, Antioch and Constantinople, as secondary centres of organization and Centrifugal Forces in the Catholic Church. administration, drew to themselves and kept in their hands a share in ecclesiastical affairs. It was only under quite exceptional circumstances that any need was felt for oecumenical decisions. Further, the direction of affairs, both ordinary and extraordinary, tended to pass from the bishops to the state, which was now Christianized. The Eastern Church had soon de facto as its head the Eastern emperors. Henceforth it receded more and more from the influence of the Roman Church, and this centrifugal movement was greatly helped by the fact that the Roman Church, having ceased to know the Greek language, found herself practically excluded from the world of Greek Christianity.

In the West also centrifugal forces made themselves felt. After Cyprian the African episcopate, in proportion as it perfected its organization, seemed to feel less and less the need for close relations with the apostolic see. In the 4th century the Donatist party was in open schism; the orthodox party had the upper hand in the time of Aurelius and Augustine; the regular meeting of the councils further increased the corporate cohesion of the African Episcopalian body. From them sprang a code of ecclesiastical laws and a whole judicial organization. With this organization, under the popes Zosimus, Boniface and Cele-istine the Roman Church came into conflict on somewhat trivial grounds, and was, on the whole, being worsted in the struggle, when the Vandal invasion of Africa took place, and for nearly a century to come the Catholic communities were subjected to very hard treatment. The revival which took place under Byzantine rule (6th and 7th centuries) was of little importance;
but the autonomy which had been denied them under Aurelius was maintained to the end, that is to say, until the Mahomedan conquest.

During the 4th century it is to be noticed that, generally speaking, the Roman Church played a comparatively insignificant part in the West. From the time of popes Damasus and Siricius various affairs were referred to Rome from Africa, Spain or Gaul. The popes were asked to give decisions, and in answer to those demands drew up their first decreals. However, side by side with the Roman see was that of Milan, which was also the capital of the Western Empire. From time to time it seemed as if Milan would become to Rome what Constantinople was to Alexandria. However, any danger that menaced the prestige of Rome disappeared when the emperor Honorius removed the imperial residence to Ravenna, and still more so when the Western emperors were replaced in the north of Italy by barbarian sovereigns, who were Arians.

In Spain, Gaul, Brittany and the provinces of the Danube, similar political changes took place. When orthodox Christianity had gained the upper hand beyond the Alps and the Pyrenees, the episcopate of those countries grouped itself, as it had done in the East, around the residence of the emperor. Thus Spain was produced a fairly strong centralization around the Visigothic king and the metropolitan of Toledo. In Gaul there was no chief metropolitan; but the king's court became, even sooner than that of Spain, the centre of episcopal affairs. The Britons and Irish, whose remoteness made them free from restriction, developed still more decided individuality. In short, the workings of all the Western episcopates, from Africa to the ocean, the Rhine and the Danube, lay outside the ordinary influence of the Roman see. All of them, even down to the metropolitan sees of Milan and Aquileia, practised a certain degree of autonomy, and in the 6th century this developed into what is called the Schism of the Three Chapters. With the exception of this schism, these episcopates were by no means in opposition to the Holy See. They always kept up relations of some kind, especially by means of pilgrimages, and it was admitted that in any disputes which might arise with the Eastern Church the pope had the right to speak as representative of the whole of the Western Church. He was, moreover, the only bishop of a great council that had not absolutely ceased to count—who was at that time a subject of the Roman emperor himself.

This was the situation when St Gregory was elected pope in 590. We may add that in peninsular Italy, which was most clearly under his ecclesiastical jurisdiction, the Lombards had spread havoc and ruin; as that nearly ninety bishoprics had been suppressed, either temporarily or definitively. The pope could act directly only on the bishoprics of the coast districts or the islands. Beyond this limited circle he had to act by means of diplomatic channels, through the governments of the Lombards, Franks and Visigoths. On the Byzantine side his hands were less tied; but here he had to reckon with the theory of the five patriarchates which had been a force since Justinian. According to Byzantine ideas, the Church was governed—under the supreme authority, of course, of the emperor—by the five patriarchs of Rome, Constantinople, Alexandria, Antioch and Jerusalem. Rome had for a long time opposed this division, but, since some kind of division was necessary, had put forward the idea of the three sees of St Peter—Rome, Alexandria and Antioch—of Constantinople and Jerusalem being set aside, as resulting from the schism of Christendom and which were just the most important; in fact the only ones which counted at all, since the monophysite secession had reduced the number of the orthodox in Syria and Egypt practically to nothing. This dissuasion was complete, and by actually suppressing the patriarchate of Jerusalem to reduce Byzantine Christendom to the two patriarchates of Rome and Constantinople.

There was no comparison between the two from the point of view of the East. The new Rome, where the emperor reigned, prevailed over the old, which was practically abandoned to the barbarians. She was still by courtesy given the precedence, but that was all; the council in Trullo (692) even claimed to impose reforms on her. When Rome, abandoned by the Eastern emperors, was placed under the protection of the Franks (754), relations between her and the Greek Church became gradually more rare. The chief occasions being the question of the images in the 8th century, the quarrel between Photius and Ignatius in the 9th, the affairs of the four marriages of the emperor Leo VI, and of the patriarch Theophylact in the 10th. On these different occasions the pope, ignored in ordinary times, was made use of by the Byzantine government to ratify measures which it had found necessary to adopt in opposition to the opinion of the Greek episcopate.

These relations were obviously very different from those which had been observed originally, and it would be an injustice to the Roman Church to take them as typical of her relations with other Christian bodies. She had done all she could to defend her former position. Toward the end of the 4th century, when southern Illyricum (Macedonia, Greece, Crete) was passing under the authority of the Eastern emperor, she tried to keep him within her ecclesiastical obedience by creating the vicariate of Thessalonica. Pope Zosimus (417) made trial of a similar organization in the hope of attaching the churches of the Gauls more closely to him by subscriptions in his name, and by the sending of answers to the papal decretals. But the result was not what he had expected. From the 6th century onwards the apostolic vicars of Arles and Thessalonica were merely the titular holders of pontifical honours, with no real authority over those who were nominally under their jurisdiction.

It was Gregory I. who, though with no premeditated intention, was the first to break this circle of autonomous or dissident Churches which was restricting the influence of the apostolic see. As the result of the missions sent to England by him and his successors there arose a church which, in spite of certain Irish elements, was and remained Roman in origin, and, above all, spirit and tendency. It was the old tradition of culture and religious learning imported from Rome, where they had almost ceased to bear any fruit, and by their aid enlightenment was carried to the Continent, to decadent Gaul and barbarian Germany. The great enthusiasm for the Church of England, which, founded, far from all traditions of autonomy by Roman legates, tended their obedience voluntarily. In Gaul there was no hostility to the Holy See, but on the contrary a profound veneration for the great Christian sanctuary of the West. The Carolingian princes, when Boniface pointed them towards Rome, followed him without their clergy offering any resistance on grounds of principle. The question of reform having arisen, from the apostolic see alone could its fulfilment be expected, since in it, with the succession of St Peter, were preserved the most august traditions of Christianity.

The surprising thing is that, although Rome was then included within the empire of the Franks, so that the popes were afforded special opportunities for activity, they showed for the most part no eagerness to strengthen their authority over the clergy beyond the Alps. Appeals and other matters of detail were referred to them more often than under the Merovingians. They gave answers to such questions as were submitted to them; and the machinery moved when set in motion from outside; but the popes did not attempt to interfere on their own initiative. The Franks, which was directed under the own initiative of Childebert II and Charlemagne and Louis the Pious. When this failure, as happened during the wars and partitions which followed the death of Louis, the fate of this Church, with no effective head and under no regular direction, was very uncertain. It was then that a clerk who saw that there was but an uncertain prospect of help from the pope of his time, conceived the shrewd idea of appealing to the popes of the past, so as to exhort the contemporary generation through the mouth of former popes, from Clement to Gregory. This design was
realized in the celebrated forgery known as the "False Decretals" (see Decretals).

Hardly were they in circulation throughout the Frankish Empire when it happened that a pope, Nicholas I, was elected who was animated by the same spirit as that which had inspired them. There was no lack of opportunities for intervening in the affairs not only of the Western but of the Eastern Church, and he seized upon them with great decision. He staunchly supported the patriarch Ignatius against his rival, Photius, at Constantinople; he upheld the rights of Teutberga, who had been repudiated by her husband, Lothair II, of Lorraine, against that prince and his brother, the emperor Louis II; and he combated Hincmar, the powerful metropolitan of Reims. It was in the course of this last dispute that the False Decretals found their way to Rome. Nicholas received them with some reserve; he refrained from giving them his sanction, and only borrowed from them what they had already borrowed from authentic texts, but in general he took up the same attitude as the forger had ascribed to his remote predecessors. The language of his successors, Andrius I and John VIII, still shows some trace of the energy and pride of Nicholas. But the circumstances were becoming difficult. Europe was being split up under the influence of feudalism; Christendom was assailed by the barbarians, Norsemen, Saracens and Huns; at Rome the papacy was passing into the power of the local aristocracy, with whom after Otto I. it was disputed from time to time by the sovereigns of Germany. It was still being held in strict subjection by the latter when, towards the end of the 11th century, Hildebrand (Gregory VII.) undertook its enfranchisement and began the war of the investitures (g.v.), from which the papacy was to issue with such an extraordinary renewal of its vitality.

In Eastern Christendom the papacy was at this period an almost forgotten institution, whose pretensions were always met by the combined opposition of the imperial authority, which still maintained Constantinople, and the Byzantine Church, and the authority of the patriarch of Constantinople, around which centred all that survived of Christianity in those regions. To complete the situation, a formal rupture had occurred in 1054 between the patriarch Michael Cerullarius and Pope Leo IX.

In the West, Rome and her sanctuaries had always been held in the highest veneration, and the pilgrimage to Rome was still the most important in the West. The pope, as officiating in these hallowed places, was as guardian of the tombs of St Peter and St Paul, and the inheritor of their rank, their rights, and their traditions, was the greatest ecclesiastical figure and the highest religious authority in the West. The greatest princes bowed before him; it was he who consecrated the emperor. In virtue of the spurious donation of Constantine, forged at Rome in the time of Charlemagne, which had at first circulated in obscurity, and was only gained universal credit, it was believed that the first Christian emperor, in withdrawing to Constantinople, had bestowed on the pope all the provinces of the Western Empire, and that in consequence all sovereignty in the West, even that of the emperor, was derived from pontifical concessions. From all points of view, both religious and political, the pope was thus the greatest man of the West, the ideal head of all Christendom.

When it was necessary to account for this position, theologians quoted the text of the Gospels, where St Peter is represented as the rock on which the Church is built, the pastor of the sheep and lambs of the Lord, the doorkeeper of the kingdom of heaven. The statements made in the New Testament about St Peter were applied without hesitation to all the popes, considered as his successors, the inheritors of his see (Petri sedis) and of all his prerogatives. This idea, moreover, that the bishops of Rome were the successors of St Peter was expressed very early—as far back as the 2nd century. Whatever may be said as to its historical value, it symbolizes very well the great authority of the Roman Church in the early days of Christianity; an authority which was then administered by the bishops of Rome, and came to be more and more identified with them. The councils were also quoted, and especially that of Nicaea, which does not itself mention the question, but certain texts of which contained the famous gloss: "Ecclesia Romana semper habuit primatum." But this proof was rather insufficient, as indeed it was felt to be, and, in any case, nothing could be deduced from it save a kind of precedence in honour, which was never contested even by the Greeks. The Gospel and unbroken tradition offered a better argument.

In his capacity as head of the church, "and president of the Christian agape," as St Ignatius of Antioch would have said, the pope was considered to be the supreme president and moderator of the oecumencical assemblies. When the episcopate met in council the bishop of Rome had to be at its head. No decisions of a general nature, whether dogmatic or disciplinary, could be made without his consent. The appeal from all patriarchal or conciliar judgments was to him; and on those occasions when he had to depose bishops of the highest standing, notably those of Alexandria and Constantinople, his judgments were carried into effect. During the religious struggles between the East and West he was on a few occasions condemned (by the Eastern council of Sardica, by Dioscorus, by Photius); but the sentences were not carried out, and were even, as in the case of Dioscorus, considered and punished as sacrilegious attacks. In the West the principle, "prima sedes a nemine judicatur," was always recognized and applied.

In ordinary practice this theoretically wide authority had only a limited application. The apostolic see harder ever interfered in the government of the local Churches. Practical save in its own metropolitan province, it took no part in the nomination of bishops; the provincial or regional councils were held without its authorization; their judgments and regulations were carried out without any suggestion that they should be ratified by Rome. It is only after the False Decretals that we meet with the idea that a bishop cannot be deposed and his place filled without the consent of the pope. And it should be noticed that this idea was put forward, not by the pope, but by the opinion of the Church with a view to defending the bishops against unjust sentences, and especially those inspired by the secular authority.

It was admitted, however, throughout the whole Church that the Holy See had an appellate jurisdiction, and recourse was had to it on occasion. At the council of Sardica (431) an attempt had been made to regulate the procedure in these appeals, by recognizing as the right of the pope the reversing of judgments, and the appointment of fresh judges. In practice, appeals to the pope, when they involved the annulling of a judgment, were judged by the pope in person.

But the intervention of the Holy See in the ecclesiastical affairs of the West, was of course of the Decretals, was only of a limited, sporadic and occasional nature. Nothing could have been more removed from a centralized administration than the condition in which matters stood with regard to this point. The pope was the head of the Church, but he exercised his authority only intermittently. When he did exercise it, it was far more frequently at the request of bishops or princes, or of the faithful, than of his own initiative. Nor had any administrative body for the supreme government of the Church ever been organized.

The old Roman clergy, the deacons and priests of the church at Rome (presbyteri incardinati, cardinales) formed the pope's council, and when necessary his tribunal; to them were usually added the bishops of the neighbourhood. The body of ecclesiastical notaries served as the staff of the chancery.

The Roman Church had from a very early date possessed considerable wealth. Long before Constantine we find her employing it in aid of the most distant churches. But her dispositions of property, confiscated under Diocletian, were restored of the Holy by Constantine, and since then had been continually See increased by gifts and bequests. In the 4th and 5th centuries,
the Roman Church possessed property in all parts of the empire, but gradually, whether because the confiscations of the barbarian emperors had curtailed its extent, or because the popes had made efforts to concentrate it nearer to themselves, the property of the Holy See came to be confined almost entirely to Italy. In the time of St Gregory there subsisted only what lay in Byzantine Italy, the Lombards having confiscated the property of the Church as well as the imperial domains. During the quarrels between the papacy and the Byzantine Empire her domains in lower Italy and Sicily also disappeared as time went on, and the territorial possessions of the Roman Church were concentrated in the neighbourhood of Rome.

It was then, towards the middle of the 8th century, that the pope, who already exercised a great influence over the government of the city and province of Rome, defending her peacefully and with difficulty against the advancing Lombard conquests, saw that he was forced, short of the protection of the Greek Empire, to put himself under the protection of the Frankish princes. Thus there arose a kind of sovereignty, disputed, it is true, by Constantinople, but which succeeded in maintaining itself. Rome, together with such of the Byzantine territories as still subsisted in her neighbourhood, was considered as a domain sacred to the apostle Peter, and entrusted to the administration of his successor, the pope. To it were added the exarchate of Ravenna and a few other districts of central Italy, which had been recently conquered by the Lombards and retaken by the Frankish kings Pippin and Charlemagne. Such was the foundation of the papal state.

The higher places in the government were occupied by the clergy, who for matters of detail made use of the civil and military officials who had carried on the administration under the Byzantine rule. But these lay officials could not long be content with a subordinate position, and hence arose incessant friction, which called for constant intervention on the part of the Frankish sovereigns. In 824 a kind of protectorate was organized and serious guarantees were conceded to the lay aristocracy.

Shortly afterwards, in the partition of the Carolingian Empire, Italy passed under the rule of a prince of its own, Louis II., who, with the title of emperor, made his authority felt in political matters. Shortly after his death (875) fresh upheavals reduced to nothing the power of the Carolingian princes; the clergy of Rome found itself without a protector, exposed to the amity of the lay aristocracy. The authority of the pontificate was seriously impaired by these circumstances. One of the great families of Rome, that of the vestararius Theophylact, took possession of the temporal authority, and succeeded in influencing the papal elections. After Theophylact the power passed to his daughter Marozia, a woman of the most debased character; then to her son Alberic, a serious-minded prince; and then to Alberic's son Octavius, who from "prince of the Romans" became pope (John XII.) when yet a mere boy. After Marozia, Alberic, and Octavius, who, under the name of Marozia and the Crescentii, exercised the temporal powers of the Holy See; and after them the same régime was continued by the counts of Tusculum, who were sprung from the same stock, which sometimes provided the Roman Church with the most unlikely and least honourable pontiffs.

The pope, like all the bishops, was chosen by means of election, in which both the clergy and the laity took part. The latter were represented in the most essential functions of the election by the aristocracy: at first by the senate, and later by the exercicius romanus, or rather of its staff, composed of Byzantine officers. It was the latter which gave rise to the feudal aristocracy which we see appearing among the Carolingians. The new pope was chosen by the principal members of the clergy and nobles, and then set before the assembled people, who gave their decision by acclamation; and this acclamation was accepted as the vote of the assembly of the faithful. The pope-elect was then put in possession of the episcopal house, and after waiting till the next Sunday his consecration was proceeded with. This ceremony was first celebrated in the Lateran, but from Byzantine times onwards it took place at St Peter's. It was also under the Byzantine régime that the formula was imposed that the pope should not be consecrated until the emperor had made his election.

This had not been required under the old Latin emperors or under the Gothic kings, and it disappeared of its own accord with the Byzantine régime. It was revived, however, by the emperor Louis the Pious, much to the disgust of the Romans, who resisted on several occasions. The Roman "princes" or "senators" in the 9th century went still further: it was they who actually nominated the pope. The same was the case with the Saxon emperors (Otto I., II., and III.), and in the 11th century of the lords of Tusculum, the latter nominating themselves and choosing members of their own family for the pontificate. When the emperor Henry III. (1046) put an end to this oppression it was only to substitute another. The popes of Tusculum did, at least, belong to the country, while the German kings chose bishops from the other side of the Alps.

Such was the state of affairs up to the time of Hildebrand.

The career of Hildebrand is a brilliant example of a great man. The fifteenth of January 1073, by the advent of the new pontiff, who had just come out of the sanctuary of St Peter's to take up his residence in the Lateran, was a day of acclamation. The whole city followed him with the applause of the crowd. It was the anniversary of a day of victory over the Moslems taken by Charles the Bald, the emperor of the Franks, and by Henry I. of Germany, beginning the era of new imperial power.

1 On the 5th of April 1046, six days after the death of Pope Stephen X., John, bishop of Velletri, the nominee of the Roman nobles, was enthroned as Pope Benedict X. Hildebrand set up a rival, bishop of Florence, in the person of the Count of Tuscany, who was the successor of the Romans to his cause, and secured the support of the empress Agnes at the Diet of Augsburg in June. Gerard was elected pope at Siena (as Nicholas II., q.v.) by those cardinals who had fled from Rome on the elevation of Benedict X. A synod was held at Sutri, at which the powerful Godfrey, duke of Lorraine and Spoleto, and margrave of Tuscany, and the chancellor Wilbert were present. Measures were here concerted against Pope Benedict, who was driven out of Rome in January 1059, Nicholas II. being
Side by side with the general movement towards reform, he had set before himself the object of freeing the papacy, not only from its temporal oppressors but also from its protectors. He was successful; however, the council of 1059, the pontifical election was placed out of reach of the schemes of the local feudal lords and restored to the heads of the clergy; certain reservations were made with regard to those rights which the Holy See was considered to have conceded personally to Henry of Germany (the young king Henry IV., son of the emperor Henry III.), but nothing more. At the election of Alexander II. (1061-1073)—a rival to whom was for a long time supported by the German king—and even at the election of Hildebrand, this rule had its effect. Henceforth the elections remained entirely free from those secular influences which had hitherto been so oppressive. In 1073 Hildebrand was raised to the pontifical throne by the acclamation of the people of Rome, under the name of Gregory VII.

The work of reform was now in a good way; the freedom of the pontifical elections had been assured, which gave some promise that the struggle against abuses would be conducted successfully. All that now remained was to find firmly the way that had already been opened. But this attitude was not likely to appeal to the exuberant energy of the new pope. Hitherto he had had to reckon with obstacles more powerful than those which were now left for him to conquer, and, what was more, with the fact that his authority depended upon the will of others. But now that his hands were no longer tied, he could act freely. The choice of the pope had been almost entirely removed from the sphere of secular influence, and especially from that of the German king. Gregory claimed that the same condition should apply to bishops, and these were the grounds of the dispute about investitures—a dispute which could find no solution, for it was impossible for the Teutonic sovereigns to renounce all interest in a matter of such importance in the workings of their state. Since the time of Clovis the German sovereigns had never ceased to intervene in such matters. But this question soon fell into the background. Gregory's contention was that the secular sovereigns should be entirely in the power of the head of the Church, and that he should be able to advance them or dispossess them at will, according to the estimate which he formed of their conduct. A terrible struggle arose between these obviously exorbitant demands and the resistance which they provoked. Its details cannot be described in this place (see Investitures); we need only say that this ill-fated quarrel was not calculated to advance the reform movement, but rather to impede it, and, further, that it ended in failure. Gregory died far away from Rome, upon which he had brought incalculable evils; and not only Rome, but the papacy itself had to pay the penalty for the want of moderation of the pope. Great indeed was the difference between the state in which he received it and that in which he left it. We must not, however, let this mislead us. This struggle between spiritual and secular powers, owing to the tremendous sensation which it created throughout Christendom, showed the nations that at the head of the Church there was a great force for justice, always able to combat iniquity and oppression, and sometimes to conquer them; how powerful the evil and the tyrants might seem. The scene at Canossa, which had at the moment a merely relative importance, remained in the memories of men as a symbol which was hateful or comforting, according to the point of view from which it was considered. As to Gregory's political pretensions, zealous theorists were quick to transform them into legal principles; and though his immediate successors, somewhat daunted by the disturbance which they had aroused, seemed to have neglected them at first, they were handed on to more distant heirs and reappeared in future struggles.

Gregory himself, in his last moments, seems to have felt that it was impossible to maintain them, for Didier, abbot of Monte-Cassino (Victor III., 1086-1087), whom he nominated as his successor, was well known for his moderation. It was no longer a question of continuing the policy of Gregory VII., but of saving the work of Hildebrand.

II.—Period from 1087 to 1305.

Gregory VII. had clearly revealed to the world the broad lines of the religious and political programme of the medieval papacy, and had begun to put it into execution.

To reform the Church in every grade and purify the priesthood in order to shield it from feudal influences and from the domination of lay sovereigns; to convert the Church thus regenerated, spiritualized, and detached from the world, into an organism which would be submissive to the absolute authority of the papal see, and to concentrate, at Rome all its energies and jurisdictions; to establish the supremacy of the Roman see over all the Christian Churches, and win over to the Roman Church the Churches of the Byzantine Empire, Africa and Asia; to establish the temporal domain of St Peter, not only by taking possession of Rome and Italy, but also by placing all the thrones of Europe under the supreme sovereignty of the popes, or even in direct vassalage to them; and, finally, to maintain unity of faith in Christendom and defend it against the attacks of unbelievers, Mussulmans, heretics and pagans—these were the main features of his scheme. The task, however, was so gigantic that after 150 years of strenuous effort, at the period which may be considered as the apogee of its power, that is, in the first half of the 13th century, the papacy had attained only incomplete results. At several points the work remained unfinished, for decadence followed close upon the moment of extreme greatness. It is more particularly in the part of this programme that relates to the internal policy of the papacy, to the subjection of the Church to the Curia, and to the intensive concentration of the ecclesiastical forces in the hands of the leader of Christendom, that Gregory went farthest in the execution of his plan and approached nearest the goal. For the rest, so formidable were the external obstacles that, without theoretically renouncing his claims, he was unable to realize them in practice in a manner satisfactory to himself.

In order to give a clear idea of the vicissitudes through which the papal institution passed between the years 1087 and 1305 and to show the measure of its success or failure at different stages in its course, it is convenient to divide this section into four periods.

I.—Period from Urban II. to Calixtus II. (1087–1124).—Gregory VII.'s immediate successors accomplished the most pressing work by liberating the Church from feudal subjection, either by force or by diplomacy. This was, indeed, the indispensable condition of its internal and external progress. The great figure of this period is unquestionably the French Cluniac Urban II., who led the Hildebrandine reformation with more vehemence than Gregory himself and was the originator of the crusades. Never throughout the middle ages was pope more energetic, impetuous or uncompromising. His inflexibilism will informed the movement directed against the enemy within, against the simoniacal prelate and the princely usurper of the rights of the Church, and prescribed the movement against the enemy without, against the infidel who held the Holy Sepulchre. Urban set his hand to reforms from which his predecessor Gregory had recoiled. He simultaneously excommunicated several sovereigns and particularly Louis VI. of France, who had been consecrated in 1080 and hostile to reform. He took no pains to temper the zeal of his legates, but incited them to the struggle, and, not content with prohibiting lay investiture and simony, expressly forbade prelates and even priests to pay homage to the civil power. Disturbing the secular clergy, who were wholly sunk in the world, he looked to the regular clergy for support, and thus led the papacy into that course which it continued to pursue after his death. Henceforth the monk was to be the dole instrument of the wishes of Rome, to be...
PAPACY

opposed to the official priesthood according to Rome's needs. Urban was the first to proclaim with emphasis the necessity of a close association of the Curia with the religious orders, and this he made the essential basis of the theocratic government. As the originator of the first crusade, Urban is entitled to the honour of the idea and its execution. There is no doubt that he wished to satisfy the complaints that emanated from the Christians dwelling in Jerusalem and from the pilgrims to the Holy Sepulchre, but it is no less certain that he was disturbed by the fears aroused throughout the Latin world by the recrudescence of Mussulman invasions, and particularly by the victory won by the Almoravides over the Christian army at Zalaca (1086). The progress of these African Mussulmans into Spain and their incessant piracies in Italy were perhaps the occasional cause that determined Urban II. to work upon the imagination of the infidels by an expedition into Syria. The papacy of that time believed in the political unity of Islam, in a solidarity—which did not exist—among the Mussulmans of Asia Minor, Syria, Egypt and the Barbary coast; and if it waited until the year 1095 to carry out this project, it was because the conflict with the Germanic Empire prevented the earlier realization of its dream. The essential reason of Urban II.'s action, and consequently the true cause of the crusade, was the ambition of the pope to unite with Rome and the Roman Church the Churches of Jerusalem, Antioch, Alexandria and even Constantinople, which the Greek schism had rendered independent. This thought had already crossed the minds of Leo IX. and Gregory VII., but circumstances had never allowed them to put it into execution. Armed by the reformation with a moral authority which made it possible to concentrate the forces of the West under the supreme direction of the Church and its leaders, Urban II. addressed himself with his customary decision to the execution of this enormous enterprise. With him, as with all his successors, the idea of a collective expedition of Europe for the recovery of the Holy Places was always associated with the sanguine hope of extinguishing the schism at Constantinople, its very centre, by the substitution of a Latin for a Byzantine domination. Of these two objects, he was only to realize the former; but the crusade may well be said to have been his own work. He created it and preached it; he organized it, dominated it, and constantly supervised it. He was ever ready to act, either personally or through his delegates, and never ceased to be the effective leader of all the feudal soldiers he enrolled under the banner of the Holy See. He corresponded regularly with his legates and with the military leaders, who kept him accurately informed of the position of the troops and the progress of the operations. He acted as intermediary between the soldiers of Christ and their brothers who remained in Europe, announcing successes, organizing fresh expeditions, and spurring the laggards to take the road to Jerusalem.

The First Crusade.

The vast conflict aroused by the Hildebrandine reformation, and particularly the investiture quarrel, continued under the three successors of Urban II.; but with them it assumed a different character, and a tendency was displayed to mitigate it. The violence and disorders provoked by the struggle brought about a reaction, which was organized by certain prelates who advocated a policy of conciliation, such as the Frenchman Ivo, bishop of Chartres (c. 1040-1116). These conciliatory prelates were sincere supporters of the reformation, and combated simony, the marriage or concubinage of priests, and the immorality of sovereigns with the same conviction as the most ardent followers of Gregory VII. and Urban II.; but they held that the intimate union of Church and State was indispensable to the social order, and that the rights of kings should be respected as well as the rights of priests. The text they preached was harmony between the priesthood and the state. Dividing what the irreconcilables of the Hildebrandine party considered as an indissoluble whole, they made a sharp distinction between the property of the Church and the Church itself, between the political and territorial power of the bishops and their religious authority, and between the feudal investiture which confers lands and jurisdiction and the spiritual investiture which confers ecclesiastical rights. This doctrine gradually riled all moderate minds, and finally inspired the directors of Christendom in Rome itself. It explains the new attitude of Paschal II. and Calixtus II., who were both sincere reformers, but who sought in a policy of compromise the solution of the difficult problem of the relations of Church and State.

History has not done sufficient justice to the Italian monk Paschal II., who was the equal of Urban in private virtues, personal disinterestedness, and religious conviction, but was surpassed by him in ardour and rigidity of conduct. Altered circumstances and tendencies of opinion called for a policy of conciliation. In France, Paschal granted absolution to Philip I.—who had many times been anathematized by his predecessors—and reconciled him solemnly with the Church, on the sole condition that he should swear to renounce his adulterous marriage. The pope could be under no delusion as to the value of this oath, which indeed was not kept; he merely regularized formally a state of affairs which the intractable Urban II. himself had never been able to prevent. As for the French question of the investitures, it was settled apparently without any treaty being expressly drawn up between the parties. The kings of France contemporary with Paschal II. ceased to practice spiritual investiture, or even to receive feudal homage from the bishops. They did not, however, renounce all intervention or all profit in the nominations to prelacies, but their intervention was no longer exhibited under the forms which the Hildebrandine party held to be illegal. In England, Paschal II. put an end to the long quarrel between the royal government and Anselm of Canterbury by accepting the Concordat of London (1107). The crown in England also abandoned investiture by the pastoral staff and ring, but, more fortunate than in France, retained the right of receiving feudal homage from the episcopate. As for Germany, the Emperor Henry V. wrung from the pope, by a display of force at Rome, concessions which provoked the indignant clamor of the most ardent reformers in France and Italy. It must not, however, be forgotten that, in the negotiations at Sutri, Paschal had pride and independence enough to propose to the emperor the only solution of the conflict that was entirely logical and essentially Christian, namely, the renunciation by the Church of its temporal power and the renunciation by the lay lords of all intervention in elections and investitures—in other words, the absolute separation of the priesthood and the state. The idea was contrary to the whole evolution of medieval Catholicism, and the German bishops were the first to repudiate it. At all events, it is certain that Paschal II. prepared the way for the Concordat of Worms. On the other hand, with more acuteness than his predecessors, he realized that the papacy could not sustain the struggle against Germany unless it could rely upon the support of another Christian kingdom of the West; and he concluded with Philip I. of France and Louis the Fat, at the Council of Troyes (1107), an alliance which was more than a century the foundation of the Savoyard dynasty. It was at this time that we find the popes in moments of crisis transporting themselves to Capetian territory, installing their governments and convening their councils there, and from that place of refuge fumilating with impunity against the internal and external foe. Without sacrificing the essential principles of the reformation, Paschal II. practised a policy of peace and reaction in every way contrary to that of the two preceding popes, and it was through him that the struggle was once more placed upon the religious basis. He refused to return Hugo, bishop of Die (d. 1106), as legate; like Urban and Gregory, he gave or confirmed monastic privileges without the protection he granted to the monks assuming a character of hostility towards the episcopate; and, finally, he gave an impulse to the reformation of the chapters, and, unlike Urban II., maintained the rights of the canons against the claims of the abbots.

Guy, the archbishop of Vienne, who had been one of the
keenest to disavow the policy of Paschal II., was obliged to continue it when he assumed the tiara under the name of Calixtus II. By the Concordat of Worms, which he signed with the Emperor Henry V. in 1122, the investiture was divided between the ecclesiastical and the lay powers, the emperor investing with the sceptre, the pope with the pastoral staff and ring. The work did honour to the perseverance and ability of Calixtus, but it was merely the application of the ideas of Paschal II. and Ivo of Chartres. The understanding, however, between the two contracting parties was very far from being clear and complete, as each party still sought to attain its own aim by spreading in the Christian world divergent interpretations of the concordat and widely-differing plans for reducing it to its final form. And, again, if this transaction settled the investiture question, it did not solve the problem of the reconciliation of the universal power of the popes with the claims of the emperors to the government of Europe; and the conflict subsisted—slumbering, it is true, but ever ready to awake under other forms. Nevertheless, the two great Christian agitations directed by the papacy at the end of the 11th century and the beginning of the 12th—the reformation and the crusade—were of capital importance for the foundation of the immense religious monarchy that had its centre in Rome; and it is from this period that the papal monarchy actually dates.

The entry of the Christians into Jerusalem produced an extraordinary effect upon the faithful of the West. In it they saw the most manifest sign of the divine protection and of the supernatural power of the pope, the supreme director of the expedition. At its inception the Latin kingdom of the Holy Land was within a little of becoming an ecclesiastical principality, ruled by a patriarch under the authority of the pope. Daimbert, the first patriarch of Jerusalem, was convinced that the Roman Church alone could be sovereign of the new state, and attempted to compel Godfrey of Bouillon to hand over to him by a solemn agreement the town and citadel of Jerusalem, and also Jaffa. The clergy, indeed, received a large share; but the government of the Latin principality remained lay and military, the only form of government possible for a colony surrounded by perils and camped in a hostile country. Not only was the result of the crusade extremely favourable to the extension of the Roman power, but throughout the middle ages the papacy never ceased to derive almost incalculable political and financial advantages from the agitation produced by the preachers and the crusading expeditions. The mere fact of the crusaders being placed under the special protection of the Church and the pope, and loaded with privileges, freed them from the jurisdiction, and even, up to a certain point, from the lordship of their natural masters, to become the almost direct subjects of the papacy; and the common law was then practically suspended for the benefit of the Church and the leader who represented it.

As for the reformation, which under Urban II. and his immediate successors was aimed not only at the episcopate but at the capitulary bodies and monastic clergy, it, too, could be seen by the remarkable extension of the authority of the successors of St Peter, for it struck an irreconcilable blow at the ancient Christian hierarchy. The first manifest result of the change was the weakening of the metropolitan. The visible symptom of this decay of the archiepiscopal power was the growing frequency during the Hildebrandine conflict of episcopal confirmations and consecrations made by the popes themselves or their legates. From an active instrument of the religious society, the archiepiscopate degenerated into a purely formal power; while the episcopate itself, which the sincere reformers wished to liberate and purify in order to strengthen it, emerged from the crisis sensibly weakened as well as ameliorated. The episcopate, while it gained in intelligence and morality, lost a part of its independence. It was raised above feudalism only to be abused before the two directing forces of the reformation, the papacy and the religious orders.

To place itself in a better posture for combating the simoniacal and concubinage prelates, the court of Rome had had to multiply exemptions and accelerate the movement which impelled the monks to make themselves independent of the bishops. Even in the cities, the seats of the episcopal power, the reformation encouraged the attempts at revolt or autonomy which tended everywhere to diminish that power. The cathedral chapters took advantage of this situation to oppose their jurisdiction to that of the bishops, and to encroach on their prerogatives. When war was declared on the schismatic prelates, the reforming popes supported the canons, and, unconsciously or not, helped them to form themselves into privileged bodies living their own lives and affecting to recognize the court of Rome as their only superior authority. Other adversaries of the episcopate, the burgesses and the petty nobles dwelling in the city, also profited by these frequent changes of bishops, and the disorders that ensued. It was the monarchy of the bishops of Rome that naturally benefited by these attacks on the aristocratic principle represented by the high prelacies in the Church. By drawing to their side all the forces of the ecclesiastical body to combat feuds, Urban II. and his successors, with their monks and legates, changed the constitution of the Church and imparted it to their own advantage. The new situation of these popes and the growth of their authority were also manifested in the material organization of their administration and chancery. Under Urban II. the formulary of the papal bulls began to crystallize, and the letters ammassed in the papal offices were differentiated clearly into great and little bulls, according to their style, arrangement and signs of validation. Under Paschal II. the type of the leaden seal affixed to the bulls (representing the heads of the apostles Peter and Paul) was fixed, and the use of Roman minuscule finally substituted for that of the Lombard script.

2. Period from Honorius II. to Celestine III. (1124-1198).— After the reformation and the crusade the papal monarch existed, and the next step was to consolidate and extend it. This task fell to the popes of the 12th century. Two of them in particular—the two who had the longest reigns—viz. Innocent II. and Alexander III., achieved the widest extension of the power entrusted to them, and in many respects their pontificates may be regarded as a preparation for and adumbration of the pontificate of Innocent III. This period, however, is characterized not only by the thoroughgoing development of the authority of the Holy See, but also by the severe struggle the popes had to sustain against the hostile forces that were opposed to their conquests or to the mere exercise of what they regarded as their right.

In the secular contest, Germany and the imperialist pretensions of its leaders were invariably the principal obstacle. Until the accession of Adrian IV., how-
Anacletus and the kingdom of the Two Sicilies, involved him in a course which was not precisely favourable to the imperial rights. Innocent II. was the virtual master of this monarch, whose championship of the papacy brought not the smallest advantage, not even that of being crowned emperor with the habitual ceremonial at the place consecrated by tradition. It may even be maintained that his elevation was due solely to his personal claims. This was a victory for Rome, and it was repeated in the case of the first Hohenstaufen, Conrad III., who owed his elevation (1138) mainly to the princes of the Church and the legate of Innocent II., by whom he was crowned. He also had to submit to the consequences of his origin on the occasion of a double election not foreseen by the Concordat of Worms, when he was forced to admit the necessity of appeal to Rome and to acknowledge the supremacy of the papal decision. The situation changed in 1152, under Eugenius III., when Frederick Barbarossa was elected German king. He made his election to the pope, but did not seek the pope’s approval. None the less, Eugenius III. facilitated the new sovereign on his election, and even signed the treaty of Constance with him (1153). The pope had need of Frederick to defend him against the revolted Romans and to help him to recover his temporal power, which had been gravely compromised. Anastasius IV. pursued the same policy, and summoned the German to Rome (1154). Frederick, however, was determined to keep the seat of Empire for himself, to dispute Italy with the pope, and to oppose the divine right of kings to the divine right of priests. When he had taken Lombardy (1158) and had had the principles of the imperial supremacy proclaimed by his jurists at the diet of Roncaglia, the court of Rome realized that war was inevitable, and two energetic popes, Adrian IV. and Alexander III., resolutely sustained the struggle, the last for nearly twenty years. Victims of the communal claims at Rome, they constituted themselves the champions of similar claims in northern Italy, and their alliance with the Lombard communes ultimately led to success. In his duel with Barbarossa, Alexander III., one of the greatest of medieval popes, displayed extraordinary courage, address and perseverance. Although it must be admitted that the tenacity of the Lombard republics contributed powerfully to the pope’s victory, and that the triumph of the Milanese at Legnano (1179) was the determining cause of Frederick’s submission at Venice, yet we must not exaggerate the importance of the solemn act by which Barbarossa, kneeling before his conqueror, recognized the spiritual supremacy of the Holy See, and swore fidelity and respect to it. In its final form, the truce of Venice was not only unfavourable secularly to the Empire, but even granted it very extensive advantages. Nor must it be forgotten that, in the eyes of contemporaries, the scene at Venice had none of that humiliating character which later historians have attributed to it.

This was not the only success gained by Alexander III. over lay sovereigns. The conflict of the priesthood with the kingdoms and nations that were tending to aggrandize themselves by transcending the religious limits of the mediæval theocracy took place on another theatre. Alexander and Henry II. of England.

The affair of Thomas Becket (q.v.) involved the papacy in a quarrel with the powerful monarchy of the Angevins, whose representative, Henry II., was master of England and of the half of France. Alexander’s diplomatic skill and moral authority, reinforced by the Capetian alliance and the revulsion of feeling caused by the murder of Becket, enabled him to force the anathema against him, and even to do penance at the tomb of the martyr. The Plantagenet abjured the Constitutions of Clarendon, recognized the rights of the pope over the Church of England, and augmented the privileges and domains of the archbishopric of Canterbury. Although Becket was a man of narrow sympathies and by no means of liberal views, he had died for the liberties of his caste, and the aureole that surrounded him enhanced the prestige and ascendency of the papacy.

Unfortunately for the papacy, the successors of Alexander III. lacked vigour, and their pontificates were too brief to allow them to pursue a strong policy against the Germanic imperialism. Never were the leaders of the Church in such jeopardy as during the reign of Barbarossa’s son, Henry VI. This vigorous despot, whose ambitions were not all chimerical, had succeeded where his predecessors, including Frederick, had failed. His marriage with the heiress of the old Norman kings had made him master of Sicily and the duchy of Apulia and Calabria, and he succeeded in conquering and retaining almost all the remainder of the peninsula. Under Celestine III. the papal state was surrounded on every side by German soldiers, and but for the premature death of the emperor, whom Abbot Joachim of Florigus called the “hammer of the world,” the temporal power of the popes might perhaps have been annihilated.

The Norman kingdom, which had conquered Sicily and southern Italy at the end of the 11th century, was almost as grave a source of anxiety to the popes of this period. Not only was it very existence an obstacle to the spread of their temporal power in the peninsula, but it frequently acted in concert with the pope’s enemies and thwarted the papal policy. The attempts of Honorius II. (1128) and Innocent II. (1139) to wrest Apulia and Calabria from King Roger II., and Adrian IV.’s war with William I. (1156), were one and all unsuccessful; and the papacy had to content itself with the vassalage and tribute of the Normans, and allowed them to organize the ecclesiastical government of their domains in their own fashion, to limit the right of appeal to Rome, and to curtail the power of the Roman legates. At this period, moreover, the “Norman Question” was intimately connected with the “Eastern Question.” The Norman adventurers in Sicily and of Palermo and Naples perpetually tended to look for their aggrandizement to the Byzantine Empire. In the interests of their temporal dominion, the 12th-century popes could not suffer an Italian power to dominate on the other side of the Adriatic and instal itself at Constantinople. This contingency explains the vacillating and illogical character of the papal diplomacy with regard to the Byzantine problem, and, inter alia, the opposition of Eugenius III. in 1150 to Roger II.’s projected crusade, which was directed towards the conquest of the Greek state. The popes were under the constant sway of two contrary influences—on the one hand, the seducing prospect of subduing the Eastern Church and triumphing over the schism, and, on the other, the apprehension of seeing the Normans of Sicily, their competitors in Italy, increasing their already formidable power by successful expeditions into the Balkan Peninsula. Dread of the Normans, too, explains the singular attitude of the Curia towards the Commeni, of whom it was alternately the enemy and the protector or ally.

But, as regards its temporal aims on Italy, the most inconvenient and tenacious, if not the most dangerous, adversary of the 12th-century papacy was the Roman commune. Since the middle of the 12th century the party of municipal autonomy and, indeed, the whole of the European middle classes, who wished to shake off the feudal yoke and secure independence, had been ranged against the successor of St Peter. The first symptoms of resistance were exhibited under Innocent II. (1142), who was unable to stem the growing revolution or prevent the establishment of a Roman senate sitting in the Capitol. The strength of classical reminiscence and the instinct of liberty were reinforced by the support given to communal aspirations by the popular agitator and dangerous tribune, Arnold of Brescia (q.v.), whose theories arrived at an opportune moment to encourage the revoluted commons. He denied the power of clerks to possess feiefs, and allowed them only religious authority and titles. The successors of Innocent II. were even less successful in maintaining their supremacy in
Rome. Lucius III., when called upon to renounce all his regalian rights, fell mortally wounded in an attempt to drive the autonomists by force from the Capitol (1145). Under Eugenius III., the Romans sacked and destroyed the houses of the clerks and cardinals, besieged St Peter's and the Lateran, and massacred the pilgrims. The pope was forced to fly with the Sacred College, to escape the necessity of recognizing the commune, and thus left the field free to Arnold of Brescia (1145). On his return to Rome, Eugenius had to treat with his rebel subjects and to acknowledge the senate they had elected, but he was unable to procure the expulsion of the agitator. The more energetic Adrian IV. refused to truce to the municipality, placed it under an interdict (1155), and allied himself with Frederick Barbarossa to quell an insurrection which respected the rights of emperors no more than the rights of popes. From the moment that Arnold of Brescia, absorbed in his chimerical project of reviving the ancient Roman republic, disregarded the imperial power and neglected to shelter himself behind the German in his conflict with the priesthood, his failure was certain and his fate foredoomed. He was hanged and burned, probably in pursuance of the Curia and the emperor; and Adrian IV. was reconciled with the Romans (1159). The commune, however, subsisted, and was on several occasions strong enough to eject the masters who were distasteful to it. Unfortunately for Alexander III., the Roman question was complicated during his pontificate by the desperate struggle with the Empire. The populace of the Tiber welcomed and expelled him with equal enthusiasm, and when his body was brought back from exile, the mob went before the cortège and threw mud and stones upon the funeral litter. All obeyed the pontiff of Rome—save Rome itself. Lucius III., who was pope for four years (1181-1185), remained in Rome four months, while Urban III. and Gregory VIII. never entered the city. At length the two parties grew weary of this state of revolution, and a régime of conciliation, the fruit of mutual concessions, was established under Clement III. By the act of 1188, the fundamental charter of the Roman commune, the people recognized the supremacy of the pope over the senate and the town, while the pope on his part sanctioned the legal existence of the commune and of its government and assemblies. Inasmuch as Clement was compelled to make terms with this new power which had established itself against him in the very centre of his dominion, the victory may fairly be said to have rested with the commune.

Although, among other obstacles, the popes of the 12th century had experienced some difficulty in subduing the inhabitants of the city, which was the seat and centre of the Christian world, their monarchy did not cease to gain in authority, solidity and prestige, and the work of centralization, which was gradually making them masters of the whole ecclesiastical organism, was accomplished steadily and without serious interruption. If Rome expelled them, they always found a sure refuge in France, where Alexander III. carried on his government for several years; and the whole of Europe acknowledged their immense power. Under Honorius II. the custom prevailed of substituting legates a latere, simple priests or deacons of the Curia, for the regency delegates, who had grown too independent; and that excellent instrument of rule, the Roman legate, carried the papal prestige to the remotest courts of Europe. The episcopate and the great monastic prelacies continued to lose their independence, as was shown by Honorius II. deputing a cardinal to Monte Cassino to elect an abbot of his choosing. The progress of the Roman power was especially manifested under Innocent II., who had triumphed over the schism, and was supported by the Empire and by Bernard of Clairvaux, the first moral authority of his time. He suspended an archbishop of Sens (1136) who had neglected to take into consideration the appeal to Rome, summoned an archbishop of Milan to Rome to receive the pallium from the pope's hands, lavished exemptions, and extended the right of appeal to such abnormal lengths that a Byzantine ambassador is reported to have exclaimed to Lothair III., "Your Pope Innocent is not a bishop, but an emperor." When the universal Church assembled at the second Lateran Council (1139), this leader of religion declared to the bishops that he was the absolute master of Christendom. "Ye know," he said, "that Rome is the capital of the world, that ye hold your dignities of the Roman pontiff as a vassal holds his fief of his sovereign, and that ye cannot retain them without his assent." Under Eugenius III., a Cistercian monk who was scarcely equal to his task, the papal absolutism grew sensibly weaker, and if we may credit the testimony of the usually well-informed German chronicler, Otto of Freising, there arose in the college of cardinals a kind of fermentation which was exceedingly disquieting for the personal power of the leader of the Church. In the case of a difference of opinion between Eugenius and the Sacred College, Otto relates that the cardinals addressed to the pope this astounding protest: "Thou must know that it is by us thou hast been raised to the supreme dignity. We are the hinges (cardines) upon which the universal Church rests and moves. It is through us that from a private person thou hast become the father of all Christians. It is, then, not right to enthrone thyself but rather to us that thou belongest henceforth. Thou must consult all thy recent friendships the traditional affections of the papacy. And thou must consult before every thing the general interest of Christendom, and must consider it an obligation of thine office to respect the opinions of the highest dignitaries of the court of Rome." If we admit that the cardinals of Eugenius III. succeeded in restricting the omnipotence of their master for their own ends, it must invariably have been the Curia that dictated its wishes to the Church and to Europe. The papacy, however, recovered its ascendency during the pontificate of Alexander III., and seemed more powerful than ever. The recently created royalties sought from the papacy the conservation of their titles and the benefit of their crowns, and placed themselves voluntarily in its vassalage. The practice of the nomination of bishops by the Curia and of papal recommendation to prebends and benefices of every kind grew daily more general, and the number of appeals to Rome and exemptions granted to abbeys and even to simple churches increased continually. The third Lateran Council (1179) was a triumph for the leader of the Church. At that council wise and commendable measures were taken against the abuses that discredited the priesthood, but the papal power of appeals and exemptions and the question of the increasing abuse of the power wielded by the Roman legates remained untouched. The treatise on canon law known as the Decretum Gratiani, which was compiled towards the middle of the 12th century and had an enduring and far-reaching effect (see Canon Law), merely gave theoretical sanction to the existing situation in the Church. It propagated doctrines in favour of the power of the Holy See, established the superiority of the popes over the councils, and gave legal force to their decreets. According to its author, "they (the popes) are above all the laws of the Church, and can use them according to their wish; they alone judge and cannot be judged."

It was by its constant reliance on monachism that the papacy of the 12th century had attained this result, and the popes of that period were especially fortunate in having for their champion the monk St Bernard, whose religious qualities enabled him to dominate public opinion. St Bernard completed the reformation, combatted heresy, and by his immense moral ascendancy gained victories by which Rome benefited. As instances of his more direct services, he put an end to the schism of 1139 and attached Italy and the world to the side of Innocent III. Although he had saved the papal institution from one of the gravest peril it had ever encountered, the cardinals, the court of Rome and Innocent himself could not easily pardon him for being what he had become—a private person more powerful in the Church than the pope and the bishops, and holding that power by his personal prestige. He incurred their special reproaches by his condemnation of the irresistible evolution which impelled Rome to desire exclusive dominion over Catholic Europe and to devote
her attention to earthly things. He did not condemn the temporal power of the popes in plain terms, but both his writings and his conduct proved that that power was in his opinion difficult to reconcile with the spiritual mission of the papacy, and was, moreover, a menace to the future of the institution. (See Bernard, Saint.)

At the very moment when the papacy thus attained omnipotence, symptoms of discontent and opposition arose. The bishops resisted centralization. Archbishop Hildebert of Tours protested to Honorius II. against the appeals to Rome, while others complained of the exactions of the legates, or, like John of Salisbury, animadverted upon the excessive powers of the bureaucracy at the Lateran. In the councils strange speeches were heard from the mouths of laymen, who were beginning to carry to extreme lengths the spirit of independence with regard to Rome. When a question arose at Toulouse in 1160 as to the best means of settling the papal schism, this audacious statement was made before the kings of France and England: "That the best course was to side with neither of the two popes; that the apostolic see had been ever a burden to the princes; that advantage must be taken of the schism to throw one or the other adrift, while awaiting the death of the other competitors, the authority of the bishops was sufficient in France and England alike for the government of the churches." The ecclesiastics themselves, however, were the first to denounce the abuses at Rome. The treatises of Gerhoh of Reichersberg (1093–1169) abound in trenchant attacks upon the greed and venality of the Curia, the arrogance and extortion of the legates, the abuse of exemptions and appeals, and the German policy of Adrian IV. and Alexander III. In his efforts to make the papal institution entirely worthy of its mission St Bernard himself did not shrink from presenting to the papacy "the mirror in which it could recognize its deformities." In common with all enlightened opinion, he complained bitterly of the excessive multiplication of exemptions, of the exaggerated extension of appeals to Rome, of the luxury of the Roman court, of the venality of the cardinals, and of the injury done to the traditional hierarchy by the very extent of the papal power, which was calculated to turn the strongest head. In St Bernard's treatise De consideratione, addressed to Pope Eugenius III., the papacy received with every reproach; any remonstrance was spoken of as a sign of affection and friendly counsel. To warn Eugenius again pride, Bernard reminds him in biblical terms that an insensate sovereign on a throne resembles "an ape upon a housetop," and that the dignity with which he is invested does not prevent him from being a man, that is, "a being, naked, poor, miserable, made for till and not for honours." To his thinking, poison and the dagger were less to be feared by the pope than the lust of power. Ambition and cupidity were the source of the most deplorable abuses in the Roman Church. The cardinals, said Bernard, were satraps who put pomp before the truth. He was at a loss to justify the unheard-of luxury of the Roman court. "I do not find," he said, "that St Peter ever appeared in public loaded with gold and jewels, clad in silk, mounted on a white mule, surrounded by soldiers and followed by a brilliant retinue. In the glitter that environs thee, rather wouldst thou be taken for the successor of Constantine than for the successor of Peter."

At Rome, however, had greater dangers to cope with than the ingrate reproofs of his friends the monks, and the opposition of the bishops who were discredited at the spectacle of their authority waning day by day. The resistance of this period that the Catholic edifice of the middle ages began to be shaken by the boldness of philosophical speculation as applied to theological studies and also by the growth of heresy. Hitherto more tolerant of heresy than the local authorities, the papacy now felt compelled to take defensive measures against it, and especially against Albigensesianism, which had made great strides in the south of France since the middle of the 12th century. Innocent II., Eugenius III. and Alexander III. excommunicated the sectaries of Languedoc and their abettors, Alexander even sending armed missions to hunt them down and punish them. But the preaching of the papal legates, even when supported by military demonstrations, had no effect; and the Albigensian question, together with other questions vital for the future of the papacy, remained unsettled and more formidable than ever when Innocent III. was elected.

3. Period from Innocent III. to Alexander IV. (1198–1261).—Under the pontificates of Innocent III. and his five immediate successors the Roman monarchy seemed to have reached the pinnacle of its moral prestige, religious authority and temporal power, and this development was due in great measure to Innocent III. himself. Between the perhaps excessive admiration of Innocent's biographer, Friedrich von Hurter, and the cooler estimate of a later historian, Félix Rocquain, who, after taking into consideration Innocent's political mistakes, lack of foresight and numerous disappointments and failures, concludes that his reputation has been much exaggerated, it is possible to steer a middle course and form a judgment that is at once impartial and conformable to the historical facts. Innocent was an eminent jurist and canonist, and never ceased to use his immense power in the service of the law. Indeed, a great part of his life was passed in hearing pleadings and pronouncing judgments, and few sovereigns have made a greater number of decisions, or shown such solicitude for the impartial exercise of their legal power. It is extremely difficult to comprehend Innocent's extraordinary activity. Over and above the weight of political affairs, he bore resolutely for eighteen years the overwhelming burden of the presidency of a tribunal before which the whole of Europe came to plead. To him, also, in his capacity of theologian, the whole of Europe submitted every obscure, delicate or controverted question, whether legal problem or case of conscience. This, undoubtedly, was the part of his task that Innocent preferred, and it was to this, as well as to his much overrated moral and theological treatises, that he owed his enormous contemporary prestige. As a statesman, he certainly committed grave faults—through excess of diplomatic subtlety, lack of forethought, and sometimes even through ingenuity; but it must with justice be admitted that, in spite of his reputation for pugnacity and obstinacy, he never failed, either by temperament or on principle, to exhaust every peaceful expedient in settling questions. He was averse from violence, and never resorted to bellicose acts or to the employment of force save in the last extremity. If his policy missed, it was in his desire to accomplish so much good for so many others; and if we consider the sum of his efforts to achieve the programme of the medieval papacy, it cannot be denied that the extent of his rule and the profound influence he exerted on his times entitle him to be regarded as the most perfect type of medieval pope and one of the most powerful figures in history.

A superficial glance at Innocent's correspondence is sufficient to convince us that he was pre-eminently concerned for the reformation and moral welfare of the Church, and that the Fourth Lateran Council, 1215, was animated by the best intentions for the re-establishment in the ecclesiastical body of order, peace and respect for the hierarchy. This was one of the principal objects of his activity, and this important side of his work received decisive sanction by the promulgation of the decrees of the fourth Lateran Council (1215). At this council almost all the questions at issue related to reform, and many give evidence of great breadth of mind, as well as of a very acute sense of contemporary necessities. Innocent's letters, however, not only reveal that superior wisdom which can take into account practical needs and relax strictures of principle at the right moment, but also that tolerance which is always opposed to the excess of zeal and intellectual narrowness of subordinates, but they also prove that, in the internal government of the Church, he was bent on gathering into his hands all the motive threads, and that he stretched the absolutist tradition to its furthest limits, intervening in the most trifling acts in the lives of the clergy, and regarding it as an obligation of his office to act and think for all. The heretic peril, which increased during his pontificate, forced him to take decisive measures against the Albigenses in the south of France, but
PAPACY

before proscribing them he spent ten years (1308-1308) in endeavouring to convert the misbelievers, and history should not forget the passionate character of these early efforts. It was because they did not succeed that necessity and German emperor, himself imperial at Rome, the difficulties of the enterprise surpassed the powers even of a leader of religion. He succeeded in imposing his will on the nobles and communes in the patrimony of St Peter, and, as guardian of Henry VI.'s son Frederick, was for some time able to conduct the government of the kingdom of the Two Sicilies, but in his claims on the rest of Italy the failure of the temporal power was manifest. He was unable, either by diplomacy or force of arms, to make Italian unity redound to the exclusive benefit of the Holy See. Nor was his failure due to lack of activity or energy, but rather to the insuperable obstacles in his path—the physical configuration of Italy, and, above all, the invincible repugnance of the Italian municipalities to submit to the mastery of a religious power.

As far as the Empire was concerned, chance at first favoured Innocent. For ten years a Germany weakened and divided by the rivalry of Philip of Swabia and Otto of Brunswick, Innocent III., left his hands free to act in Italy, and his pontificate marked a period of comparative quiet in the ardent conflict between pope and emperor which continued throughout the middle ages. Not until 1210, when Otto of Brunswick turned the imperial forces to which he owed his crown away from Innocent compelled open hostilities; and the struggle ended in a victory for the Curia. Frederick II., the new emperor created by Innocent, began by handing over his country to Rome and sacrificing the rights of the Empire to the union of the two great authorities of the Christian world. In his dealings with Frederick, Innocent experienced grievous vicissitudes and disappointments, but finally became master of the situation. One nation only—the France of Philip Augustus—was able to remain outside the Roman vassalage. There is not a word, in the documents concerning the relations of Philip Augustus with Rome, from which we may conclude that the Capetian crown submitted, or that the papacy wished to impose upon it the effective suzerainty of the Holy See. Innocent III., had been able to encroach on France at one point only, when the Albigenian crusade had enabled him to exercise over the southern chiefства conquered by Simon de Montfort a political and secular supremacy in the form of collections of moneys. Finally, Innocent III. was more fortunate than his predecessors, and, if he did not succeed in carrying out his projected crusade and in making the Holy Places, he at least benefited by the Franco- Venetian expedition of 1299. From Constantinople assembled at Venice, diverted the crusade by an act of formal disobedience, marched on Constantinople, seized the Greek Empire and founded a Latin Empire in its place; and Innocent had to accept the fait accompli. Though condemning it on principle, he turned it to the interests of the Roman Church as well as of the universal Church. With joy and pride he welcomed the Byzantine East into the circle of vassal peoples and kingdoms of Rome bound politically to the see of St Peter, and with the same emotions beheld the patriarchate of Constantinople at last recognize Roman supremacy.

But from this enormous increase of territory and influence arose a whole series of new and difficult problems. The court of Rome had to substitute for the old Greek hierarchy a hierarchy of Latin bishops; to force the remaining Greek clergy to practise the beliefs and rites of the Roman religion and bow to the supremacy of the pope; to maintain in the Greco-Latin Eastern Church the necessary order, morality and subordination; to defend it against the greed and violence of the nobles and barons who had founded the Latin Empire; and to conduct the leaders of the new empire to submit to the apostolic power and execute its commands. In his endeavours to carry out the whole of this programme, Innocent III. met with insuperable obstacles and many disappointments. On the one hand, the Greeks were unwilling to abandon their religion and national cult, and scarcely recognized the ecclesiastical supremacy of the papacy. On the other hand, the upstart Latin emperors, far from proving...
submitive and humble tools, assumed with the puple the habits and pretensions of the sovereigns they had disposessed. Nevertheless, Innocent left his successors a much vaster and more stable political dominion than that of which he had received from his predecessors, since it comprised both East and West; and his five immediate successors were able to preserve this ascendancy. They even extended the limits of Roman imperialism by converting the pagans of the Baltic to Christianity, and further reinforced the work of ecclesiastical centralization by enlisting in their service a force which had recently come into existence and was rapidly becoming popular—the mendicant orders, and notably the Dominicans and Franciscans. The Roman power was also increased by the formation of the universities—privileged corporations of masters and students, which escaped the local power of the bishop and his chancellor only to place themselves under the direction and supervision of the Holy See. Mistress of the entire Christian organism, Rome thus gained control of international education, and the mendicant monks who formed her devoted militia lost no time in monopolizing the professorial chairs. Although the ecclesiastical monarchy continued to gain strength, the successors of Innocent III. were never able to command a majority of the cardinals. Under Gregory IX. (1227-1241), who succeeded the pontiffs of Innocent IV. (1243-1254) the conflict between the priesthood and the Empire was revived by the enigmatic Frederick II., the polygot and lettered emperor, the friend of Saracens, the despot who, in youth styled “king of priests,” in later years personified ideas that were directly opposed to the medieval theocracy; and the struggle lasted nearly thirty years. The Hohenstaufen succumbed to it, and the papacy itself received a terrible shock, which shook its vast empire to the foundations.

Nevertheless, the first half of the 13th century may be regarded as the grand epoch of medieval papal history. Supreme in the Calamitation Europe, the papacy gathered into a body of doctrine the decisions given in virtue of its enormous de facto power, and promulgated its decrees and oracula to form the immutable law of the Christian world. Innocent III., Honorius III., and Gregory IX. employed their jurisprudences to collect the most important of their rulings, and Gregory’s decrees became the definitive code of ecclesiastical law. By making laws for the Christendom of the present and the future, these popes employed themselves in giving a more regular form to their principal administrative organ, the Curia. The development of the Roman chancery is also a characteristic sign of the evolution that was taking place. From the time of Innocent III. the usages of the apostolic curricula became transformed into precise rules, which for the most part remained in force until the 15th century.

4. Period from Urban IV. to Benedict XI. (1261-1305)—This period comprised 13 pontificates, all of short duration (three or four years at the most, and some only a few months), with the exception of that of Boniface VIII., who was pope for nine years. This accidental fact constitutes a prime difference in favour of the preceding period, in which there were only five pontiffs during the first sixty years of the 13th century. Towards the end of the 13th century the directors of the Christian world occupied the throne of St Peter for too short a time to be able to make their personal views prevail or to execute their political projects at leisure after ripe meditation. Whatever the merit of Urban IV. or of Nicholas III., the brevity of their pontificates prevented any one of these ephemeral sovereigns from being a great pope. But other and far more important differences characterize this period. Although there was no theoretical restriction to the temporal supremacy and religious power of the papacy, certain historical facts of great importance contributed to the fatal diminution of their extent. The first of these was the preponderance of the French monarchy and nation in Europe. Founded by the conquests of Philip Augustus and Louis VIII. and legitimated and extended by the policy and moral influence of the crowned saint, Louis IX., the French monarchy enjoyed undisputed supremacy at the end of the 13th century and the beginning of the 14th; and this hegemony of France was manifested, not only by the extension of the direct power exercised by the French kings over all the neighbouring nationalities, but also by the establishment of Capetian dynasties in the kingdom of the Two Sicilies and in Hungary. From this time the sovereignty of Rome, like other sovereigns, had to submit to French influence. But, whereas the pope was sometimes compelled to become the instrument of the policy of the kings of France or the adventurers of their race, he was often able to utilize this new and pervading force for the realization of his own designs, although he endeavoured from time to time, but without enduring success, to shake off the overwhelming yoke of the French. In short, it was in the sphere of French interests much more than in that of the general interests of Latin Christendom that the activities of these popes were exerted. The fact of many of the popes being of French birth and France the field of their diplomacy shows that the supreme pontificate was already becoming French in character. This change was a prelude to the more or less complete subjection of the papacy to the French monarchs, a development which followed the 13th century at the period of the “Babylonian Captivity,” the violent reaction personified by Boniface VIII. affording but a brief respite in this irresistible evolution. It was the Frenchman Urban IV. (1261-1264) who called Charles of Anjou into Italy to combat the last heirs of Frederick II. and thus paved the way for the establishment of the Angevin dynasty on the throne of Naples. Under Clement IV. (1265-1268) an agreement was concluded by which Sicily was handed over to the brother of St Louis, and the victories of Bénévent (1266) and Tagliacozzo (1267) assured the triumph of the Guelph party and enabled the Angevins to plant themselves definitely on Neapolitan soil. Conradin’s tragic and inevitable end closed the last act of the secular struggle between the Holy See and the Empire. Haunted by the recollection of that formidable conflict and lulled in the security of the Great Interregnum, which was to render Germany long powerless, the papacy thought merely of the support that France could give, and paid no heed to the dangers threatened by the extension of Charles of Anjou’s monarchy in central and northern Italy. The Visconti of Gregory X. (1271-1276) made an attempt to bring about a compromise, and thus to combat the tendency which had influenced his two immediate predecessors. He placed himself outside the theatre of French influence, and occupied himself solely with the task of giving to the papal monarchy that character of universality and political superiority which had made the greatness of an Alexander III. or an Innocent III. He opposed the aggregating projects of the Angevins, intervened in Germany with a view to terminating the Great Interregnum, and sought a necessary counterpoise to Capetian predominance in an alliance with Rudolph of Habsburg, who had become an emperor without imperilling the papacy. The Orsini Nicholas III. pursued the same policy with regard to the independence and greatness of the Roman See, but died too soon for the cause he upheld, and, at his death in 1280, the inevitable current revived with overpowering force. His successor, Martin IV. (1281-1285), a prelate of Champagne, brother of several councillors of the king of France, prebendar at Rouen and Tours, and one of the most zealous supporters of the canonization of Louis IX. of France, the papal throne under the auspices of Charles of Anjou, and undertook the government of the Church with the sole intention of furthering in every way the interests of the country of his birth. A Frenchman before everything, he abused the papal power to such an extent as to excite the indignation of his contemporaries, often slavishly subordinating it to the exigencies of the domestic and foreign policy of the Angevins at Naples and the reigning house at Paris. But he was prevented from carrying out this policy by an unforeseen blow, the Sicilian Vespers (March 1282), an event important both in itself and in its results. By rejecting the Capetian sovereign that Rome wished to thrust upon it to deliver it from the dynasty of Aragon, the little island of Sicily arrested the progress of French imperialism, ruined the vast
projects of Charles of Anjou, and liberated the papacy in its own despite from a subjection that pervaded and shook its power. Honorius IV. (1265-1285) and Nicholas IV. (1285-1292) were able to act with greater dignity and independence than their predecessors. Though remaining leagued with the Angevins in southern Italy, they dared to look to Germany and Rudolph of Habsburg to help them in their efforts to add to the papal dominion a part of northern Italy and, in particular, Tuscany. But they still continued to desire the restoration of the Angevin dynasty in Sicily and to assist the designs of France on Aragon by preaching a crusade against the masters of Barcelona and Palermo. The hopes of the Curia were frustrated by the resistance of the Aragonese and Sicilians, and Charles of Valois, to whom the Curia eventually destined the crown of Aragon, had to resign it for that of Constantinople, which he also failed to secure.

Boniface VIII. himself at the beginning of his pontificate yielded to the current, and, like his predecessors, adapted his external policy to the pretensions and interests of the great Capetian house, which, like all his predecessors, he at first countenanced. In spite of his instincts for dominion and the ardour of his temperament, he made no attempt to shake off the French yoke, and did not decide on hostilities with France until Philip the Fair and his Legists attempted to change the character of the kingship, emphasized its lay tendencies, and exerted themselves to gratify the desire for political and financial independence which was shared by the French nation and many other European peoples. The war which ensued between the pope and the king of France ended in the complete defeat of the papacy, which was reduced to impotence (1303), and though the storm ceased during the nine months' pontificate of Benedict XI., the See of St Peter recovered neither its normal equilibrium nor its traditional character. The accession of the Angignon pope, Clement V., marks the final subjection of the papal power to the Capetian government, the inevitable result of the European situation created in the preceding century.

In other respects the papacy of this period found itself in a very inferior situation to that which it had occupied under Innocent III. and the popes of the first half of the 13th century. The fall of the Latin Empire and the retaking of Constantinople by the Palaeologi freed a great part of the Eastern world from the political and religious direction of Rome, and this fact necessarily engaged the diplomacy of Urban IV. and his successors in an entirely different direction. To them the Eastern problem presented a less complex aspect. There could no longer be any serious question of a collective expedition of Europe for the recovery of the Holy Places. The ingenuous faith of a Louis IX. was alone capable of giving rise to two crusades organized privately and without the influence or even the approval of the pope. Although all these popes, and Gregory X. especially, never ceased theoretically to urge the Christian world to the crusade, they were actuated by the desire of remaining faithful to tradition, and more particularly by the political and financial advantages accruing to the Holy See from the preaching and the crusading expeditions. The European state of mind no longer lent itself to such enterprises, and, moreover, under such brief pontificates, the attenuated Roman power could not expect to succeed where Innocent III. himself had failed. The main preoccupation of all these popes was how best to repair the injury done to orthodox Europe and to Rome by the destruction of the Latin Empire. Several of them thought of restoring the lost empire by force, and thus giving a pendant to the fourth crusade; but the Curia finally realized the enormous difficulties of such a project, and convinced themselves that the only practical solution of the difficulty was to come to an understanding with the Palaeologi and realize pacifically the long-dreamed union of the Greek and Latin Churches. The negotiations began by Urban IV. and continued more or less actively by his successors were at last concluded in 1274 by Gregory X. The Council of Lyons proclaimed the union, which was destined to be effective for a few years at least, and to be prolonged precariously in the midst of unfavourable circumstances. The Greek mind was opposed to the union; the acquiescence of the Byzantine emperors was but an ephemeral expedient of their foreign policy; and the peace between the Latins and Greeks settled on Byzantine soil could not endure for long. The principal obstacle, however, was the incompatibility of the popes’ Byzantine and Italian policies. The popes were in favour of Charles of Anjou and his dynasty, but Charles was hostile to the union of the two Churches, since it was his intention to seize the Byzantine Empire and substitute himself for the Palaeologi. Almost all the successors of Urban IV. were compelled to exert their diplomacy against the aggrandizing aims of the man they had themselves installed in southern Italy, and to protect the Greek emperor, with whom they were negotiating the religious question. On several occasions between the years 1277 and 1273 the Angevins of Naples, who had great influence in Achaea and Albania and were solidly supported by their allies in the Balkan Peninsula, nearly carried out their project; and in 1274 the opposition of Charles of Anjou came near to compromising the operations of the council of Lyons and ruining the work of Gregory X. The papacy, however, held its ground, and Nicholas III., the worthy continuator of Gregory, succeeded in preserving the union and triumphing over the Angevin power. The Angevins took their revenge under Martin IV., who was a staunch supporter of the French. Three weeks after his coronation Martin excommunicated the Greek emperor and all his subjects, and allied himself with Charles of Anjou and the Venetians to compass his downfall. In this case, too, the Sicilian Vespers was the rock on which the hopes and pretensions of the sovereign of Naples suffered shipwreck. After Martin’s death the last popes of the 13th century, and notably Boniface VIII., in vain thought to find in another Capetian, Charles of Anjou, the means of re-establishing the Latin dominion at Byzantium. But the East was lost; the union of 1274 was quickly dissolved; and the reconciliation of the two Churches again entered into the category of chimeras.

During this period the papal institution, considered in its internal development, already showed symptoms of decadence. The diminution of religious faith and sacerdotal prestige shook it to its very foundations. The growth of the lay spirit continued to manifest itself among the burghers of the towns as well as among the feudal princes and sovereigns. The social factors of communism and nationalism, against which Innocent III. and his successors had struggled, became more powerful and more hostile to theocratic domination. That a sovereign like St Louis should be able to associate himself officially with the feudalism of his realm to repress abuses of church jurisdiction; that a contemporary of Philip the Fair, the lawyer Pierre Dubois, should dare to suggest the secularization of ecclesiastical property and the conversion of the clergy into a class of functionaries paid out of the royal treasury; and that Philip the Fair, the adversary of Boniface VIII., should be able to rely in his conflict with the leader of the Church on the popular consent obtained at a meeting of the Three Estates of France—all point to a singular demoralization of the sentiments and principles on which were based the whole power of the pontiff of Rome and the entire organization of medieval Catholicism. Both by its attitude and by its governmental acts, the papacy of the latter 13th century itself contributed to increase the discredit and disaffection from which it suffered. Under Urban IV. and his successors the great moral and religious sovereignty of former times became a purely bureaucratic monarchy, in which the main preoccupation of the governors appeared to be the financial exploitation of Christendom. The relations of these popes, which are now being actively investigated and published, dispersions (licences to violate the laws of the Church); indulgences; imposts levied with increasing regularity on universal Christendom and, in particular, on the clerks; the
settlement of questions relating to church debts; the granting of lucrative benefices to Roman functionaries; the divers processes by which the Curia acquired the immediate disposal of monastic, capitular, and episcopal revenues— in short, all financial matters—were of the first importance. It was in the 14th century more especially that the Apostolic Chamber spread the net of its fiscal administration wider and wider over Christian Europe; but at the close of the 15th century all the preliminary measures had been taken to procure for the papal treasury its enormous and permanent resources. The continued efforts of the popes to drain Christian gold to Rome were limited only by the fiscal pretensions of the lay sovereigns, and it was this financial rivalry that gave rise to the inevitable conflict between Boniface VIII. and Philip the Fair.

By thus devoting itself to material interests, the papacy contemporary with the last Capetians lost its moral greatness and fell in the opinion of the peoples; and it did itself no less injury by the abnormal extension of the bounds of its absolutism. By its exaggerated methods of centralization the papal monarchy had absorbed within itself all the living forces of the religious world and suppressed all the liberties in which the Church of old had lived. The subjection of the secular clergy was complete, while the episcopate retained no shadow of its independence. The decree of Clement IV. (1266), empowering the papacy to dispose of all vacant bishoprics at the court of Rome, merely sanctioned a usage that had long been established. But the control exercised by the Roman Curia over the episcopate had been realized by many other means. It was seldom that an episcopal election took place without a division in the chapter, in which resided the electoral right. In such an event, the competitors appealed to the Holy See and abdicated their right, either voluntarily or under coercion, in manus papae, while the pope took possession of the vacant see. Nominations directly made by the court of Rome, especially in the case of dioceses for which, in the case of dioceses for which, became increasingly numerous. The principle of election by canons was repeatedly violated, and threatened to disappear; and at the end of the 13th century the spectacle was common of prelates, whether nominated or confirmed by the pope, entitling themselves “bishops by the grace of the Holy See.” The custom in force required bishops established by papal authority to take an oath of fidelity to the pope and the Roman Church, and this oath bound them in a particular fashion to the Curia. Those bishops, however, who had been elected under normal conditions, conformably to the old law, were deprived of the essential parts of their legitimate authority. They lost, for example, their jurisdiction, which they were seldom able to exercise in their own names, but in almost every case as commissaries delegated by the apostolic authority.

The regular clergy, who were almost wholly sheltered from the power of the diocesan bishops, found themselves, even more than the secular priesthood, in a state of complete dependence on the Curia. The papacy of this period continually intervened in the internal affairs of the monasteries. Not only did the monks continue to seek from the papacy the confirmation of their privileges and property, but they also referred almost all their disputes to the arbitration of the pope. Their elections gave rise to innumerable lawsuits, which all terminated at the court of Rome, and in most cases it was the pope himself who designated the monks to fill vacant posts in the abbeys. Thus the pope became the great ecclesiastical elector as well as the universal judge and supreme legislator. On this extreme concentration of the Christian power was employed throughout Europe an army of official agents or officious adherents of the Holy See, who were animated by an irrepressible ambition of personal advancement of the papacy. These officials originally consisted of an obedient and devoted militia of mendicant friars, both Francisans and Dominicans, who took their orders from Rome alone, and whose efforts the papacy stimulated by lavishing exemptions, privileges, and full senatorial powers. Subsequently they were represented by the apostolic notaries, who were charged to exercise throughout Christendom the gracious jurisdiction of the leaders of the Church and to preside over the most important acts in the private lives of the faithful. These tools of Rome, both clerks and laymen, continued to increase in every diocese. They were not invested with their office until they had been examined by a papal chaplain, or sometimes even by the vice-chancellor of the Curia.

The sovereign direction of this enormous monarchy belonged to the pope alone, who was assisted in important affairs by the advice and collaboration of the College of Cardinals, who had become the sole electors to the papacy. Towards the close of the 13th century the necessity arose for an express ruling on the question of the exercise of this electoral right. In 1274 Gregory X., completing the measures taken by Alexander III. in the 12th century, promulgated the celebrated constitution by which the cardinal-electors were shut up in conclaves and, in the event of their not having designated the new pope within three days, were constrained to perform their duty by a progressive reduction of their food-allowance (see CONCLAVE). But at the head of this vast body there existed a constant tendency which was opposed to the absorption of all the power by a single and unbridled will. In the last years of this period fresh signs appeared of a reaction that emanated from the Sacred College itself. The cardinal-electors endeavoured to derive from their electoral power a right of control over the acts of the pope elect. In 1294, and again in 1303, they laid themselves under an obligation, previously to the election, to subscribe to the political engagements which each promised rigorously to observe in the event of his becoming pope. In general, these engagements were based upon the limitation of the number of cardinals, the prohibition to nominate new ones without previous notification to the Sacred College, the sharing between the cardinals and the pope of certain revenues specified by a bull of Nicholas IV., and the obligatory consultation of the consistory for the principal acts of the temporal and spiritual government. It is conceivable that a pope of Boniface VIII.'s temperament would not submit kindly to any restriction of the discretionary power with which he was invested by tradition, and he endeavoured to make the cardinals dependent on him and even to dispense with their services as far as possible, only assembling them in consistory in cases of extreme necessity. This tendency of the Sacred College to convert the Roman Church into a constitutional monarchy, in which it should itself play the part of parliament, was a sufficiently grave symptom of the progress of the new spirit. But throughout the ecclesiastical society traditional bonds were loosened and anarchy was rife, and this at the very moment when the enemies of the priesthood and its leaders redoubled their attack. In fine, the decadence of the papal institution manifested itself in an irremediable manner when it had accomplished no more than the half of its task. The growth of national kingdoms, the anti-clerical tendencies of the emancipated middle classes, the competition of lay imperialisms, and all the other elements of resistance which had been encountered by the papacy in its progress and had at first tended only to shake it, now presented an insurmountable barrier. The papacy was weakened by its contest with these adverse elements, and it was through its failure to triumph over them that its dream of European dominion, both temporal and spiritual, entered but very incompletely into the field of realities.

(Al. Lu.)

III.—Period from 1305 to 1350.

The accession of the Gascon Clement V. in 1305 marks the beginning of a new era in the history of the papacy; for this pope, formerly archbishop of Bordeaux, remained in France, without once crossing the threshold of the Eternal City. Clement's motive for this reso- lution was his fear that the independence of the ecclesiastical government might be endangered among the frightful disensions and party conflicts by which Italy was then convulsed; while at the same time he yielded to the pressure
exercised on him by the French king Philip the Fair. In March 1306, Clement V. transferred his residence to Avignon, a town which at that time belonged to the king of Naples, but was surrounded by the county of Venetia, which as early as 1288 had passed into the possession of the Roman See. Clement V. remained at Avignon till the day of his death, so that with him begins the so-called Babylonian Exile of the popes. Through this, and his excessive subservience to Philip the Fair, his reign proved the reverse of salutary to the Church. The pope's subservience was above all conspicuous in his attitude towards the proceedings brought against the order of the Temple, which was dissolved by the council of Vienne (see Templars). His possession of Ferrara involved Clement in a violent struggle with the republic of Venice, in which he was ultimately victorious.

His successor John XXII. a native of Cahors, was elected as the result of very stormy negotiations, after a two years' vacancy of the see (1316). Like his predecessor John XXII., 1316-1334., he fixed his permanent residence at Avignon, where he had formerly been bishop. But while Clement V. had contented himself with the hospital of the Dominican monastery at Avignon, John XXII. installed himself with great state in the episcopal palace, hard by the cathedral. The essential features of this new epoch in the history of the papacy, beginning with the two popes mentioned, are intimately connected with this lasting separation from the traditional seat of the papacy, and from Italian soil in general: a separation which reduced the head of the Church to a fatal dependence on the French kings. Themselves Frenchmen, and surrounded by a College of Cardinals in which the French element predominated, the popes gave to their ecclesiastical administration a certain French character, till they stood in more and more danger of serving purely national interests, in cases where the obligations of their office demanded complete impartiality. And thus the prestige of the papacy was sensibly diminished by the view, to which the jealousy of the nations so soon gave currency, that the supreme dignity of the Church was simply a convenient tool for French statecraft. The accusation might not always be supported by facts, but it tended to shake popular confidence in the head of the universal Church, and to inspire other countries with the feeling of a national opposition to an ecclesiastical régime now entirely Gallicized. The consequent loosening of the ties between the individual provinces of the Church and the Apostolic See, combined with the capricious policy of the court at Avignon, which often regarded nothing but personal and family interests, accelerated the decay of the ecclesiastical organism, and justified the most dismal forbodings for the future. To crown all, the feud between Church and Empire broke out again with unprecedented violence. The most prominent leaders of the opposition to the papacy, whether ecclesiastical or political, joined forces with the German king, Louis of Bavaria, and offered him their aid against John XXII.

The clerical opposition was led by the very popular and influential Minorities who were at that time engaged in a remarkably bitter controversy with the pope as to the practical interpretation of the idea of evangelical poverty. Their influence can be clearly traced in the appeal to a general council, issued by Louis in 1324 at Sachsenhausen near Frankfort-on-the-Main. This document, which confused the political problem with the theological, was bound to envenom the quarrel between emperor and pope beyond all remedy. Side by side with the Minorites, the spokesmen of the specifically political opposition to the papacy were the Parisian professors, Marsilius of Padua and John of Jandun, the composers of the "Defender of the Peace" (defensor pacis). In conjunction with the Minorites and the Ghilleblines of Italy, Marsilius succeeded in enticing Louis to the fateful expedite to Rome and the revolutionary actions of 1328. The conferring of the imperial crown by the Roman populace, the deposition of the pope by the same body, and the election of an anti-pope in the person of the Minorite Pietro da Corvara, translated into acts the doctrines of the defensor pacis. The struggle, which still further aggravated the dependence of the pope on France, was waged on both sides with the utmost bitterness; and the end was not in sight when John XXII. died, full of years, on the 4th of December 1334.

Even the following pope, Benedict XII., a man of the strictest morality, failed, in spite of his mild and pacific disposition, to adjust the conflict with Louis of Bavaria and the eccentric Fraticelli. King Philip VI. and the cardinals of the French party worked energetically against the projected peace with Louis; and Benedict was not endowed with sufficient strength of will to carry through his designs in the teeth of their opposition. He failed, equally, to stifle the first beginnings of the war between France and England; but it is at least to his honour that he exerted his whole influence in the cause of peace.

His efforts in the direction of reform, moreover, deserve recognition. In Avignon he began to erect himself a suitable residence, which, with considerable additions by later popes, developed into the celebrated papal castle of Avignon. This enormous palace, founded on the cathedral rock, is an extraordinary mixture of palace and castle and fortress. It was Benedict XII. also who elevated the doctrine of the beatific vision of the saints into a dogma.

Benedict XII. was again succeeded, in 1342, by a Frenchman from the south, Pierre Roger de Beaufort, who was born in the castle of Maumont, in the diocese of Limoges. He assumed the title of Clement VI. In contrast with his peace-loving predecessor, and in accordance with his own more energetic character, he pursued with decision and success the traditions of John XXII. in his dealings with Louis of Bavaria. With great dexterity he turned the feud between the houses of Luxemburg and Wittelsbach to the destruction of Louis; and the death-struggle between the two seemed about to break out, when Louis met his untimely end. To all appearances the victory of the papacy was decisive; but it was a Pyrrhic victory, as events were quickly to prove. In Rome there ensued, during the pontificate of Clement, the revolutions of the visionary Cola di Rienzo (q.v.) who restored the old republic, though not for long. By his purchase of Avignon, and the creation of numerous French cardinals, the pope consolidated the close connexion of the Roman Church with France: but the interests of that Church suffered severely through the riches and patronage which Clement lavished on his relatives, and through the princely luxury of his court. His generosity—which degenerated into prodigality—compelled him to open fresh sources of revenue; and in this he succeeded, though not without serious detriment to the interests of the Church.

It was fortunate for the Church that Clement VI. was followed by a man of entirely different temperament—Innocent VI. This strict and upright pope appears to have taken Benedict XII.'s example. He undertook, though not with complete success, a reformation of ecclesiastical abuses; and it was he who assisted in restoring the empire at last to some measure of stability. But the culminating glory of his reign was the restoration of the almost ruined papal dominion in Italy, by means of the highly-gifted Cardinal Albornoz. The restoration of the Apostolic See to its original and proper seat was now possible; and the need for such a step was the more pressing, since residence in the castle at Avignon had become extremely precarious, owing to the ever-increasing confusion of French affairs. Innocent VI., in fact, entertained the thought of visiting Rome; but age and illness prevented his doing so.

The intention of Innocent was put into execution by his successor—the learned and pious Urban V. Two events of the first magnitude make his reign one of the most memorable in the century. The first of these was the return to Rome. This was an object which the emperor Charles IV. had prosecuted with all his energies; which alone could revive the languishing reputation of the papacy,
PAPACY

[Fondi, Sept. 20]. Robert assumed the style of Clement VII., and thus Christendom was brought face to face with the worst misfortune conceivable—the Great Schism (1378–1417).

The chief responsibility for this rests with the worldly College of Cardinals, who were longing to return to France, and thence drew their inspiration. This college was a creation of the Avignon period; which must therefore, in the last resort, be considered responsible for this appalling calamity. Severe censure, moreover, attaches to Charles V., of France. There may be room for dispute, as to the extent to which the king's share in the schism was due to the instigation of the revolted cardinals; there can be not the slightest doubt that his attitude was the decisive factor in perpetuating and widening the breach. The anti-pope was recognized not only by Charles of France, but by the princes of the Empire dependent on him, by Scotland and Savoy, and finally by the Spanish dominions and Portugal. On the other hand, the emperor Charles IV., and his son Wenceslaus, the greater part of the Empire, England, Hungary, Poland, Denmark, Norway and Sweden, together with the majority of the Italian states—Naples excepted—remained loyal to the pepe. Urban, in fact—who meanwhile had created a new College of Cardinals with members of different nationalities—enjoyed one great advantage; his rival failed to hold his own in Italy, with which country the actual decision, virtually, now fell. Unfortunately, in the time that followed, Urban was guilty of gross errors, pursuing his personal interests, and sacrificing, all too soon, that universal point of view which ought to have governed his policy. The struggle against his powerful neighbour on the frontier, Queen Joanna of Naples, rapidly became his one guiding motive; and thus he was led into a perfect labyrinth of blunders. He excommunicated the queen as a stiff-necked adherent of the French anti-pope, and in 1381 conferred the ambitious Charles of Durazzo, with whom he was soon inextricably embroiled; while, a little later, he fell out with his new College of Cardinals. On the 15th of October 1389, he died, with few to lament him.

After the death of Urban VI., fourteen cardinals of his obedience assembled, and after long negotiations selected the scion of a noble Neapolitan family, Cardinal Pietroboniface IX., Tomacelli (Nov. 2, 1389). The title which he took,1389-1404, was that of Boniface IX. The new pope—a man of high moral character, great sagacity, eloquence, and of a kindly disposition—at once instituted an entirely different policy from that pursued by his predecessor. This was especially the case in his treatment of the Lusso of Charles Durazzo, who had been assassinated in the February of 1386, received the royal crown at the hands of a papal legate. To his cause Boniface IX. closely attached himself; and his support of the king against the Angevins cost him enormous sums, without which Ladislaus could not have secured his victory over the French claimant. By these means, the schism was averted from Italy, and Naples won for the Roman obedience. The situation in the papal state, which Boniface found in the greatest confusion, was at the outset far more difficult to deal with. But here also he attained in time a considerable measure of success, although the methods employed were scarcely above criticism. His greatest success, however, was gained in the Eternal City itself; for he contrived, after many vicissitudes, to induce the Romans to annul their republican constitution and acknowledge the papal supremacy, even in municipal matters.

To give this supremacy a firmer basis, Boniface fortified the Vatican and the Capitol, and restored the castle of St. Angelo—which had previously been used as a quarry—providing it with walls and battlements, and erecting a tower in the centre. This castle, which was now a safe shelter to the pope. In January 1400, when the Colonnas made their attempt to surprise Rome. However, the adventure failed; and by the aid of Ladislaus, the castles of the Colonnas in the vicinity of Rome were destroyed. In 1401 this powerful family made its submission, accepting the favourable terms which the pope had had the good sense to

1See Pastor, Geschichte der Päpste, i., 121.
offer. Henceforward quiet prevailed, and Boniface ruled as a
stench master in Rome. But he was soon confronted with an
extremely dangerous enemy, in the person of Duke Gian
Galeazzo Visconti of Milan, who was aiming at the sovereignty
of all Italy. In July 1402 he made himself master of Bologna;
and his death in September of the same year was a stroke of
good fortune for the pope. Bologna was now recovered for
the Church (Sept. 2, 1403), and soon afterwards Perugia also
surrendered.

Thus Boniface IX., as a secular prince, occupies an important
position; but as pope his activity must be unfavourably judged.
Even if Dietrich of Niem frequently painted him too black,
there is no question that the means which Boniface employed
to fill the papal treasury seriously impaired the prestige of
the highest spiritual office and the reverence due to it.
His nepotism,
again, casts a dark shadow over his memory: but most regret-
able of all was his indifference towards the ending of the schism.
Yet it should be borne in mind, that, when Clement VII. died
suddenly on the 16th of September 1404, and the Avignon
cardinals immediately elected the Spaniard, Pedro de Luna, as
anti-pope (under the title of Benedict XIII.), Boniface IX. was
left face to face with an extraordinarily skilful, adroit, and
unscrupulous antagonist.

On the death of Boniface (Oct. 1, 1404), the Roman
cardinals once more elected a Neapolitan, Cosimo dei Migliorati, who, at
the age of 65, assumed the name of Innocent VII.
Innocent, who was animated by a great love for the
sciences and all the arts of peace, enjoyed only a brief
pontificate, but his reign is not without importance, if only
as an example of the generous patronage which the papacy—
even in its darkest days—has lavished on literature and science.
Significant also is the foothold gained at this time in the Curia
itself by the humanists—Poggio, Bruni and others. The
appointment of these skilled humanist writers to the Chancery
was a consequence of the difficult conditions of the time. The
crisis of the Catholic Church underwent, during this terrible
epoch, the greatest in all her history: for while everything
was thrown into the utmost confusion by the life and death
struggles of the rival popes, while the ecclesiastical revenues and
emoluments were used almost exclusively for the reward of
partisan service, while everywhere the worldliness of the clergy
had reached its highest pitch, heretical movements, by which
the whole order of the Church was threatened with overthrow,
were gaining strength in England, France, Italy, Germany and
especially in Bohemia.

The crisis came to a head in the pontificate of Gregory XII.

Gregory
XII., 1406-
1415.

This pope, so distinguished in many respects, owed his election
mainly to the circumstance that he was considered
a zealous champion of the restoration of unity within
the Church: and he displayed, in fact, during the
earlier portion of his reign, an exalted enthusiasm for this great
task. Later his attitude changed; and the protracted negotia-
tions for a conference with Benedict XIII. remained
unfruitful.
The result of this change in the attitude of Gregory was the
formation of a strong malcontent party in the College of
Cardinals; to counteract whose influence, the pope—faithless
to the conditions attached to his election—resorted to the
plan of creating new memers. Stormy discussions at Lucca
followed; but they failed to prevent Gregory from nominating
four fresh cardinals (May 9, 1408). The sequel was that
seven of the cardinals attached to Gregory's Roman Curia
withdrew to Pisa.

At the same period, the relations of Benedict XIII. with
France suffered a significant modification. In that country,
it became more and more manifest that Benedict
had no genuine desire to heal the schism in the
Church, in spite of the ardent zeal for union which
he had displayed immediately before and after his election.
In May 1410 France withdrew from his obedience; and it was
not long before French policy succeeded in effecting a
reconciliation
and understanding between the cardinals of Benedict XIII.
and those who had seceded from Gregory XII. Precisely as
if the Holy See were vacant, the cardinals began to act as the
actual rulers of the Church, and issued formal invitations to
a council to be opened at Pisa on the Feast
of the Annunciation (March 25) 1409. Both popes
attempted to foil the disaffected cardinals by
convening councils of their own; but their efforts were
doomed to failure.

On the other hand, the council of the cardinals—though,
by the strict rules of canonical law, its convocation was abso-
lutely illegal—attained the utmost importance. But these
rules, and, in fact, the whole Catholic doctrine of the primacy
were almost entirely obscured by the schism. Scholars like
Langenstein, Gerson and Zabarella, evolved a new theory as to
eccumenical councils, which from the point of view of Roman
Catholic principles must be described as revolutionary. At the
synod of the dissident cardinals, assembled at Pisa, views of
this type were in the ascendant; and, although protests were
not lacking, the necessities of the time served as a pretext for
ignoring all objections.

Thus the council was merely a tool in the hands of the
ambitious and adroit Baldassare Cossa, was a fact unsuspected
by its members who were animated by a fiery enthusiasm for
the re-establishment of ecclesiastical unity; nor did they pause
to reflect that an action against both popes could not possibly
be lawful. Since whole universities and numerous scholars
had pronounced in favour of the new theories, the Pisan synod
dismissed all canonical scruples, and unhesitatingly laid claim
to authority over both popes, one of whom was necessarily
the legitimate pope. It was in vain that Carlo di Malatesta, a
stanch adherent of Gregory, sought at the eleventh hour
to negotiate a compromise between Gregory and the synod. It
was in vain that this cultured prince, imbued with the principles
of humanism, represented to the cardinals that this new path
would lead quickly to the goal, but that this goal could not be
united but a triple schism. The council declared that it was
impossible to convene a universal, and representative of
the whole Catholic Church; and proceeded immediately to the
trial and deposition of Benedict XIII. and Gregory XII. The
synod grounded its procedure against the rival popes on a fact,
ostensibly patent to all, but actually believed by none—that
they were both supporters of the schism, and not merely this,
but heretics in the truest and fullest sense of the word, since
their attitude had impugned and subverted the article of faith
concerning the one Holy, Catholic and Apostolic Church.
On the ground of this extremely dubious declaration, designed
to compensate for the absence of any authentic and firm foundation
in ecclesiastical law, the Pisan assembly on the 5th of June
announced the deposition of Gregory XII. and Benedict XIII.,
as manifest heretics and partisans of the schism.

The next step was to elect a new pope; and on the 26th of June 1410 the choice fell on the venerable
cardinal-archbishop of Milan, the Greek Petros Filargiris, who
assumed the title of Alexander V.

The premature and futile character of these drastic
and violent proceedings at Pisa was only too speedily evident.
The powerful following which Gregory enjoyed in Italy and
Germany, and Benedict in Spain and Scotland, ought to have
shown from the very first that a simple decree of deposition
could never suffice to overthrow the two popes. Thus, as
the sentence of Pisa found recognition in France and England,
as well as in many parts of Germany and Italy, the synod,
which was to secure the restoration of unity, proved only the
cause for worse confusion—instead of two, there were now
three popes.

Alexander V., the pope of the council, died on the 3rd of May
1410. The cardinals at once elected his successor—Baldassare
Cossa, who took the name of John XXIII. Of all the
consequences of the disastrous Pisan council, the election of this man was the most unfortunate.
True, it cannot be demonstrated that all the fearful accusations
afterwards levelled at John XXIII. were based on fact: but
it is certain that this cunning politician was so far infected with
PAPACY

[1305-1590]

By consenting to this, the synod indirectly acknowledged that its previous sessions had not possessed an ecumenical character, and also that Gregory's predecessors, up to Urban VI., had been legitimate popes. In presence of Gregory

Council of

Constance. By consent of the other parties, Sigismund, who was inspired by the best motives, and who succeeded in surmounting the formidable obstacles which barred the way to an ecumenical council. It was mainly due to Sigismund's indefatigable and magnificent activity, that the council of Constance met and was so numerous and attended. It is remarkable how fortune seemed to assist his efforts. The capture of Rome by King Ladislaus of Naples had compelled John XXIII. to take refuge in Florence (June 1413), where that dangerous guest received a not very friendly welcome. Since John's most immediate need was now protection and assistance against his terrible opponent Ladislaus, he sent, towards the close of August 1413, Cardinals Chalant and Francesco Zabarella, together with the celebrated Greek Manuel Chrysoloras, to King Sigismund, and commissioned them to determine the time and place of the forthcoming council. The agreement was soon concluded. On the 9th of December John XXIII. signed the bull convening the council at Constance, and pledged his papal support to them in perpetuity. It remained for John that his share in convening the synod would give him a certain right to regulate its proceedings, and that, by the aid of his numerous Italian prelates, he would be able to influence it more or less according to his views. But in this he was greatly deceived. So soon as he realized the true position of affairs he attempted to break up the council by his flight to Schaffhausen (March 20-21, 1415)—a project in which he would doubtless have succeeded but for the sagacity and energy of Sigismund.

In spite of everything, the excitement in Constance was unabated. In the midst of the confusion, which reigned supreme in the council, the upper hand was gained by that party which held that the only method by which the schism could be ended and a reformation of ecclesiastical discipline ensured was a drastic limitation of the papal privileges. The limitation was to be effected by the general council: consequently, the pope must be brought under the jurisdiction of that council, and—in the opinion of many—remain under its jurisdiction for all time. Thus, in a general concordat, with characteristic precipitation, an ecumenical council could not be dissolved or set aside by the pope, without its consent: the corollary to which was, that the present council, notwithstanding the flight of John XXIII., continued to exist in the full possession of its powers, and that, in matters pertaining to belief and the eradication of schism, all men—even the pope—were bound to obey the general council, whose authority extended over all Christians, including the pope himself.

By these decrees—which created as the supreme authority within the Church a power which had not been appointed as such by Christ1—the members of the council of Constance sought to give their position a theoretical basis before proceeding to independent action against the pope. But these declarations as to the superiority of an ecumenical council never attained legal validity, in spite of their defence by Pierre d'Ailly and Gerson. Emanating from an assembly without a head, which could not possibly be an ecumenical council without the assent of one of the popes (of whom one was necessarily the legitimate pope)—a council composed of the cardinals, by a majority of persons for the most part unqualified, and in a fashion which was thus distinctly different from that of the old councils—they can only be regarded as a coup de main, a last resort in the universal confusion. On the 20th of May the council deposed John XXIII.

The legitimate pope, Gregory XII., now consented to resign, but under strict reservation of the legality of his pontificate.

1 Here of course the author speaks of the papal supremacy and not of papal infallibility in matters of faith and morals—a doctrine which was formally declared a dogma of the Church only at the Vatican council in 1870. [Ed.]
by the great jubilee of 1413. At the same time the crowning reward of his labours was the effacing of the last traces of the schism. He prosecuted successfully the conflict with the adherents of Benedict XIII., who, till the day of his death
to the remnants of his usurped authority (see BENEDICT XIII.).
An attempt on the part of Alphonso V. of Aragon to renew the schism failed; and, in 1429, the Spaniard
was compelled to give up his anti-pope, Clement VIII. Count John
of Armagnac, whom Martin had excommunicated as a protector
of schismatics, was also driven to make submission. Martin
rendered the greatest service by his admission of a whole series
of distinguished men into the College of Cardinals; but he was
less fortunate in his struggles against Hussitism. His death
took place on the 20th of February 1431, and the inscription
on his grave—still preserved in the Lateran church—styles him
"the felicity of his age" (temporum suorum felicitas).

The Colonna pope was followed by the strict, moral
and pious Gabriel Conduimarco, under the title of Eugenius IV.

Eugenius IV.
1431-1447

The pontificate was not altogether happy. At the very
first, his violent and premature measures against the
Colonna family, which had received such unbounded
favour from his predecessor, embroiled him in a
sanguinary feud. Far worse, however, were the
conflicts which Eugenius had to support against the Council
of Basel—already dissolved on the 18th of December 1431.
At the beginning, indeed, a reconciliation between the pope
and council was effected by Sigismund who, on the 31st of May
1433, was crowned emperor at Rome. But, as early as the 29th
of May 1434 a revolution broke out in Rome, which, on the 4th
of June, drove the pope in flight to Florence; where he was
obliged to remain, while Giovanni Vitelleschi restored order in
that papal state.

The migration of Eugenius IV. to Florence was of extreme
importance; for this town was the real home of the new art,
and the intellectual focus of all the humanistic movements
in Italy. At Florence the pope came into closer contact with the
humanists, and to this circumstance is due the gradual
dominance which they attained in the Roman Curia—a domina-
cence which, both in itself, and even more because of the
frankly pagan leanings of many in that party, was bound to
awaken serious misgivings.

The Italian troubles, which had entailed the exile of
Eugenius IV., were still insignificant in comparison with those
conjured up by the fanatics of the Council in Basel. The
decrees enacted by that body made deep inroads on the rights of
the Latin Church, and the conflict increased in violence. On the
31st of July 1437 the fathers of Basel summoned Eugenius IV.
to appear before their tribunal. The pope retorted on the
18th of September by transferring the scene of the council to
Ferrara—afterwards to Florence. There, in July 1439, the union
with the Greeks was effected: but it remained simply a paper
agreement. On the 25th of June 1439 the synod—which
had already pronounced sentence of heresy on Eugenius IV.,
by reason of his obstinate disobedience to the assembly of
the Church—formally deposed him; and, on the 5th of
November, a rival pontiff was elected in the person of
the ambitious Amadeus of Savoy, who now took the
name of Felix V. (See BASIL, COUNCIL OF, and
FELIX V.) Thus the assembly of Christendom at
Basel had resulted not in the reformation of the Church, but
in a new schism! This, in fact, was an inevitable sequel to
the attempt to overthrow the monarchical constitution of the
Church. The anti-pope—the last in the history of the papacy
—made no headway, although the council invested him with the
power of levying annates to a greater extent than had ever
been claimed by the Roman Curia.

The crime of this new schism was soon to be expiated by its
perpetrators. The disincarnation of sovereigns and peoples
to a division, of the disastrous consequences of which the West
had only lately had plentiful experiences, was so pronounced that
the violent proceeding of the Basel fathers alienated from them
1 May 23, 1423; vide the Chronicle of Martin de Alparti, edited
by Ehrlie (1906).
Rome became the scene of a ***chronique scandaleuse*** among these scholars, there was something unnatural in the predominance of the humanists in the Curia.

The fostering care of the science-loving pope extended also to the field of ecclesiastical literature; and the greatest importance attaches to the energy he developed as a collector of manuscripts and books. His agents travelled as far as Prussia, and even into the East. All this activity served to enrich the Vatican library, the foundation of which is for Nicholas V, an abiding title to fame. In political and ecclesiastical affairs he similarly manifested great vigour; and his extraordinarily pacific disposition did more than anything else towards diminishing the difficulties with which he had to contend on his entry upon office. An agreement was very quickly concluded with King Alphonso of Naples. In the Empire the affairs of the Church were ameliorated—though not so quickly—by the Concordat of Vienna (1448). The Council of Basel was compelled to dissolve, and the anti-pope Felix V. to abdicate: and, though even after the termination of the synod men like Jacob of Jüterbog (q.v.) were found to champion ecclesiastical parliamentoarianism and the more advanced ideas of Basel, they were confronted, on the other hand, by an array of redoubtable controversialists, who entered the lists to defend, both in speech and writing, the privileges of the Apostolic See. Among these, Torquemada, Cardinal de Arveaux, Capistrano and Pietro del Monte were especially active for the restoration of the papacy. Fortunate as Nicholas was in the ***haute politique*** of the Church, he was equally so in his efforts to re-establish and maintain peace in Rome and the papal state. In Poland, Bohemia, Hungary, Bosnia and Croatia—even in Cyprus itself—he was zealous for the peace of the Church.

The long-hoped cessation of civil war within the Church had now come, and Nicholas considered that the event could not better be celebrated than by the proclamation of a universal jubilee—an announcement which evoked a thrill of joy in the whole of Christendom. A special point of attaction in this jubilee of 1450 was the canonization of Bernardino of Siena; and, in spite of the plague which broke out in Rome, the celebrations ran a brilliant course.

It was the wish of the pope that the jubilee should be followed by a revival of religious life in all Christian countries. To put this project into execution, the Church opened her ***treasures of grace,*** connected with the jubilee dispensation, for the peculiar benefit of those nations that had suffered most from the tumults of the last few decades, or were prevented from meeting the Eternal City. Nicholas, then, nominated his legate for Germany, and began the work of reformation by travelling through every province in Germany dispersing blessings. It was under Nicholas V. that the last imperial coronation was solemnized at Rome. There is a touch of tragedy in the fact that, in the following year, the pope saw his temporal sovereignty—even his life—threatened by a conspiracy hatched among the adherents of the pseudo-humanism. The prime mover in the plot, Stefano Porcaro, was executed. Nicholas had scarcely recovered from the shock, when news came of the capture of Constantinople by the Turks; and his efforts to unite the Christian powers against the Moslem failed. This darkened the evening of his life, and he died in the night of the 24–25th of March 1455. From the universal standpoint of history the significance of Nicholas's pontificate lies in the fact that he put himself at the head of the artistic and literary Renaissance. By this means he introduced a new epoch in the history of the papacy and of civilization: Rome, the centre of ecclesiastical life, was now to become the centre of literature and art.

The short reign of the Spaniard, Alphonso de Borgia, as Pope Calixtus III., is almost completely filled by his heroic efforts to arm Christendom for the common defence against Islam. Unfortunately all the warnings and admonitions of the pope fell on deaf ears, though he himself parted with his mitre and plate in order to equip a fleet against the Turks: The Mahommedans, indeed, were severely punished at Belgrade (1456), and in the sea-
was simply the non-Christian tendency of the Renaissance, standing as it did on a purely pagan basis—"the stench of heathendom," as Danie described it. In other respects Paul III. encouraged men of learning and the art of printing, and built the magnificent palace of San Marco, in which he established a noble collection of artistic treasures.

The long pontificate of the Franciscan Francesco della Rovere, under the title of Pope Sixtus IV., displays striking contrasts of light and shade; and with him begins the series of the so-called "political popes." It remains a lamentable fact that Sixtus IV. frequently subordinated the Father of Christendom to the Italian prince, that he passed all bounds in the preference of his own family, and in many ways deviated into all too worldly courses. The decay of ecclesiastical discipline grew to alarming proportions under Sixtus. During his reign crying abuses continued and grew in spite of certain reforms.

The nepotism in which the pope indulged is especially inexcusable. His feud with Lorenzo de' Medici culminated in the Pazzi conspiracy, the tragic sequel to which was the assassination of Giuliano de' Medici (April 26, 1478). That the pope himself was guiltless of any share in that atrocious deed is beyond dispute; but it is deeply to be regretted that his name plays a part in the history of this conspiracy. Sixtus was far from blind to the Turkish peril, but here also he was hampered by the indifference of the secular powers. Again, the close of his reign was marked by the wars against Ferrara and Naples, and subsequently against Venice and the Colonnes; and these drove the question of a crusade completely into the background.

In the affairs of the Church he favoured the mendicant orders, and declared against the cruel and unjust proceedings of the Spanish Inquisition. His nominations to the cardinalate were not happy. The College of Cardinals, and the Curia in general, grew more and more infected with worldliness during his pontificate. On the other side, however, the pope did splendid service to art and science, and allowed incredible freedom. The Vatican library was enriched and thrown open for public use, Platina—the historian of the popes—receiving the post of librarian. The city of Rome was transfigured. At the papal order there arose the Ponte Sisto, the hospital of San Spirito, Santa Maria del popolo, Santa Maria della pace, and finally the Sistine Chapel, for the decoration of which the most famous Tuscan and Umbrian artists were summoned to Rome. This fresco-cycle, with its numerous allusions to contemporary history, is still preserved, and forms the noblest monument of the Rovere pope.

The reign of Innocent VIII. is mainly occupied by his troubles with the faithless Ferdinand of Naples. These sprang from his participation in the War of the Barons; but to this Innocent VIII., 1484— the pope was absolutely compelled. Innocent's bull 1492 concerning witchcraft (Dec. 5, 1484) has brought upon him many attacks. But this bull contains no sort of dogmatic definition of the nature of sorcery. The very form of the bull, which merely sums up the various items of information that had reached the pope, is enough to prove that the decree was not intended to bind anyone to belief in such things. Moreover the bull contained no essentially new regulations as to witchcraft. It is absurd to make this document responsible for the introduction of the bloody persecution of witches; for, according to the Sachsenspiegel, the civil law already punished sorcery with death. The action of Innocent VIII. was simply limited to defining the jurisdiction of the inquisitors with regard to magic. The bull merely authorized, in cases of sorcery, the procedure of the canonical inquisition, which was conducted exclusively by spiritual judges and differed entirely from that of the later witch-trials. Even if the bull encouraged the persecution of witches, in so far as it encouraged the inquisitors to take earnest action, there is still no valid ground for the accusation that Innocent VIII. introduced the trial of witches and must bear the responsibility for the terrible misery which was afterwards brought on humanity by that institution.

During the last three decades of the 15th century the Roman Curia, and the College of Cardinals in particular, became increasingly worldly. This explains how the death of Innocent VIII. (July 25, 1492), simiaecal at 1492—1503. Alexander VI. 1492—503. intrigues succeeded in procuring the election of Cardinal Rodrigo Borgia, a man of the most abandoned morals, who did not change his mode of life when he ascended the throne as Pope Alexander VI. The beginning of his reign was not unpromising; but all too soon that nepotism began which attained its height under this Spanish pope, and dominated his whole pontificate. A long series of scandals resulted. The cardinals opposed to Alexander, headed by Giuliano della Rovere, found protection and support with Charles VIII. of France, who laid claim to Naples. In prosecution of this design the king appeared in Italy in the autumn of 1494, pursued his triumphant march through Lombardy and Tuscany, and, on the 31st of December, entered Rome. Charles had the word reform perpetually on his lips; but it could deceive none who were acquainted with the man. At first he threatened Alexander with deposition; but on the 15th of January 1495 an agreement was concluded between pope and king.

While the French were marching on Naples there arose a hostile coalition which compelled them to beat a hasty retreat—the Holy League of March 1495. All their conquests were lost; and the pope now determined to chastise the Orsini family, whose treachery had thrown him into the hands of the French. The project miscarried, and on the 25th of January 1497 the papal forces were defeated.

In June occurred the mysterious assassination of the duke of Gandia, which appeared for a while to mark the turning-point in Alexander's life. For some time he entertained serious thoughts of reformation; but the matter was first postponed and then forgotten. The last state now became worse than the first, as Alexander fell more and more under the spell of the infamous Cesare Borgia. One scandal followed hard on the other, and opposition naturally sprang up. Unfortunately, Savonarola, the head of that opposition, transgressed all bounds in his well-meaning zeal. He refused to yield the pope that obedience to which he was doubly pledged as a priest and the member of an order. Even after his excommunication (May 12, 1497) he continued to exercise the functions of his office, under the shelter of the secular arm. In the end he demanded a council for the deposition of the pope. His fall soon followed, when he had lost all ground in Florence; and his execution on the 23rd of May 1498 freed Alexander from a formidable enemy (see SAVONAROLA). From the Catholic standpoint Savonarola must certainly be condemned: mainly because he completely forgot the doctrine of the Church that the sinful and vicious life of superiors, including the pope, is not competent to abrogate their jurisdiction.

After the death of Charles VIII. Alexander entered into an agreement and alliance with his successor Louis XII. The fruits of this compact were reaped by Cesare Borgia, who resigned his cardinal's hat, became duke of Valentinois, annihilated the minor nobles of the papal state, and made himself the true dictator of Rome. His soaring plans were destroyed by the death of Alexander VI., who met his end on the 18th of August 1503 by the Roman fever—not by poison.

The only bright pages in the dark chapter of Alexander's popedom are his efforts on behalf of the Turkish War (1499-1502), his activity for the diffusion of Christianity in America, and his judicial awards (May 3-4, 1493) on the question of the colonial empires of Spain and Portugal, by which he avoided a bloody war. It is folly to speak of a donation of lands which did not belong to the pope, or to maintain that the freedom of the Americans was extinguished by the decision of Alexander VI. The expression "donation" simply referred to what had already been won under just title: the decree contained a deed of gift, but it was an adjustment between the powers concerned and the other European princes, not a parcelling out of the New World and its inhabitants. The monarchs on whom the privilege was conferred received a right of priority with
PAPACY

[1305-1590]

respect to the provinces first discovered by them. Precisely as to-day inventions are guarded by patents, and literary and artistic creations by the law of copyright, so, at that period, the papal bull and the protection of the Roman Church were an effective means for ensuring that a country should reap where she had sown and should maintain the territory she had discovered and conquered by arduous efforts; while other claimants, with predatory designs, were warned back by the ecclesiastical censorship. In the Vatican the memory of Alexander VI. is still perpetuated by the Appartamenta Borgia, decorated by Pinturicchio with magnificent frescoes, and since restored by Leo XIII.

The short reign of the noble Pius III. (Sept. 22—Oct. 18, 1503) witnessed the violent end of Cesare Borgia's dominion. As early as the 1st of November Cardinal Giuliano della Rovere was elected by the conclave as Julius II. He was one of those personalities in which everything transcends the ordinary scale. He was endowed with great force of will, indomitable courage, extraordinary acumen, heroic constancy and a discriminating instinct for everything beautiful. A nature formed on great broad lines—a man of spontaneous impulses carrying away others as he himself was carried away, a genuine Latin in the whole of his being—he belongs to those imposing figures of the Italian Renaissance whose character is summarized in contemporary literature by the word terrible, which is best translated "extraordinary" or "magnificent."

As cardinal Julius II. had been the adversary of Alexander VI., as pope he stood equally in diametrical opposition to his predecessor. The Borgia's foremost thought had been for his family; Julius devoted his effort to the Church and the papacy. His chief idea was to revive the world-dominion of the popedom, but first to secure the independence and prestige of the Holy See on the basis of a firmly established and independent territorial sovereignty. Thus two problems presented themselves: the restoration of the papal state, which had been reduced to chaos by the Borgias; and the liberation of the Holy See from the onerous dependence on France—in other words, the expulsion of the French "barbarians" from Italy. His solution of the first problem entitles Julius II. to rank with Innocent III. and Cardinal Albornoz as the third founder of the papal state. His active prosecution of the second task made the Rovere pope, in the eyes of Italian patriots, the hero of the century. At the beginning of the struggle Julius had to endure many a hard blow; but his courage never failed—or, at most, but for a moment—even after the French victory at Ravenna, on Easter Sunday 1512. In the end the Swiss saved the Holy See; and, when Julius died the power of France had been broken in Italy, although the power of Spain had taken its place.

The conflict with France led to a schism in the College of Cardinals, which resulted in the conciliabulum of Pisa. Julius adroitly checkmated the cardinals by convening a general council, which was held in the Lateran. This assembly was also designed to deal with the question of reform, when the pope was summoned from this world (Feb. 20—21, 1513). Of his ecclesiastical achievements the bull against simony at papal elections deserves the most honourable mention. Again, by his restoration of the papal state, after the frightful era of the Borgias, Julius became the saviour of the papal power. But this does not exhaust his significance; he was, at the same time, the renewer of the papal Maecenas in the domain of art. It is to his lasting praise that he took into his service the three greatest artistic geniuses of the time— Bramante, Michelangelo and Raphael—and entrusted them with congenial tasks. Bramante drew out the plan for the new cathedral of St Peter and the reconstruction of the Vatican. On the 9th of April 1506 the first cornerstone of the new St Peter's was laid; 120 years later, on the 18th of November 1626, Urban VIII. consecrated the new cathedral of the world, on which twenty popes had laboured, in conjunction with the first architects of the day, modifying in many points the grandiose original design of Bramante, and receiving the contributions of every Christian land.

St Peter's, indeed, is a monument of the history of art, not merely within these 120 years from the zenith of the Renaissance till the transition into Baroque—from Bramante, Raphael, Michelangelo, to Maderna and Bernini—but down to the 19th century, in which Canova and Thorwaldsen erected there the last great papal monuments. But a still more striking period of art is represented by the Vatican, with its antique collections, the Sistine and the Stanze. Here, too, we are everywhere confronted with the name of Julius II. It was he who inaugurated the collection of ancient statues in the Belvedere, and caused the wonderful roof of the Sistine Chapel to be painted by Michelangelo (cf. Steinmann, Die sechste Kapelle II., 1905). Simultaneously, on the commission of the pope, Raphael decorated the Vatican with frescoes glorifying the Church and the papacy. In the Camera della Segnatura he depicted the four intellectual powers, theology, diplomacy, poetry and law. In the Stanza d'Eliodoro Julius II. was visibly extolled as the Head of the Church, sure at all times of the aid of Heaven.

As so often occurs in the history of the papacy, Julius II. was followed by a man of an entirely different type—Leo X. Though not yet 37 years of age, Giovanni de' Medici, distinguished for his generosity, mildness and courtesy, was elevated to the pontifical chair by the adroit maneuvres of the younger cardinals. His policy—though officially he declared his intention of following in the steps of his predecessor—was at first extremely reserved. His ambition was to play the rôle of peacemaker, and his conciliatory policy achieved many successes. Thus, in the very first year of his reign, he removed the schism which had broken out under Julius II. As a statesman Leo X. often walked by very crooked paths; but the reproach that he allowed his policy to be swarded exclusively by his family interests is unjustified. It may be admitted that he clung to his native Florence and to his family with warm affection; but the really decisive factor which governed his attitude throughout was his anxiety for the temporal and spiritual independence of the Holy See. The conquest of Milan by the French led to a personal interview at Bologna, where the "Concordat" with France was concluded. This document annulled the Pragmatic Sanction of Bourges, with its schismatic tendencies, but at the same time confirmed the preponderating influence of the king upon the Gallican Church—a concession which, in spite of its many dubious aspects at least made the sovereign the natural defender of the Church and gave him the strongest motive for remaining Catholic. The war for the duchy of Urbino (1516—17) entailed disastrous consequences, as from it dates the complete disorganization of papal finance. It was, moreover, a contributing cause of the conversion of Cardinal Petrucci, the suppression of which was followed (July, 1517) by the creation of 31 new cardinals in one day. This—the greatest of recorded creations—turned the scale once and for all in favour of the papal authority and against the cardinals. The efforts of Leo to promote a crusade, which fall mainly in the years 1517 and 1518, deserve all recognition, but very various opinions have been held as to the attitude of the pope towards the Imperial election consequent on the death of Maximilian I. The fundamental motive for his proceedings at that period was not nepotistic tendencies—which doubtless played their part, but only a secondary one—but his anxiety for the moral and temporal independence of the Holy See. For this reason Leo, from the very first, entertained no genuine desire for the selection either of Charles V. or Francis I. of France. By playing off one against the other he succeeded in holding both in suspense, and induced them to conclude agreements safeguarding the pope and the Medici. Of the two, the latter, of course, was the contesting interest. His history was first elucidated by Pastor, in his Geschichte der Päpste, vol. iii., which also contains the most complete account of the reign of this the second Rovere pope. —[Ed.]

Alfonso Petrucci (d. 1519), a Siennese. He was degraded from the cardinalate by Leo X. —[Ed.]
the French king appeared the less dangerous, and the result was that Leo championed his cause with all his energies. Not till the eleventh hour, when the election of the Habsburg, to whom he was entirely opposed, was seen to be certain did he give way. He thus at least avoided an open rupture with the new emperor—a rupture which would have been all the more perilous on account of the religious revolution now imminent in Germany. There the great secession from Rome was brought about by Martin Luther; but, in spite of his striking personality, the upheaval which was destined to shatter the unity of the Western Church was not his undivided work. True, he was the most powerful agent in the destruction of the existing order; but, in reality, he merely put the match to a pile of inflammable materials which had been collecting for centuries (see Reformation). A main cause of the cleavage in Germany was the position of ecclesiastical affairs, which—though by no means hopeless—yet stood in urgent need of emendation, and, combined with this, the deeply resented financial system of the Curia. Thus Luther assumed the leadership of a national opposition, and appeared as the champion who was to undertake the much-needed reform of abuses which clamoured for redress. The occasion for the schism was given by the conflict with regard to indulgences, in the course of which Luther was not content to attack actual grievances, but assailed the Catholic doctrine itself. In June 1518 the canonical proceedings against Luther were begun in Rome; but, owing to political influences, only slow progress was made. It was not till the 15th of June 1520 that his new theology was condemned by the bull Exsurge, and Luther himself threatened with excommunication—a penalty which was only enforced owing to his refusal to submit, on the 3rd of January 1521.

The state of Germany, together with the unwise behaviour of Francis I, compelled Leo X. to side with Charles V. against the French king; and the united forces of the empire and papacy had achieved the most brilliant success in upper Italy, when Leo died unexpectedly, on the 1st of December 1521. The character of the first Medician pope shows a peculiar mixture of noble and ignoble qualities. With an insatiable love of pleasure he combined a certain external piety and a magnificent generosity in his charities. His financial administration was disastrous, and led simply to bankruptcy. On music, hunting, expensive feasts and theatrical performances money was squandered, while, with unprecedented optimism the pope was blind to the deadly earnestness of the times.

Leo's name is generally associated with the idea of the Medicean era as a golden age of science and art. This conception is only partially justified. The reputation of a greater Maecenas—ascribed to him by his eulogists—dwindles before a sober, critical contemplation, and his undeniable merits are by no means equal to those which fame has assigned to him. The love of science and literature, which animated the son of Lorenzo the Magnificent, frequently took the shape of literary dilettantism. In many respects the brilliance of this long and often vaunted Maecenate of Leo X. is more apparent than real. There are times when it irresistibly conveys the impression of pleasing novelties of which the subject remains but in memory. The genuine significance of Leo lies rather in the stimulus which he gave. From this point of view his deserts are undoubtedly great; and for that reason he possesses an indefeasible right to a certain share in the renown of the papacy as a civilizing agent of the highest rank.

As a patron of art Leo occupies a more exalted plane. In this domain the first place must be assigned to the splendid achievements of Raphael, whom the pope entrusted with new and comprehensive commissions—the Stanza dell' incendio, the Logge, and the tapestry-cartoons, the originals of the last named being now in London. But, though illuminated by the rays of art, and loaded with the exuberant panegyrics of humanists and poets, the reign of the first Medicean pontiff, by its unbounded devotion to purely secular tendencies and its comparative neglect of the Church herself proved disastrous for the See of St Peter.

By a wonderful dispensation the successor to this scion of the Medici was Adrian VI.—a man who saw his noblest task, not in an artistic Maecenas, nor in the prosecution of political designs, but in the reform of the Church 1522-1523, in all its members. Careless of the glories of Renaissance art, a stranger to all worldly instincts, the earnest Netherlander inscribed on his banner the healing of the moral ulcers, the restoration of unity to the Church—especially in Germany—and the preservation of the West from the Turkish danger. How clearly he reads the causes of religious decadence, how deeply he himself was convinced of the need of trenchant reform, is best shown by his instructions to Chieregati, his nuncio to Germany, in which he laid the axe to the root of the tree with unheard-of freedom. Unfortunately, it was all in vain. Luther and his adherents overwhelmed the noble pope with unmeasured abuse. The two great rivals, Francis I. and Charles V., were deaf to his admonitions to make common cause against the Turks. The intrigues of Cardinal Soderini led to a breach with France and drove Adrian into the arms of the Imperial league. Soon afterwards, on the 14th of September 1523, he died. Long misunderstood and slandered, Adrian VI., the last German pope, is now by all parties ranked among the most revered and most worthy of the popes. No one now denies that he was one of those exceptional men, who, without self-seeking spend their lives in the service of a cause and fight bravely against the stream of corruption. Even though, in his all too brief pontificate, he failed to attain any definite results, he at least fulfilled the first condition of any cure by laying bare the seat of disease, gave an important impetus to the cause of the reform of the Church, and laid down the principles on which this was afterwards carried through. His activity, in fact, will always remain one of the brightest chapters in the history of the papacy.

Under Leo X. Cardinal Giulio de' Medici, the cousin of that pope, had already exercised a decisive influence upon Catholic policy; and the tiara now fell to his lot. Clement VII.—so the new pontiff styled himself—was soon driven over the weight of the crown which he had discovered. The international situation was the most difficult imaginable, and altogether beyond the powers of the timorous, vacillating and irresolute Medicean pope. His determination to stand aloof from the great duel between Francis I. and Charles V. failed him at the first trial. He had not enough courage and perspicacity to await in patience the result of the race between France and Germany for the duchy of Milan—a contest which was decided at Pavia (Feb. 24, 1525). The haughty victors found Clement on the side of their opponent, and he was forced into an alliance with the emperor (April 1, 1525). The overweening arrogance of the Spaniards soon drove the pope back into the ranks of their enemies. On the 22nd of May 1526 Clement acceded to the League of Cognac, and joined the Italians in their struggle against the Spanish supremacy. This step he was destined bitterly to repent. The tempest descended on the pope and on Rome with a violence which cannot be paralleled, even in the days of Alaric and Genseric, or of the Norman Robert Guiscard. On the 6th of May 1527 the Eternal City was stormed by the Imperial troops and the everlasting devastation in the famous sack. Clement was detained for seven months a prisoner in the castle of St Angelo. He then went into exile at Orvieto and Viterbo, and only on the 6th of October 1528 returned to his desolate residence. After the fall of the French dominion in Italy he made his peace with the emperor at Barcelona (June 29, 1529); in return for which he received the assistance of Charles in re-establishing the rule of the Medici in Florence. During the Italian turmoil the schism in Germany had made such alarming progress that it now proved impossible to bridge the chasm. With regard to the question of a council the pope was so obsessed by doubts and fears that he was unable to advance a single step; nor, till the day of his death could he break off his pitiful vacillation between Charles V. and Francis I. While large portions of Germany were lost to the Church the revolt from Rome proceeded apace in Switzerland.
and the Scandinavian countries. To add to the disasters, the divorce of Henry VIII. led to the English schism. Whether another head of the Church could have prevented the defection of England is of course an idle question. But Clement VII. was far from possessing the qualities which would have enabled him to show a bold front to the ambitious Cardinal Wolsey and the masterful and passionate Henry VIII. At the death of Clement (Sept. 25, 1534), the complete disruption of the Church seemed inevitable.

When all seemed lost salvation was near. Even in the reign of the two Medici popes the way which was to lead to better things had been silently paved within the Church. Under Leo X., himself there had been formed in Rome, in the Oratory of the Divine Love, a body of excellent men of strictly Catholic sentiments. It was by members of this Oratory—especially St. Gaetano di Tieni. Carafa (later Paul IV.), and the great bishop of Verona, Giberti—that the foundations of the Catholic reformation were laid. Under Clement VII. the establishment of new religious orders—Theatines, Somascanes, Barnabites and Capuchins—had sown the seeds of a new life in the ancient Church. The harvest was reaped during the long pontificate of the Saracens pope, Paul III. With his accession devotion to religion and the Church began to regain their old mastery. True, Paul III. was not a representative of the Catholic reformation, in the full sense of the words. In many points, especially his great nepotism—witness the promotion of the worthless Pier Luigi Farnese—he remained, even as pope, a true child of the Renaissance period in which he had risen to greatness. Nevertheless he possessed the necessary adaptability and acumen to enable him to do justice to the demands of the new age, which imperatively demanded that the interests of the Church should be the first consideration. Thus, in the course of his long reign he did valuable work in the cause of the Catholic reformation and prepared the way for the Catholic restoration. It was he who regenerated the College of Cardinals by levying it with men of ability, who took in hand the reform of the Curia, confirmed the Jesuit Order, and finally brought the Council of Trent into existence (Sessions I.—X. of the council, first period, 1545—1564). In order to check the progress of Protestantism in Italy Paul III. founded the Congregation of the Inquisition (1542). Political differences, and the transference of the council to Bologna in 1547, brought the pope into sharp collision with the emperor, who now attempted by means of the Interim to regulate the religious affairs of Germany according to his wishes—but in vain. The disobedience of his favourite Ottavio hastened the death of the old pope (Nov. 10, 1549).

Under the Farnese pope art enjoyed an Indian summer. The most important work for which he was responsible is the "Last Judgment" of Michelangelo in the Sistine Chapel. In 1547 Michelangelo was further entrusted with the superintendence of the reconstruction of St. Peter's. He utilized his power by rejecting the innovations of Antonio da Sangallo, saved the plan of Bramante, and left behind him sufficient drawings to serve the completion of the famous cupola. Titian painted Paul's portrait, and Guglielmo della Porta cast the bronze statue which now adorns his grave in St. Peter's.

After a protracted conclave Giovanni Maria del Monte was elected, on the 7th of February 1550, as Pope Julius III. He submitted to the emperor's demands and again convened the council (Sessions XI.—XVI. second period), but was obliged to suspend it on the 22nd of April 1552, in consequence of the war between Charles V. and Maurice of Saxony. From this time onwards the pope failed to exhibit requisite energy. In his beautiful villa before the Porta del Popolo he sought to banish political and ecclesiastical anxieties from his mind. Yet even now he was not wholly inactive. The religious affairs of England especially engaged his attention; and the nomination of Cardinal Pole as his legate to that country, on the death of Edward VI. (1553), was an extremely adroit step. That the measure was not the fault of Julius III., who died on the 23rd of March 1555.

PAPACY

The feeble régime of Julius had made it evident that a pope of another type was necessary if the papal see were to preserve the moral and political influence which it had regained under Paul III. On the 10th of April 1555, after a conclave which lasted five days, the reform party secured the election of the distinguished Marcellus II.

Unfortunately, on the 1st of May, an attack of apoplexy cut short the life of this pope, who seemed peculiarly adapted for the reformation of the Church.

On the 23rd of May 1555 Gian Pietro Carafa, the strictest of the strict, was elected as his successor, under the title of Paul IV. Though already 79 years of age, he was animated by the fiery zeal of youth, and he employed the most drastic methods for executing the necessary reforms and combating the advance of Protestantism. Always an opponent of the Spaniards, Paul IV., in the most violent and impolitic fashion, declared against the Habsburgs. The conflict with the Colonna was soon followed by the war with Spain, which, in spite of the French alliance, ended so disastrously, in 1557, that the pope henceforward devoted himself exclusively to the internal affairs. The sequel was the end of the nepotism of Paul III. with the result that the papal government was in no way disturbed by the repression of the reform within the Church. Protestantism was successfully eradicated in Italy; but the pope failed to prevent the secession of England. After his death the rigour of the Inquisition gave rise to an insurrection in Rome. The Venetian ambassador says of Paul IV. that, although all feared his strictness, all venerated his learning and wisdom.

The reaction against the iron administration of Paul IV. explains the fact that, after his decease, a more worldly-minded pope was again elected in the person of Cardinal Giovanni Angelo de' Medici—Pius IV. In striking contrast to his predecessor he favoured the Habsburgs. A suit was instituted against the Carafa, and Cardinal Carafa was even executed. To his own relatives, however, Pius IV. accorded no great influence, the advancement of his distinguished nephew, Carlo Borromeo (q.v.) being singularly fortunate for the Church. The most important act of his reign was the reassembling of the Council of Trent (Sessions XVII.—XXV., third period, 1562—1563). It was an impressive moment, when, on the 4th of December 1563, the great ecumenical synod of the Church came to a close. Till the last it was obliged to contend with the most formidable difficulties: yet it succeeded in effecting many notable reforms and in illuminating and crystallizing the distinctive doctrines of Catholicism. The breach with the Protestant Reformation was now final, and all Catholics felt themselves once more united and brought into intimate connexion with the centre of unity at Rome (see TRENT, COUNCIL OF).

The three great successors of Pius IV. inaugurate the heroic age of the Catholic reformation and restoration. All three were of humble extraction, and sprang from the people in the full sense of the phrase. Pius V., formerly Michele Ghisleri and a member of the Dominican Order, observed even as pope the strictest rules of the brotherhood, and was already regarded as a saint by his contemporaries. For Rome, in especial, he completed the task of reform. The Cardinal of Ferrara was a man of formidable character, and once more became a rallying point for men of stainless character, so that it produced a profound impression even on non-Catholics; while the original methods of St. Philip Neri had a profound influence on the reform of popular morals.

In the rest of Italy also Pius V. put into execution the reformational decrees of Trent. In 1566 he gave publicity to the Tridentine catechism; in 1588 he introduced the amended Roman breviary; everywhere he insisted on strict monastic discipline, and the compulsory residence of bishops within their sees. At the same period Carlo Borromeo made his diocese of Milan the model of a reformed bishopric. The pope supported Mary Stuart with money; his troops assisted Charles IX. of France against the Huguenots, and he lent his aid to Philip II. against the Calvinists of the Netherlands. But his greatest joy was that he succeeded where Pius II. had failed, despite all his efforts,
by bringing to a head an enterprise against the Turks—then masters of the Mediterranean. He negotiated an alliance between the Venetians and Spaniards, contributed ships and soldiers, and secured the election of Don John of Austria to the supreme command. He was privileged to survive the victory of the Christians at Lepanto; but on the 1st of May in the following year he died, as piously as he had lived. The last pope to be canonized, his pontificate marks the zenith of the Catholic reformation.

The renewed vigour which this internal reformation had infused into the Church was now manifest in its external effects; and Pius V., the pope of reform, was followed by the popes of the Catholic restoration. These, without interrupting the work of reformation, endeavoured by every means to further the outward expansion of Catholicism. On the one hand missions were despatched to America, India, China and Japan; on the other, a strenuous attempt was made to reannex the conquests of Protestantism. In a word, the age of the Catholic restoration was beginning—a movement which has been misnamed the counter Reformation. In this period, the newly created religious orders were the right arm of the papacy, especially the Jesuits and the Capuchins. In place of the earlier supineness, the battle was now joined all along the line. Everywhere, in Germany and France, in Switzerland and the Low Countries, in Poland and Hungary, efforts were made to check the current of Protestantism and to re-establish the orthodox faith. This activity extended to wider and wider areas, and enterprises were even set on foot to regain England, Sweden and Russia for the Church. This universal outburst of energy for the restoration of Catholicism, which only came to a standstill in the middle of the 17th century, found one of its most zealous promoters in Ugo Boncompagni—Pope Gregory XIII. Though not of an ascetic nature, he followed unwaveringly in the path of his predecessors by consecrating his efforts to the translation of the reformatory decrees into practice. At the same time he showed himself anxious to further the cause of ecclesiastical instruction and Catholic science. He created a special Congregation to deal with ecclesiastical affairs, and organized the Congregation of the Index, instituted by Pius V. On behalf of the diffusion of Catholicism throughout the world he spared no efforts; and wherever he was able he supported the great restoration. He was especially active in the erection and encouragement of educational institutions. In Rome he founded the splendid College of the Jesuits; and he patronized the Collegium Germanicum of St Ignatius; while, at the same time, he found means for the endowment of English and Irish colleges. In fact, his generosity for the cause of education was so unbounded that he found himself in financial difficulties. Gregory did good service, moreover, by his reform of the calendar which bears his name, by his emended edition of the Corpus juris canonici and by the creation of nuncialates. That he celebrated the centenary of St Bartholomew was a token that, according to his information, the step was a last resort to ensure the preservation of the royal family and the Catholic religion from the attacks of the revolutionary Huguenots. In his political enterprises he was less fortunate. He proved unable to devise a common plan of action on the part of the Catholic princes against Elizabeth of England and the Turks; while he was also powerless to check the spread of brigandage in the papal state.

On the death of Gregory XIII, Felice Peretti, cardinal of Montalto, a member of the Franciscan order, ascended the Apostolic throne as Sixtus V. (April 1585-August 1590). His first task was the extirpation of the bandits and the restoration of order within the papal state. In the course of a year the drastic measures of this born ruler made this state the safest country in Europe. He introduced a strictly ordered administration, encouraged the sciences, and enlarged the Vatican library, housing it in a splendid building erected for the purpose in the Vatican itself. He was an active patron of agriculture and commerce: he even interested himself in the draining of the Pontine marshes. The financial system he almost completely reorganized. With a boldness worthy of Julius II, he devised the most gigantic schemes for the annihilation of the Turkish Empire and the conquest of Egypt and Palestine. Elizabeth of England wished to restore to the Roman obedience either by conversion or by force; but these projects were shattered by the destruction of the Spanish Armada. Down to his death the pope kept a vigilant eye on the troubles in France. Here his great object was to save France for the Catholic religion, and, as far as possible, to secure her position as a power of the first rank. To this fundamental axiom of his policy he remained faithful throughout all vicissitudes.

In Rome itself Sixtus displayed extraordinary activity. The Pincian, the Esquiline, and the south-easterly part of the Caelian hills received essentially their present form by the creation of the Via Sistina, Felice, delle Quattro Fontane, di Sta Croce in Gerusselhene, &c.; by the buildings at Sta Maria Maggiore, the Villa Montalto, the reconstruction of the Lateran, and the aqueduct of the Felice, which partially utilized the Alexandrians and cost upwards of 300,000 scudi. The erection of the obelisks of the Vatican, the Lateran, the Piazza del Popolo and the square behind the tribune of Sta Maria Maggiore lent a lustre to Rome which no other city in the world could rival. The columns of Trajan and Antoninus were restored and bedecked with gilded statues of the Apostles; nor was this the only case in which the high-minded pope made the monuments of antiquity subservient to Christian ideas. His principal architect was Domenico Fontana, who, in conjunction with Guglielmo della Porta, completed the uniquely beautiful cupola of St Peter's which had already been designed by Michelangelo in a detailed model. In Santa Maria Maggiore the pope erected the noble Sistine Chapel, in which he was laid to rest. Indeed, the monumental character of Rome dates from this era. The organizing activity of Sixtus V. was not, however, restricted to the Eternal City, but extended to the whole administration of the Church. The number of cardinals was fixed at seventy-six bishops, fifty priests and fourteen deacons. In 1588 followed the new regulations with respect to the Roman Congregations, which henceforth were to be fifteen in number. Thus the pope laid the foundations of that wonderful and silent engine of universal government by which Rome still rules the Catholics of every land on the face of the globe.

When we reflect that all this was achieved in a single pontificate of but five years' duration, the energy of Sixtus V. appears simply astonishing. He was, without doubt, by far the most important of the post-Tridentine popes, and his latest biographer might well say that he died overweighted with services to the Church and to humanity.

(L. V. P.)

IV.—Period from 1590 to 1870.

The history of the papacy from 1590 to 1870 falls into four main periods: (1) 1590-1648; territorial expansion, definitely checked by the peace of Westphalia; (2) 1648-1789; waning prestige, financial embarrassments, futile reforms; (3) 1789-1814: revolution and Napoleonic reorganization; (4) 1814-1870: restoration and centralization.

1. 1590-1648. The keynote of the counter Reformation had been struck by the popes who immediately preceded this period. They sought to reconquer Europe for the Roman Catholic Church. In the overthrow of the Spanish Armada they had already received a great defeat; with the Peace of Westphalia the Catholic advance was baffled. Sixtus V. was succeeded in rapid succession by three popes: Urban VII., who died on the 27th of September 1590, after a papacy of only 12 days; Gregory XIV. (Dec. 1590 to Oct. 1591); Innocent IX. (Oct. to Dec. 1591).

The first noteworthy pontiff of the period was Clement VIII., who gained a vast advantage by allying the papacy with the rising power of France. Since 1559 the popes had been without exception in favour of Spain, which, firmly possessed of Milan on the north and of Naples,
on the south, held the States of the Church as in a vice, and thereby dominated the politics of the peninsula. After Henry IV., had taken Paris at the price of a mass, it became possible for the pope to play off the Bourbons against the Habsburgs, but the transfer of favour was made so gradually that the opposition of the papacy to Spain did not become open till just before Clement VIII. passed off the stage. His successor, Leo XI., undisguisedly French in sympathy, reigned but twenty-seven days—a sorry return for the 300,000 ducats which his election is rumoured to have cost Henry IV. Under Paul V. Rome was successful in some minor negotiations with Savoy, Genoa, Tuscany and Naples; but Venice, under the leadership of Paolo Sarpi (q.v.), proved unbending under ban and interdict: the state defiantly upheld its sovereign rights, kept most of the clergy at their posts, and expelled the recalcitrant Jesuits. When peace was arranged through French mediation in 1607 the papacy had lost greatly in prestige: it was evident that the once terrible interdict was antiquated, wherefore it has never since been employed against the entire territory of a state.

During the second and third decades of the 17th century the most coveted bit of Italian soil was the Valtelline. If Spain could gain this Alpine valley her territories would touch those of Austria, so that the Habsburgs north of the Alps could send troops to the aid of their Spanish cousins against Venice and Spain in turn could help to subdue the Protestant princes of Germany in the Thirty Years' War (1618–1648). From the Grisons, who favoured France and Venice, Spain seized the Valtelline in 1620, incidentally uprooting heresy there by the massacre of six hundred Protestants. Paul V. repeatedly lamented that he was unable to oppose such Spanish aggressions without extending protection to heretics. This scruple was, however, not shared by his successor, Gregory XV., who secured the consent of the powers to the occupation of the Valtelline by papal troops, a diplomatic victory destined, however, to lead ere long to humiliation. Gregory's brief but notable pontificate marks nevertheless the high-tide of the counter Reformation. Not for generations had the prospects for the ultimate annihilation of Protestantism been brighter. In the Empire the collapse of the Bohemian revolt led ultimately to the merciless repression of the Evangelicals in Bohemia (1627), and in the hereditary lands of Austria (1628), as well as to the transference of the electoral dignity from the Calvinistic elector of the Palatinate to the staunchly Catholic Kings of Burgundy.

In France the Huguenots threatened by a union of almost all their military power, a process completed by the fall of La Rochelle in 1628. In Holland the expiration of the Twelve Years' Truce in 1621 forced the Dutch Protestants once more to gird on the sword. England, meanwhile, was isolated from her co-religionists. King James I., who had coquetted twenty years previously with Clement VIII., and then had avenged the Gunpowder Plot (1605) by the most stringent regulation of his Roman Catholic subjects, was now dazzled by the project of the Spanish marriage. The royal dupe was the last man in the world to check the advance of the papacy. That service to Protestantism was performed by Catholic powers jealous of the preponderance of the Habsburgs. In view of these antipathies the treaty of 1627 between France, Spain and the pope is but an episode: instructive, however, in that the project, originated apparently by the pope, provided that England should be dismembered, and that Ireland should be treated as a papal fief. The true tendency of affairs manifested itself in 1630, when the emperor Ferdinand II. (1619–1637), at the zenith of his fortunes, forced the Protestant princes of Germany to restore to the Roman hierarchy all the ecclesiastical territories they had secularized during the past seventy-five years. Then France, freed from the fear of domestic enemies, arose to help the heretics to harry the house of Habsburg. Arranging a truce between Poland and Sweden, she unleashed Gustavus Adolphus. Thus by diplomacy as well as by force of arms Catholic France made possible the continued existence of a Protestant Germany, and helped to create the balance of power between Catholic, Lutheran and Reformed within the Empire, that, crystallized in the Peace of Westphalia, fixed the religious boundaries of central Europe for upwards of two centuries.

If it was Richelieu and not the pope who was the real arbiter of destinies from 1624 to 1642, Urban VIII. was usually content. In Italy he supported France against Spain in the controversy over the succession to Mantua (1627–1632–1644). In the Empire he manifested his antipathy to the overshadowing Habsburgs by plotting for a time to carry the next imperial election in favour of Bavaria. He is said to have rejoiced privately over Swedish victories, and certainly it was unerring instinct which told him that the great European conflict was no longer religious but dynastic. Anti-Spanish to the core, he became the greatest papal militarist since Julius II.; but Tuscany, Modena and Venice checkmated him in his ambitious attempt to conquer the duchy of Parma. Like most of the papal armies of the last three centuries, Urban's troops, distinguished themselves by wretched strategy, cowardice in rank and file, and a Fabian avoidance of fighting which, discreet as it may be in the field of diplomacy, has invariably failed to save Rome on the field of battle.

The States of the Church were enlarged during this period by the cession of two important fiefs—namely, Ferrara (1598) and Urbino (1611). Increase of territory, so far from filling the papal treasury, but postponed for the moment the progressive pauperization of the people. After annexation, the city of Ferrara sank rapidly from her perhaps artificial prosperity to the dead level, losing two-thirds of her population in the process. The financial difficulties of Italy were due to many causes, notably to a shifting of trade routes; but those of the papal states seem caused chiefly by misgovernment. Militarism may account for much of the tremendous deficit under Urban VIII.; but the real cancer was nepotism. The disease was inherent in the body politic. Each pope, confronted by the spectre of feudal anarchy, felt he could rely only on those utterly dependent on himself; consequently he raised his own relations to wealth and influence. This method had helped the House of Valois to consolidate its power; but what was tonic for a dynasty was death to a state whose headship was elective. The relations of one pope became the enemies of the next; and each pontiff governed at the expense of his successors. Under Clement VIII., the Aldobrandini, more splendidly under Paul V., the Barberini, with every hand at the short-lived Gregory XV., the Ludovisi, with unparalleled power under Urban VIII., the Barberini enriched themselves from a chronically depleted treasury. To raise money offices were systematically sold, and issue after issue of the two kinds of monti-securities, which may be roughly described as government bonds and as life annuities, was marketed at ruinous rates. More than a score of years after the Barberini had dropped the reins of power Alexander VII. said they alone had burdened the state with the payment of 480,000 scudi of annual interest, a tremendous item in a budget where the income was perhaps but 2,000,000. For a while interest charges consumed 8½% of the income of the government. Skillful refunding postponed the day of evil, but cash on hand was too often a temptation to plunder. The financial woes of the next period, which is one of decline, were largely the legacy of this age of glory.

The common people, as always, had to pay. The farming of exorbitant taxes, coupled as it was too often with dishonest concessions to the tax farmer, made the over-burdened peasant drink the doubly bitter cup of exploitation and injustice. Economic distress increased the number of highway robbers, then the turn lamen, unmerited retribution. Urban VIII. publicized the plunder of the papacy. The tale of these glories, with their attendant woes, does not exhaust the history of the papacy. Not as diplomats, not as governors, but as successive heads of a spiritual kingdom, did the popes win their grandest triumphs. At a time when the non-Catholic theologians were chiefly small fry, bent on
petty or sulphurous polemics, great Jesuit teachers like Bellarmine (d. 1621) laid siege to the very foundations of the Protestant faith. These thinkers performed for the unity of the faith in France and in the Catholic states of Germany services of transcendent merit, exceeding far in importance those of their flourishing allies, the Inquisitions of Spain, Italy, and of the Spanish Netherlands (see Inquisition). But the most fundamental spiritual progress of the papacy was made by its devoted missionaries. While the majority of Protestant leaders left the conversion of the heathen to some remote and inscrutable interposition of Providence, the Jesuits, Franciscans, Dominicans and kindred orders were busily engaged in making Roman Catholics of the nations brought by Oriental commerce or American colonial enterprise into contact with Spain, Portugal and France. Though many of the spectacular triumphs of the cross in Asia and Africa proved to be evanescent, nevertheless South America stands the impressive memorial of the greatest forward movement in the history of the papacy: a solidly Roman continent.

2. 1648-1796. From the close of the Thirty Years' War to the outbreak of the French Revolution the papacy suffered abroad enormous loss of prestige at home, perpetual financial embarrassment accompanied by a series of inadequate governmental reforms; and in the world at large, gradual diminution of reverence for spiritual authority. From slow beginnings these factors kept gaining momentum until they compassed the overthrow of the mighty order of the Jesuits, and culminated in the revolutionary spoliation of the Church.

At the election of Innocent X. (1644-1655) the favour of the Curia was transferred from France, where it had rested for over forty years, to the House of Habsburg, where it remained, save for the brief reign of Clement IX. (1667-1669), for half a century. The era of tension with France coincides with the earlier years of Louis XIV. (1663-1715); its main causes were the Jansenist and the Gallican controversies (see Jansenism and Gallicanism). The French crown was willing to sacrifice the Jansenists, who disturbed that dead level of uniformity so grateful to autocrats; but Gallicanism touched its very prerogatives, and was a point of honour which could never be abandoned without the possibility of the present government being put in 1672, led up to the classic declaration of the Gallican clergy of 1682; and, when aggravated by a conflict over the immunity of the palace of the French ambassador at Rome, resulted in 1688 in the suspension of diplomatic relations with Innocent XI., the imprisonment of the papal nuncio, and the seizure of Avignon and the Venaissin. So pronounced an enemy of French preponderance did Innocent become that he approved the League of Augsburg, and was not sorry to see the Catholic James II., whom he considered a tool of Louis, thrust from the throne of England by the Protestant William of Orange. Fears of the coalition, however, led the Grand Monarch to make peace with Innocent XII. (1691-1700). The good relations with France were but a truce, for the Bourbon powers became so mighty in the 18th century that they practically ignored the territorial interests of the papacy. Thus Clement XI. (1700-1721), who espoused the losing Habsburg side in the War of the Spanish Succession, saw his nuncio excluded from the negotiations leading to the Peace of Utrecht, while the lay signatories disposed of Sicily, the heel of his kingdom. Similarly Clement XII. (1730-1740) looked on impotently when the sudden Bourbon conquest of Naples in the War of the Polish Succession set at nought his claims to feudal sovereignty, and established Tanucci as minister of justice, a position in which for forty-three years he regulated the relations of church and state after a method most repugnant to Rome. No better fared Clement's medieval rights to Parma; nor could the sagacious and popular Benedict XIV. (1740-1758), who refused to press obsolete claims, either keep the foreign armies in the War of the Austrian Succession from trespassing on the States of the Church or prevent the ignoring at the Peace of Aix-la-

Chapelle of the papal overlordship over Parma and Piacenza. In fact, since the doctrinaire protest of Innocent X. against the Peace of Westphalia, at almost every important settlement of European boundaries the popes had been ignored or otherwise snubbed. Not for two centuries had the political prestige of the papacy been lower. Moreover, a feeling of revulsion against the Jesuits was sweeping over western Europe: they were accused of being the incarnation of the most baneful principles, political, intellectual, moral; and though Clement XIII. (1758-1760) protected them against the pressure of the Bourbon courts, his successor Clement XIV. (1760-1774) was forced in 1773 to disband the army of the Black Pope (see Jesuits). The sacrifice of these trusted soldiers failed however to stave the threat of the new age. Pius VI. (1775-1799), was treated with scant respect by his neighbours. Naples refused him tribute; Joseph II. of Austria politely but resolutely introduced fundamental Gallican reforms ("Josephism"); in 1786 at the Synod of Pistoia (p.v.) Joseph's brother Leopold urged similar principles on Tuscany, while in Germany the very archbishops were conspiring by the Punctum of Ems to aggrandize themselves like true Febronians, at the expense of the pope (see Febronianism). The attempt was rendered vain outside the Habsburg dominions, by the revolution; and to the Habsburg dominions the clerical revolution of 1790 caused the loss of what is to-day Belgium. However, the deluge which shattered the opposition to Rome in the great national churches submerged for a time the papacy itself.

In the States of the Church, during the first part of the period the outstanding feature in the history of the Temporal Power is the overthrow of nepotism; in the second, a dull conflict with debt. The chief enemies of nepotism were Alexander VII. (1655-1667), who dignified the secretariats of state and gave it its present pre-eminence by refusing to deliver it up to one of his relations; and Innocent XII. (1691-1700), whose bull Romanum decet pontificem ordered that no pope should make more than one nephew cardinal, and should not grant him an income over twelve thousand scudi. Thus by 1700 nepotic plunder had practically ceased, and with the exception of the magnificent peculium established by Clement X. (1669-1721), the central administration of finance has been usually considered honest. Nepotism, however, still left its scars upon the body politic, shown in the progressive decay of agriculture in the Campagna, causing Rome to starve in the midst of fertile but untilled nepotic latifundia. The fight against the legacy of debt was slower and more dreary. One pope, Innocent XII. (1700-1706), threatened at first with bankruptcy, managed to leave a surplus; but this condition, the product of severe economy and oppressive taxation, could not be maintained. In the 18th century it became necessary to resort to fiscal measures which were often harmful. Thus Clement XI., at war with Austria in 1708, debased the currency; Clement XII. (1730-1740) issued paper money and set up a government lottery, communicating all subjects who put their money into the lotteries of Genoa or Naples; Benedict XIV. (1740-1758) found stamped paper a failure; and Clement XIII. (1748-1759) made a forced loan. The stoppage of payments from Bourbon countries during the Jesuit struggle brought the annual deficit to nearly 100,000 scudi. Under Pius VI. (1775-1799) the emission of paper money, followed by an unsuccessful attempt to market government securities, produced a panic. By 1783 the taxes had been farmed for years in advance and the treasury was in desperate straits. Retrenchment often cut to the bone; wise reforms shattered on the inexperience or corruption of officials. Grand attempts to increase the national wealth usually cost the government more in fixed charges of interest than they yielded in rentals or taxes. The States of the Church, like France, were on the brink of bankruptcy. From this disgrace they were saved by a more eminent catastrophe—the Revolution.
The revolt against spiritual authority belongs rather to the history of modern thought than to that of the papacy. The intellectual movement against the Papacy by and against Revolution. What the Church heretics were still liable to torture, the relaxed to capital punishment; and in a backward country like Spain the single reign of Philip V. (1700-1746) had witnessed the burning of over a thousand heretics. If ecclesiastical authority fostered what was commonly regarded as intolerant obscurantism, to be enlightened meant to be prepared in spirit for that reform which soon developed into the Revolution.

3. 1789-1814. In the decade previous to the outbreak of the French Revolution the foreign policy of Pius VI. had been directed chiefly against decentralization, while his chief aim at home was to avoid bankruptcy by increasing his income. From 1789 on the French situation absorbed his attention. France, like the States of the Church, was facing financial ruin; but France did what the government of priests could not: namely, saved the day by the confiscation and sale of ecclesiastical property. It was not the aim of the Constituent Assembly to pauperize or annihilate the Church; it purposed to reorganize it on a juster basis. These reforms, embodied in the Civil Constitution of the Clergy, were part of the new Fundamental Law of the kingdom. The majority of the priests and bishops refused to swear allegiance to what they held to be an invasion of the divine right of the hierarchy, and after some months of unfortunate indecision Pius VI. (1775-1799) formally condemned it. Thenceforward France treated the papacy as an inimical power. The sudden toleration of the non-Juring priests changed into sanguinary persecution. The harrying was halted in 1795; and soon after the directory had been succeeded by the consulate, the Catholic religion was re-established by the concordat of 1801. From 1790 on, however, the rising power of France had been directed against Rome. In September 1791 France annexed Avignon and the Venaissin, thus removing for ever that territorial pawn with whose threatened loss the French monarchs had for centuries disciplined their popes. In 1793 Hugon de Bassville (q.v.), a diplomatic agent of France, was murdered at Rome, a deed not avenged until the Italian victories of Bonaparte. In the peace of Tolentino (Feb. 1797) the pope surrendered his claims to Avignon, the Venaissin, Bologna, Ferrara and the Romagna; he also promised to disband his worthless army, to yield up certain treasures of art, and to pay a large indemnity. Bonaparte believed that after these losses the temporal power would collapse of its own weight; but so peaceful a solution was not to be. During republican agitation at Rome the French general Duphot was killed; a French army advanced on the city, and carried the aged pontiff a prisoner of war to Valence in Dauphine, where he died on the 29th of August 1799.

His successor Pius VII., elected at Venice on the 14th of the following March, soon entered Rome and began his reign auspiciously by appointing as secretary of state Ercole Consalvi (q.v.), the greatest papal diplomatist of the 19th century. The political juncture was favourable for a reconciliation with France. In the concordat of 1801 the papacy recognized the validity of the sales of Church property, and still further reduced the number of dioceses; it provided that the government should appoint and support the archbishops and bishops, but that the pope should confirm them; and France recognized the temporal power, though shorn of Ferrara, Bologna and the Romagna. The supplementary Organic Articles of April 1802, however, centralized the administration of the Church in the hands of the First Consul; and some of these one-sided regulations were considered by Rome to be minute and oppressive; nevertheless, the Napoleonic arrangements remained in force, with but brief exceptions, till the year 1905. The indignation of the pope and his advisers was not deep enough to prevent the ratification in 1803 of a somewhat similar concordat for the Italian Republic. In 1804 Pius consented to anoint Napoleon emperor, thus casting over a conquered crown the halo of legitimacy. The era of good feeling was, however, soon ended by friction, which arose at a number of points. At length, in 1809, Napoleon annexed the papal states; and Pius, who excommunicated the invaders of his territory, was removed to France. The captive was, however, by no means powerless; by refusing canonical institution to the French bishops he involved the ecclesiastical system of Napoleon in inextricable confusion. After the return from Moscow the emperor negotiated with his prisoner a new and more exacting concordat, but two months later the repentant pope abrogated this treaty and declared all the official acts of the new French bishops to be invalid. By this time Napoleon was tottering to his fall; shortly before the catastrophe of Elba he allowed the pope to return to the States of the Church. Pius entered Rome amid great rejoicing on the 24th of May 1814, a day which marks the beginning of a new era in the history of the papacy. In September of the same year, by the bull Sollicitudo omnium ecclesiarum, he constituted the Society of Jesus.

Though the relations with France dominated the papal policy during the revolutionary period, the affairs of Germany received no small share of attention. The peace of Lunéville (1801) established the French boundary at the Rhine; and the German princes who thereby lost lands west of the river were indemnified by the secularization of ecclesiastical lands. The scheme of readjustment, known as the Enactment of the Delegates of 1803, the Empire (Reichsdeputationshauptschluss) of 1803, secularized practically all the ecclesiastical states of Germany. Thus at one stroke there was broken the age-long direct political power of the hierarchy in the Holy Roman Empire; and the ultimate heir of the bulk of these lands was Protestant Prussia.

4. 1814-1870. The foreign policy of the papacy so long as conducted by Consalvi, or in his spirit, was supremely successful. From 1814 to 1830 Europe witnessed the restoration of the papacy of legitimate monarchy. The once exiled dynasties conscientiously re-established the legitimate Church, and both conservative powers made common cause against revolutionary tendencies. Throughout Europe the governing classes regarded this “union of throne and altar” as axiomatic. For the pope, as eldest legitimate sovereign and protagonist against the Revolution, Consalvi obtained from the Congress of Vienna the restitution of the States of the Church in practically their full extent. By concluding concordats with all the important Catholic powers save Austria he made it possible to crush Jansenism, Febronianism and Gallicanism. By bulls of circumcision, issued after consultation with various Protestant states of Germany, he rearranged their Catholic dioceses and reduced ecclesiastical influence. By the unifying fact he gained the good will of Great Britain, where before him no cardinal had set foot for two centuries, and secured that friendly understanding between the British government and the Vatican which has since proved so valuable to Rome. After Consalvi’s retirement, Leo XII. (1823-1829) continued his policy and secured further advantageous concordats. In the sixteen months’ reign of Pius VIII. (1829-1830) came the achievement of Catholic emancipation in England and the Revolution of 1830; and the pope departed from the principle of legitimacy by recognizing Louis Philippe as king of the French. The pontificate of Gregory XVI. (1831-1846) was singularly infelicitous. The controversy with Prussia about the education of children of whose parents but one was Roman Catholic led to the imprisonment of Droste-Vischering, archbishop of Cologne, and later of Dunin, archbishop of Gnesen-Posen; but the accession of the royal romanticist Frederick William IV. in 1840 brought a pacific reversal of the Prussian policy, sometimes
judged more benevolent than wise. In France agitation was directed chiefly against the Jesuits, active in the movement to displace ancient local catechisms and liturgies by the Roman texts, to enroll the laity in Roman confraternities, and to induce the bishops to visit Rome more frequently. To check this ultramontane propaganda the government secured from the papacy in 1845 the promise to close the Jesuit houses and novitiates in France.

In Italy, however, lay the chief obstacles to the success of all papal undertakings. The revolution of 1830, though somewhat tardily felt in the States of the Church, compelled Gregory to rest his rule on foreign bayonets. In return he was obliged to lend an ear to the proposals of France, and above all to those of Austria. This meant opposition to all schemes for the unification of Italy. In 1859 the Italian peninsula had been divided into seven small states. Besides the government of the papal states there were three kingdoms: Sardinia, Lombardo-Venetia and Naples; and three duchies: Parma, Modena, Tuscany. To these regions the Napoleonic régime had given a certain measure of unity; but Metternich, dominant after 1815, held Italy to be merely a geographical term. To its unification Austria was the chief obstacle. The papal duchies, Lombardo-Venetia and Naples; and the three duchies, whose rulers were Austrian princes; and she upheld the autocracy of the king of Naples and that of the pope against all revolutionary movements. To the Italian patriot the papacy seemed in league with the oppressor. The pope sacrificed the national aspirations of his subjects to his international relations as head of the Church; and he sacrificed their craving for liberty to the alliance with autocracy on which rested the continued existence of the temporal power. The dual position of the pope, as supreme head of the Church on earth and as a minor Italian prince, was destined to break down through its inherent contradiction; it was the task of Pius IX. to postpone the catastrophe.

The reign of Pius IX. falls into three distinct parts. Until driven from Rome by the republican agitation of 1848 he was a popular idol, open to liberal political views. From his return in 1850 to 1870 he was the reactionary ruler of territories menaced by the movement for Italian unity, and sustained only by French bayonets; yet he was interested enough in Italy in pointing out to an often incredulous world that most of the vaunted, intellectual and religious progress of the 19th century was but pestilent error, properly to be condemned by himself as the infallible vicegerent of God. The division of his career, from the loss of the temporal power to his death, inaugurates a new period for the papacy.

At the outset of his reign he faced a crisis. It was clear that he could not continue the repressive tactics of his predecessor. Pius IX., 1846-1878.

The Papacy in Italy and Europe were astir with the Liberal agitation, which in 1848 culminated in the series of revolutions of the Unitarian type, by which the settlement of 1815 was destined to be profoundly modified. Liberal churchmen in Italy, while rejecting Mazzini's dream of a republic, had evolved projects for attaining national unity while preserving the temporal power. The exiled abbé Vincenzo Gioberti championed an Italian confederacy under the presidency of the pope; and his pamphlet, in hand with the unity of the nation should go the unity of the faith. In allusion to medieval partisans of the papacy this theory was dubbed Neo-Guelphism. Towards such a solution Pius IX. was at first not unfavourably inclined, but the revolution of 1848 cured him of his Liberal leanings. In November of that year he fled in disguise from his capital to Gaeta, in the kingdom of Naples, and when French arms had made feasible his restoration to Rome in April 1850 he returned in a temperament of stubborn resistance to all reform; henceforth he was no longer open to the influence of men of the type of Rossi or Rossini, but took the inspiration of his policy from Cardinal Antonelli and the Jesuits. The same pope who had signalized his accession by carrying out a certain number of Liberal reforms set his name in 1864 to the famous Syllabus, which was in effect a declaration of war by the papacy against the leading principles of modern civilization (see SYLLABUS).

As from 1849 to 1870 the fate of the papacy was determined not so much by domestic conditions, which, save for certain slight ameliorations, were those of the preceding regimes, as by foreign politics, it is necessary to consider the relations of Rome with each of the powers in turn; and in so doing one must trace not merely the negotiations of kings and popes, but must seek to understand also the aims of parliamentary parties, which from 1848 on increasingly determine ecclesiastical legislation.

The chief ally of the papacy from 1849 to 1870 was France. The policy which made Louis Napoleon dictator forced him into mortal conflict with the republican parties; and Louis Napoleon the price of the parliamentary support of the Catholic church and the majority was high. Even before Napoleon's election as president, Failou, the Catholic leader, had promised to secure intervention in favour of the dispossessed pope. Napoleon, however, could not forget that as a young man he himself had vainly sought to obtain from Gregory XVI. those liberties which Pius IX. still refused to grant; he therefore essayed diplomacy, not arms. Nevertheless, to forestall the rescue of the pope by Austrian troops, he sent, in August 1849, an army corps under Oudinot to Civita Vecchia. By heading off reactionary Austria Napoleon hoped to conciliate the French Liberals; by helping the pope, to satisfy the Catholics; by concessions to be wrung both from Pius and from his Roman triumvirs, to achieve a bloodless victory. As neither party yielded, Oudinot listened to his Catholic advisers, attacked Rome, with which the French Republic was technically at peace—and was roundly repulsed by Garibaldi. To relieve their ignoble predicament the ministry hurried the Liberal diplomatist, Ferdinand de Lesseps, to Rome to prevent further conflict. At the moment when Lesseps had secured the signing of a treaty with the Roman Republic permitting peaceful occupation of the city by the French army, he was peremptorily recalled and Oudinot was as unexpectedly ordered to take the city by storm. This amazing reversal of policy was procured by the intrigues of Catholic diplomatists and German Jesuits, conveyed to Paris by Prince de la Tour d'Auvergne. For the honour of the army and the Church republican France thereupon destroyed the Roman republic. Napoleon lost 1200 in dead and wounded, actually never has a single reform on which he had insisted, and drew upon himself the later legislation that was to count perpetual guard over the Vatican. As the case of clerical censure had also to acquiesce in that "Roman campaign at home" that resulted in the Falloux Act of 1850, which in the name of liberty of education put the university in bondage to the bishops, mitigated against lay teachers, and the in secondary and primary schools, and set them under clerical control, made it ominously easy for members of religious congregations to become instructors of youth, and cut the nerve of the communal school system. That education was delivered up to the Church was partly the result of the terror inspired in the middle classes by the socialistic upheavals of 1848. The bourgeoisie sought the support of the clergy, and religion became as unfashionable among them as it had been among the nobility after 1793. Religion was thought to be part of a fashionable education, and the training of girls came almost exclusively into the hands of the religious orders and congregations. So long as the alliance of the autocratic empire and the clergy lasted (1852-1860), intellectual reaction reigned; the university professors, who hitherto and philosophy were suppressed. This alliance of the empire with the clergy was shaken by the Italian War of 1859, which resulted in the loss by the pope of two-thirds of his territories. Napoleon was evidently returning to the traditions of his youth, and in the September Convention of 1861 it looked as if he would abandon Rome to its manifest destiny. This solution was spoiled by the impatience of Garibaldi and the supineness of the Romans themselves. In 1867 Napoleon made himself once more guardian of the Holy See; but the wonders wrought by the new French chassepots at the battle of Mentana cost the friendship of Italy. Thereafter Napoleon was blindly staggering to his fall.
PAPACY

[1590-1870]

aimed at honour in upholding the pope, in driving the Austrian tyrant from Italy, in attacking Prussia. The Austrian support on which he relied confidently in 1850 proved delusive, for he could obtain nothing from Austria unless he had Italy with him, and nothing from Italy without the evacuation of Rome. Even after the war with Prussia had actually broken out he refused Italian aid at the price of the abandonment of the city, a step which he nevertheless reversed hurriedly twenty days too late. With Napoleon fell the temporal power; but the French hierarchy still kept his gifts in the shape of the congregations, the pro-Catholic colonial policy, and a certain control of education. Of these privileges the Church was to be deprived a generation later. The Third Republic can never forget that it was to the support of the temporal sovereignty of the pope that Napoleon III. owed his empire and France her deepest humiliation.

On the withdrawal of the French garrison Rome was occupied by the troops of Victor Emmanuel. This monarch had always been a thorn in the side of the papacy. Under him Sardinia had adopted the Siccardi Laws of 1850, which had taken away the right of asylum and the jurisdiction of the Church over its clergy. His reputation for sacrilege, increased five years later by the abolition of many monasteries, became notorious when the formation of the kingdom of Italy (1861) took away all the dominions of the pope except the patrimony of Peter, thereby reducing the papal provinces from twenty to five, and their population from over 3,000,000 to about 685,000. This act was followed in 1867 by the confiscation of church property, and on the 20th of September 1870 by the triumphant seizure of Rome.

If France was the right arm and Italy the scourge of the papacy under Pius IX., the Spanish-speaking countries were its obedient tools. Torn by civil wars, their harassed rulers sought papal recognition at a cost which more experienced governments would have refused.

Thus Isabella II. of Spain in the concordat of 1851 confirmed the exclusive privileges of the Roman religion and gave the control of all education to the Church; but after the Revolution of 1868 Spain departed for the first time from the principle of the unity of the faith by establishing liberty of worship, which was, however, a dead letter. On the Spanish model concordats were arranged with various Central and South American republics, perhaps the most ironclad being that concluded with Ecuador in 1862 (abrogated 1878).

Among the more stable governments of Europe reaction in favour of conservatism and religion after 1848 was used by clerical parties to obtain concordats more systematic and thoroughgoing than had been concluded even after 1814. Austria, for instance, although long the political mainstay of the papacy, had never abandoned the broad lines of ecclesiastical policy laid down by Joseph II.; but the young Francis Joseph, seeking the aid of Rome in curbing heterogeneous nationalities, in 1855 negotiated a concordat whose paragraphs regarding the censorship, education and marriage were far-reaching. It was, moreover, the first document of the sort in which a first-class power recognized that the right of the Church to establish "divine institution and canon law," not upon governmental concession. Violated by the Liberal constitution of 1867, which granted religious liberty, depotentiated by laws setting up lay jurisdiction over matrimonial cases and state control of education, it was abrogated in 1870 by Austria, who alleged that the proclamation of papal infallibility had so altered the status of one of the contracting parties that the agreement was void.

Passing over Portugal, the remaining European state which is Roman Catholic is Belgium. Torn from Austria by the clerical revolution of 1790, after many vicissitudes it was united in 1815 with Holland and placed under the rule of the Protestant William I., king of the United Netherlands. The constitutional guarantee of religious liberty had from the outset been resisted by the powerful and restless priesthood, supported by numerous sympathizers among the nobility. As the arbitrary king alienated the Liberal Catholics, who were still more or less under the spell of the French Revolution, the Catholic provinces took advantage of the upheavals of 1830 to form the independent kingdom of Belgium. Its Fundamental Law of 1831, conceived in the spirit of the English Whigs, and later imitated in the European countries, granted liberty of worship and of education. Strangely enough, this liberty meant increase of power for the Clericals; for besides putting an end to stringent state interference in the education of future priests, it made possible a free and far-reaching Catholic school system whose crown was the episcopally controlled university of Louvain (1834). The Education Act of 1842 led to the formation of the Liberal party, whose bond of union was resistance to clericalism, whose watchword was the "independence of the civil power." The Catholics and Liberals were alternately in control until 1894, when the tenfold enlargement of the electorate broke down the Liberal party completely. The chief theme of contention, developed through many a noteworthy phase, has been the question of schools. In the half-century from 1850 to 1880 the cloisters likewise prospered and multiplied fivefold. The result of this evolution is that Belgium is to-day the most staunchly Catholic land north of the Alps.

In Holland, as in Belgium, the education question has been uppermost. Here, even after 1831 the Roman Catholics constituted three-eighths of the population. Allied with the Liberals against the orthodox Protestants, who were threatening religious liberty, the Catholics assisted in 1857 to establish a system of non-sectarian state schools, where attendance is not obligatory nor instruction gratis. Changing front, in 1868, in league with the orthodox, they tried to make these denominational; but as the Liberals defeated their attempt, they founded schools of their own.

In the non-Catholic countries of Europe during the reign of Pius IX. and in fact during the whole 19th century, the important gains of Rome were in strategic position rather than in numbers. The spread of toleration, which always favours minorities, broke down between 1845 and 1875 the Lutheran exclusiveness of Norway, Denmark and Sweden; but as yet the Catholics form a disappearing fraction of the population. In European Russia, as a result of the partitions of Poland under Catherine II. (1762-1766), about one-tenth of the people are Roman Catholics. The Ruthenians had united with Rome at Brest in 1596, forming a group of Uniates distinct from the Poles, who belonged to the Latin rite. In spite of the assurances of Catherina, Russia has repeatedly persecuted the Russian Uniates, in order to incorporate them into the Holy Orthodox Church; and she has occasionally taken drastic measures against the Poles, particularly after the revolts of 1830 and 1863. After more than a century of repression in 1903 the Edict of Toleration brought some relief.

The remarkable extension of the Catholic hierarchy by Pius IX. into Protestant lands, legally possible because of toleration, was in some cases made practicable because of immigration. Though this factor was perhaps not prominent in the case of Holland (1853) or Scotland (1878) it was Irish immigration which made it feasible in England (1850). For a time the Roman Catholic propaganda in England, which drew to itself High Churchmen like Newman and Manning, was viewed with apprehension; but though the Roman Catholic Church has grown greatly in influence in the country, the number of its adherents, in proportion to the growth of population, has not very greatly increased.

In the United States of America, however, the Catholic population has increased by leaps and bounds through immigration. The fames of the "forties, with their subsequent political and economic difficulties, transferred to America millions of the Irish, whose genius for organization in politics has not fallen short of their zeal for religion. The German-speaking immigrants have also had a creditable share in the work of church extension; but the Italians have manifested no marked ardour for their faith. The losses in transplantation have been huge, but it is impossible to estimate them accurately, for even the
current figures for the Catholic population are based on detailed estimates rather than on an actual count.

Summing up the history of the papacy from the Congress of Vienna to the fall of the temporal power, one finds statistical gains in Protestant countries offset perhaps by relative losses in Catholic lands, both largely due to the closely related forces of toleration and immigration. While the hold of the popes on the States of the Church was constantly weakening, their power over the domestic policies of foreign governments was increasing; and the transition from absolutism to parliamentary rule accelerated this process, at least in non-Catholic territories. The unparalleled spread of ultramontane ideas (see ULTRAMONTANISM) brought about a centralization of authority at Rome such as would have appalled the 18th century. This centralization was, however, for the time still not so much legal as doctrinal. In 1854 Pius IX. by his sole authority established a dogma (see IMMACULATE CONCEPTION); and the infallibility implied in this act was openly acknowledged in 1870 by the Council of the Vatican (see VATICAN COUNCIL and INFALLIBILITY). Thus were the spiritual prerogatives of the papacy exalted in the very summer that the temporal power was brought low.

(W. W. R.*

V.—Period from 1870 to 1900.

The few months that elapsed between the 18th of July 1870 and the 18th of January 1871 witnessed four events that have been fraught with more consequence to the papacy than anything else that had affected that institution for the past three centuries. They were as follows: (1) The proclamation of the Infallibility of the Pope on the 18th of July 1870; (2) the fall of the Napoleonic empire and the establishment of the third French republic on the 4th of September 1870; (3) the occupation of Rome by the Italian forces on the 20th of September 1870, resulting in the incorporation of the remaining states of the Church in the kingdom of Italy; and (4) the foundation of the German Empire by the proclamation on the 18th of January 1871, of the king of Prussia as hereditary German emperor. These changes, which so greatly disturbed the current of all European relations, could not fail to react upon the papal policy in various ways. They brought its existing tendencies into greater relief, set before it new aims and diverted it into new channels. Essential modifications could not, of course, be at once effected or even indicated in a power whose life-blood is tradition, and whose main strength has always lain in calmly abiding the issue of events and in temporizing. The eight years that Pius IX. was permitted to see after the loss of his temporalities entirely harmonize with this character. The veil that hides the negotiations which, during the closing months of the Franco-German War, were carried on between Bismarck and the pope, through the agency of Cardinal Bonhöte, has not yet been lifted, and perhaps never will be. According to Prince Bismarck's own account of the matter given in his Gedanken und Erinnerungen, these negotiations were initiated by the chancellor, who, between the 5th and 9th of November 1870, entertained pourparlers with Archbishop Ledochowski on the question of the territorial interests of the pope. The chancellor, acting, as he himself says, in the spirit of the adage, “one hand washes the other,” proposed to that prelate that the pope should give earnest of the relations subsisting between him and Germany by influencing the French clergy in the direction of the conclusion of peace. The cool reception his endeavours met with, both at the hands of the French ecclesiastics as well as in Rome, satisfied Bismarck that the papal hierarchy lacked either the power or the good will to afford Germany assistance of sufficient value to make it worth while giving umbrage to both the German Protestants and the Italian national party, and risking the opinion of the latter upon the future relations between the two countries, which would be the inevitable result were Germany openly to espouse the papal cause in Rome. These utterances are eminently characteristic. They show how far Bismarck was (even at the close of 1870) from comprehending the traditional policy of the papacy towards Germany and German interests, and how little he conceived it possible to employ the relations between the future empire and the Vatican as a point of departure for a successful and consistent ecclesiastical policy. Rome, in a certain sense, showed itself possessed of far greater foresight. The German politicians and the Prussian diplomats accredited to Rome had worked too openly at undermining the papal hierarchy, and had veiled their sympathies for Piedmont far too lightly to lead the Vatican to expect, after the 20th of September 1870, a genuine and firm intervention on the part of Prussia on behalf of the temporal power of the Holy See. To satisfy the demands of Bismarck in November 1870 would have cost the Vatican more than it would ever have gained. It could neither afford to trifle with the sympathies of the French Catholics nor to interrupt the progress of those elements, which would naturally be a thorn in the side of the young German Empire, thus undo Bismarck's work, and restore the Vatican policy to its pristine strength and vigour. It was soon to be perceived how carefully the Curia had made its calculations.

The address of the Catholic deputies to the emperor William in Versailles on the 18th of February 1871, pleading for the restoration of the States of the Church and the temporal sovereignty of the pope, and for the reconstitution of the Catholic group formed in the Prussian Landtag in 1860 as the CENTRUM or Centre Party in the new Reichstag (April 1871), must not be regarded as the origin but rather the immediate occasion of the Kulturkampf. The congratulations which the pope sent to the emperor William on receiving the announcement of the establishment of the German Empire (March 6, 1871) were a last exchange of civilities, and the abolition of the Catholic department in the Prussian ministry of public worship (July 8, 1871) quickly followed, together with the appointment of Falk as Kulturminister (Jan. 22, 1872), and the School Inspection Law of 1872 of Prussia, or the Centrum of Bismarck.

On the 30th of January Bismarck took the opportunity of inveighing against the formation of the sectarian Centrum as being “one of the most monstrous phenomena in the world of politics,” and he left no room for doubt in the minds of his hearers that he regarded the leadership of Windthorst as constituting, in his eyes, a peril to the national unity. In his Memoirs (ii. 126) he declares that the Kulturkampf was mainly initiated by him as a Polish question. This declaration, in view of the development of affairs, must appear as strange as the chancellor's confession (Memoirs, ii. 129 seq.) that he endeavoured to persuade the emperor of the advantage of having a nuncio accredited to Berlin (in lieu of the Catholic department of public worship). The refusal of the emperor William to entertain this project shows that in such matters his judgment was more correct than that of his councillor, and the incident proves that the latter had misjudged but a clear insight into the historical position. He was drifting about with no higher aim than a “hand-to-mouth” policy, whilst the Holy See could feel the superiority with which the consciousness of centuries of tradition had endowed it, and took full advantage of the mistakes of its opponent. The chancellor never realized the gravity of the onslaught which, with his Kulturkampf, he was making upon the conscience and liberty of his Catholic fellow citizens. He dealt with the great question at issue from the standpoint of the diplomatist, rather than from that of the statesman well versed in ecclesiastical history and possessing an insight into what it implies; and by his violent, inconsiderate action he unwittingly drove into the ranks of Ultramontanism the moderate elements of the Catholic population. This conflict, moreover, brought Ultramontanism the enormous advantage that, even after the abolition of the May Laws, it had still left to it a well-disciplined press, an efficient organization, and a network of interests and interested parties; and all these combined to make the Centrum the strongest and the most influential political party in Germany for the remainder of the 19th century. Owing to these circumstances, the rise and further development of the
Kulturkampf were viewed in Jesuit and Vatican circles with feelings of the utmost complacency. The very ecclesiastical policy of Pius IX. was guided by the earnest desire to see the doctrine of Papal Infallibility brought to universal recognition. The definition of the Immaculate Conception (1854) and the proclamation of the Syllabus (1864) were finger-posts pointing the way to the Council of 1870. The pope had been persuaded that the proclamation of the new dogma would be effected without difficulty and without discussion; and when the pronouncement actually met with opposition, he was both surprised and embittered. For a moment the idea was entertained of giving way to the opposition and deferring a decision in the matter, or, in the manner of the fathers in the Council of Trent, adjourning it to the Greek kalends. But the party that needed for its purposes an infallible pope readily persuaded Pius IX. that if the council broke up without arriving at a decision favourable to the papacy, this would be tantamount to a serious defeat of the Holy See and an open victory for the Gallican system. The consequence was the bull Pascendi, which Pius IX. issued on the 15th of July. This did not offer to satisfy all the demands of the Jesuits, and it was couched in terms which appeared not unacceptable to the majority of the Catholics. The fact that the bishops were prepared to forego their opposition was not unknown in Rome. It was anticipated by the authorities. But in Germany, as also in France, the waves of anti-Infallibility were rolling so high, that the further development of events was viewed with no small concern. Under normal conditions, the situation could not fail to terminate favourably for the Vatican. That the Kulturkampf had followed so rapidly upon the war was the greatest piece of good fortune that could have befallen the Holy See. The war demanded both in Germany and France the sacrifice of all available energy and public spirit; while the Kulturkampf, by bringing into relief the question of the external existence of the Church, thrust all internal dogmatic interests and problems completely into the background. The egregious blunder in the May Laws was the punitive clauses directed against the inferior clergy. Instead of enlisting them as friends, the Prussian government contrived by wild and wanton persecution to make them its enemies. The open protection it accorded to the Old Catholic movement contributed in no small measure to estrange those influential elements which, whilst favouring the suppression of Ultramontane tendencies, desired no schism in the Church, and viewed with horror the idea of a National Church in Bismarck's sense (see Old Catholics). Thus we find that the bitter years of the Kulturkampf extricated the Vatican from one of the most difficult situations in which it had ever been placed. Pius IX. could now fold his hands, so far as the future was concerned. It is well known that he fed on inspirations, and expected each day the advent of some supernatural occurrence which should bring about the triumph of the Church. In this frame of mind, on the 24th of June 1873, he addressed the German Leserrein, and referred to the stone that would some day fall from on high with the force of the Colossus. Yet the stone has not fallen from the summit of the holy hill, and the Colossus of the German Empire has not crumbled into dust, which is more than can be said for the pope's inspirations, which led him to expect the sudden withdrawal of the Italians from Rome, and a solution of the Roman question in the sense inspired by his visionary policy. The Holy See directed all its energies towards the solution of the problem; in the event of its proving to be insoluble, it would take care that it should remain a festering sore in the body of the monarchy. (For the Kulturkampf see further Germany: History.)

The documents of the Vatican Council which have been published since 1870 leave no room for doubt that the proclamation of Papal Infallibility was intended to be followed by a further declaration, to the effect that the doctrine of the temporal power of the pope should be regarded as a revealed article of faith; yet the advantage and necessity of the temporal power were not to be regarded as a revealed dogma properly speaking, but as a truth guaranteed by the doctrinal body of the Holy Church. These articles, contained in the 5th Scheme, and zealously championed by the sectaries of the Jesuit order, reveal the immediate object for which the council of 1870 was convened. The resolutions were devised to save the situation, in view of the impending loss of the temporalities. No one could expect that Pius IX. would recognize the annexation of Rome by Italy. Rome, even in the 19th century, had been a spectator of many changes in the political world. It had seen more than one kingdom rise and fall. No wonder, then, that the Vatican, confronted by a new Italy, observed a passive and expectant attitude, and sanctioned no positive and the new jot or title that could infringe its rights or be interpreted as a renunciation of its temporal sovereignty. It was just in keeping that Pius IX. availed himself to the full of the (for him) convenient clauses of the Italian Law of Guarantees (May 13, 1871), while refusing the civil list of three and a quarter million lire provided for his use, and inhibiting Italian Catholics from participating in the elections to the House of Deputies (né électo né élu). This step was regarded in Italy as a natural one. Although the Liberal record of the pope was a thing of the past, the party that had, since Gaeta, become firmly identified with the reactionary policy of Antonnelli, yet the early years of his pontificate were in such lively recollection as to allow of Pius IX.'s appearing to some extent in the light of a national hero. And rightly; for he had always had a warm heart for Italy; and had it not been for the anti-ecclesiastical policy of the house of Piedmont, he would not, in the sixties, have been wholly averse from reconciliation. The hitherto unpublished correspondence of the pope with Victor Emmanuel contains remarkable proofs in support of this contention, and a further corroborating act can also be perceived in the conciliatory attitude of Pius IX. on the death of the king.

Pius died on the 7th of February 1878, only a few weeks later than his opponent. He had long passed the traditional years of Peter's pontificate, had reigned longer than any previous wearer of the tiara, and had seen some brilliant days—days of illusive glory. On his death he left the Church shaken to its very foundations, and in feud with almost every government. In Italy the Holy See was surrounded by a hostile force, whose "prisoner" the lord of the Vatican declared himself to be. In Spain and Portugal, and also in Belgium, a Liberalism inimical to the Church was in power. Prussia, together with other German states, was in arms against pope and episcopate. In France the Conservative Monarchical party had just shown its inability to preserve the Crown, whilst the Republic had anchored itself firmly by denouncing the clergy as its enemy. There was hardly a sovereign or a government in Christendom against which Pius IX. had not either protested or attacked which he had not openly declared war. Such was the heritage that devolved upon Leo XIII. on his election on the 20th of February 1878.

Leo XIII. brought to his new dignity many qualities that caused his election to be sympathetically received. In contrast with his predecessor, he was a man of slow and calm deliberation, and it was said that the life of his pontificate was little, if at all, accessible to impulses of the moment or to the persuasions of his entourage. He was endowed with a certain scholastic erudition, and enjoyed the reputation of being a good Latinist. As nuncio in Brussels he had become acquainted with the trans-Alpine world, and had been initiated into the working of the machinery of modern politics and modern parliamentary government. The fact that he had for so long been absent from Rome afforded ground for the belief that he was not inclined to identify himself with any of the parties at the Vatican court. These were the considerations that had caused the Law of Guarantees the pope was recognized as an independent sovereign, with jurisdiction over his own palaces and their extensive precincts and the right to receive diplomatic representatives accredited to him. He also received the right to appoint bishops, who—except in Rome and the suburban district were to be Italian subjects; and, with a significant exception, the exequatur, placit regium, and every form of government permission for the publication and execution of acts of ecclesiastical authority were abolished. (See also Italy: History.)
the Moderates in the Sacred College to fix their eyes upon him. The appointment of Franchi as secretary of state was a bid for peace that was viewed by the Irreconcilables with ill-disguised vexation. The following years of Leo XIII's pontificate only tended to increase their dissatisfaction. The first care of the new pope was to pave the way for the restoration of peace with Russia and the German Empire, and it was owing to his patience, persistence and energy that these efforts for peace were crowned with success. In the case of Germany he made many concessions which appeared to the Zelanti to be excessive, and made even still greater ones to France and Russia, to the great distress of the Pole. But at last Leo XIII. could boast not only of having re-established diplomatic relations with most of the powers, but also of having entered into a convention with the great powers of the North, which accorded him, in conjunction with the three emperors, a leading position as champion of the conservative interests of humanity. How proud Leo XIII. was of his importance in this position is shown by the beautiful encyclical, De civilitate constitutione christiana ("Immortale Dei" of Nov. 1, 1889), in which he adopted the strongest attitude against the principle of the sovereignty of the people (ex istis autem Pontificum praebentibus illud omnino intelligent esse et, potius, potestas capitale esse, non Deo ipso, non a moribus, sed ex eo, quod publica potestate non esse nisi populi voluntatem, and absolutely rejecting the sovereignty of the people as such. But this attitude was adopted by Leo XIII. not as an end but as a means. The real aims of his rule were disclosed in the second phase of his pontificate.

At its very commencement, the pope in his first encyclical (1878) proclaimed the necessity of a temporal hierarchy. This was at the time regarded merely as a formality imposed by circumstances, and one not to be seriously entertained; but it became more and more evident that the recovery of the temporalities was the real mainspring of Leo's whole policy. In the negotiations with Germany, it was clearly seen that it was from that side that the pope expected intervention in favour of restitution; and, according to all appearances, Bismarck did for a while keep alive these representations, though with more tact than candour. After peace had been concluded, Leo, by the agency of Galimberti, reminded the chancellor of the settlement of the Roman question. Bismarck replied that he was "unaware of the existence of any such question." The two visits paid by Emperor William II. to the Vatican could not fail to remove any doubts in the mind of the pope as to the fact that Germany did not dream of giving him back Rome. The Austro-German-Italian triple alliance was a dire blow to his expectations, and Crispi's policy with its irritating and galling pin-pricks caused the cup to overflow.

Thus slowly, but yet deliberately, between 1887 and 1893, a transformation took place in Leo's spirit and policy, and with Leo XIII. and the French Republic it was brought about one of the most momentous changes in the attitude of the Church towards the problems of the times and their impelling forces. A rapprochement with France inevitably entailed not only an alliance with modern democracy, but also a recognition of its principles and aims. In Rome there was no room for both pope and king. The note of the pope to Rampolla of the 8th of October 1893, in consequence of the celebrations on the 20th of September, declared, in terms more decided than any that had until then been uttered, that the papacy required a territorial sovereignty in order to ensure its full independence, and that it was therefore willing to negotiate the cession of the kingdom of Italy as then constituted. The inevitable consequences ensued. Italy regarded the pope more than ever as a foe within its walls; and the policy of the pope, as regards Italy, aimed at replacing the kingdom by one or more republics, in which the temporal power should, in some form or other, find a place. But the continuance of the Republic in Paris was a condition precedent to the establishment of a republic in Rome, and the first had no chance of existence if the democracy in France did not remain in power. The result was the policy of the Ralliement. Instructions were given to the French Catholics to break with monarchial principles, and both externally and internally to cleave to the Republic as representing the best form of constitutional government. In carrying out the régime of Rampolla, which was, in every respect, a bad imitation of that of Antonelli, the Vatican left no stone unturned in its attempt to coerce the conscience of the French royalists; it did not even stop at dis-honour, as was evidenced by the case of the unhappy Mgr d'Hulst, who, in order to evade the censorship of his pamphlet on Old Testament criticism, had to abandon both his king and his principles, only to die in exile of a broken heart. The case was characteristic of the whole Catholic monarchical party, which, owing to the pope's interference in French politics, became dis-integrated and dissolved, a fate that was all the more painful seeing that the Ralliement failed to influence the course of events. The "atheistic" Republic did not for one moment think of putting on sackcloth, or even of giving the Church a single proof of esteem and sympathy.

In one respect it was impossible for the papacy to continue on the path it had taken. In his first encyclical, Leo XIII. had sounded the clarion for battle against the Social Democratic party, his encyclical being an attempt to deavour to show the means to be employed, mainly in view of the condition of things in Belgium, for solving the social question on Christian lines. But the Christian Democracy, which, starting in Belgium and France, had now extended its activity to Italy, Austria and Germany, and was striving to arrive at this solution, degenerated everywhere into a political party. The leaders of this party came into close contact with the Social Democrats, and their relations became so cordial that Social Democracy everywhere declared the "Démocratie Chrétienne" to be its forerunner and pioneer. The electioneering alliances, which were everywhere in vogue, but particularly in Germany, between the Catholics and popular party and the Social Democrats, threw a lurid light upon the character of a movement that certainly went far beyond the intentions of the pope, but which it was now difficult to undo or to hold in check. For it is the essence of the matter that there were further considerations going far beyond the Roman question and forcing the Curia to adhere to the sovereignty of the people.

The internal rehabilitation of the Church had become, in many points, a fait accompli, but, internally, events had not kept pace with it. Catholic romanticism had withered away in France, as it had in Germany: "Liberal Catholicism," which was its offspring, had died with Montalembert, after being placed under a ban by Rome. The national religious movement, associated in Italy with the great names of Rosmini and Gioberti, had similarly been disavowed and crushed. The development of the last decade of the 19th century had clearly shown that the educated bourgeoisie, the tiers état, in whose hands the supreme power had since 1848 become vested throughout Europe, was either entirely lost to the Church or, at all events, indifferent to what were called Ultramontane tendencies. The educated bourgeoisie, which controls the fields of politics, science, finance, administration, art and literature, does not trouble itself about that great spiritual universal monarchy which Rome, as heir of the Caesars, claimed for the Vatican, and to which the Curia of to-day still clings. This bourgeoisie and the modern state that it upholds stand and fall with the modern civil and political institutions of the day: the modern law, the modern system of municipal and spiritual liberty, institutions with which the ideas of the Curia are in direct conflict. The more the hope of being able to regain these middle classes of society disappeared, the more decidedly did the Curia perceive that it must seek the support and the regeneration of its power in the steadily growing democracy, and endeavour through the medium of universal suffrage to secure the influence which this new alliance was able to offer.

The pontificate of Leo XIII. in its first phase aimed at preserving a certain balance of power. Whilst not openly compelling...
The Papacy

The Papacy and the Modern Democracy

The Papacy

[1900-1910]

PAPACY

720

The Jesuits, Leo yet showed himself well disposed towards, and even amenable to, views of a diametri-

cally opposite kind; and as soon as the Vatican

threw itself into the arms of France, and bade fare-

well to the idea of a national Italy, the policy of

equilibrium had to be abandoned. The second phase

in Leo's policy could only be accomplished with the aid of

the Jesuits, or rather, it required the submission of the ecclesiastical

hierarchy to the mandates of the Society of Jesus. The

further consequence was that all aspirations were subjected to the

thraldom of the Church. The pontificate of Leo XIII. is

distinguished by the great number of persecutions, prosecutions

and injuries inflicted upon Catholic savants, from the prosecution

of Antonio Rosmini down to the proscription directed against

the heads of the American Church. Episodes, such as the

protection so long extended to the Leo Taxil affair, and to the

revelations of Diana Vaughan (the object of which last was to

bring Italian freemasonry and its ostensible work, the unity

of Italy, into discredit), together with the attitude of the Ultra-
montane press in the Dreyfus affair, and later towards England,

the invigoration of political agitation by the Lourdes celebration

and the publication of Pius IX.'s apostolic constitution, to

raise the "system" in the estimation of the cultured and civilized

world. Perhaps even more dangerous was the employment of

the whole ecclesiastical organization, and of Catholicism

generally, for political purposes.

No one will be so foolish or so unjust as to hold Leo XIII.

responsible for the excesses committed by the subordinate

departments of his government, in disclosing prosecuting

and sometimes even fraudulently misrepresenting his aims and ends.

But all these details, upon which it is not necessary to dwell,

are overshadowed beyond all doubt by the one great fact that

the ecclesiastical régime had not only taken under its wing

the solution of social questions, but also claimed that political

action was within the proper scope of the Church, and, moreover,

arrogated to itself the right of interfering by means of "Direc-

tives" with the political life of nations. This was nothing new,

for as early as 1215 the English barons protested against it.

But the weakening of the papacy had allowed this claim to

lapse for centuries. To have revived it, and to have carried it

out as far as is possible, was the work of Leo XIII.

It would be both presumptuous and premature to pass a final

verdict upon the value and success of a policy to which, whatever

else be said, must be accorded a certain meed of praise for its

daring. Even in 1892 Spiller, in his essay upon Lamennais,

pointed out how the latest evolution of Catholicism was taking

the course indicated by Lamennais in his Livre du peuple (1837),

and how the hermit of "La Chânaie," who departed this life

in bitter strife with Rome, declared himself to be the actual

precursor of modern Christian Socialism. He hinted that

the work of Leo XIII. was, in his eyes, merely a new attempt to

build up afresh the theocracy of the middle ages upon the ruins

of the old monarchies, utilizing to this end the inexperience of

the young and easily beguiled democracies of the dawning 20th

century. To comprehend these views aright, we must first

remember what in the first half of the 19th century, and also in the
days of Lamennais, was understood by Democracy was not coincident with the meaning of this expression as it was

afterwards used, and as the Christian Socialists understood it.

Down to 1846, and even still later, "Democracy" was used to

cover the whole mass of the people, pre-eminently represented

by the broad strata of the bourgeoisie; in 1900 the Democratic

darty itself meant by this term the rule of the lower class

organized as a nation, which, by its numerical superiority,

thrust aside all other classes, including the bourgeoisie, and

excluded them from participation in its rule. In like manner

it would be erroneous to confuse the sense of the expression as

it obtains on the continent of Europe with what is understood

under this term in England and America. In this latter

case the term "Democracy," as applied to the historical

development of Great Britain and the United States, denotes

a constitutional state in which every citizen has rights

proportionate to his energy and intelligence. The socialist

idea, with which the "Démocratie Chrétienne" had identified

itself both in France and Belgium, regards numbers as the

centre of gravity of the whole state organism. As a matter of

fact it recognizes as actual citizens only the labourer, or,

in other words, the proletariat.

On surveying the situation, certain weak points in the policy

of the Vatican under Leo XIII. were manifest even to a con-
temporary observer. They might be summed up as follows:

(1) An unmistakable decline of religious fervour in church life.

(2) The intensifying and nurturing of all the passions and

questionable practices which are so easily encouraged by practical

politics, and are incompatible in almost all points with the

priestly office.

(3) An ever-increasing displacement of all the

refined, educated and nobler elements of society by such as are

rude and uncultured, by what, in fact, may be styled the ecclesi-
asical "Trottori."

(4) The naturally resulting paralysis of intelligence and scientific research, which the Church either

proscribed or only sullenly tolerated.

(5) The increasing decay and waxing corruption of the Roman nations, and the fostering of the
decedent state of things which displayed itself in France

by the Dreyfus and the Dreyfus affair, in Germany by the

Dreyfus movement, and the campaign for and against the Assumptionists

and their newspaper, the Croix. (6) The increasing estrange-

ment of German and Anglo-Saxon feeling. As against these,

noteworthy reasons might be urged in favour of the new

development. It might well be maintained that the faults just

enumerated were only cankers inseparable from every new

great movement, and that these excrescences would disappear in

course of time, and the whole movement enter upon a more

tranquil path. Moreover, in the industrial districts of Germany,

for example, the Christian industrial movement, supported by

Protestants and Catholics alike, had achieved considerable

results, and proved a serviceable means of combating the

seductions of Socialism. Finally, the Church had reminded the

wealthy classes of their duties to the sick and toilers, and by

making the social question itself it had gone a long way

towards permeating all social and political conditions with the

spirit of Christianity.

VI. — Period from 1900 to 1910.

On the 3rd of March 1903 Leo XIII. celebrated his Jubilee

with more than ordinary splendour, the occasion bringing him

rich tributes of respect from all parts of the world, Catholic

and non-Catholic; on the 20th of July following he died. The

succession was expected to fall to Leo's secretary of state,

Cardinal Rampolla; but he was credited with having inspired

the French sympathies of the late pope; Austria exercised its right of

veto (see Conclave, ad fin.), and on the 8th of August, Giuseppe

Sarto, who as cardinal patriarch of Venice had shown a friendly

disposition towards the Italian government, was elected pope.

He took as his secretary of state Cardinal Raphael

Plus X

Merry del Val, a Spaniard of English birth and educa-

tion, well versed in diplomacy, but of well-known ultramontane

tendencies. The new pope was known to be no politician, but

a simple and saintly priest, and in some quarters there were

hopes that the attitude of the papacy towards the Italian kingdom

might now be changed. But the name assumed, Plus X.,

was significant; and, even had he had the will, it was soon
clear that he had not the power to make any material departure from

the policy of the first "prisoner of the Vatican." What was

even more important, the new régime at the Vatican soon made

itself felt in the relations of the Holy See with the world of

modern thought and with the modern conception of the state.

The new pope's motto, it is said, was "to establish all things

in Christ" (instaurare omnia in Christo); and since, ex hypothesi,

he himself was Christ's vicar on earth, the working out of this

principle meant in effect the extension and consolidation of the

papal authority and, as far as possible, an end to the com-

promises by means of which the-papacy had sought to make

friends of the Mammon of unrighteousness. It was this spirit

which informed such decrees as that on "mixed marriages"
(Ne temere) of 1907, which widened still further the social gulf between Catholics and Protestants (see Marriage: Canon Law), or the refusal to allow the French bishops to accept the Associations Law passed by the French government after the denunciation of the concordat and the separation of Church and State (see France: History): better that the Church in France should sink into more than apostolic poverty than that a tithe of the rights of the Holy See should be surrendered. Above all it was this spirit that breathed through every line of the famous encyclical, Pascendi gregis, directed against the "Modernists" (see Roman Catholic Church: History), which denounced with bitter scorn and irony those so-called Catholics who dared to attempt to reconcile the doctrine of the Church with the results of modern science, and who, presumptuously disregarding the authority of the Holy See, maintained "the absurd doctrine that would make of the laity the factor of progress in the Church."

That under Pius X. the papacy had abandoned none of its pretensions to dominate consciences, not of Catholics only, was again proved in 1910 when, at the very moment when the pope was raising the English people for the spirit of tolerance which led the British government to introduce a bill to alter the form of the Declaration made by the sovereign on his succession to the crown, and which form of acceptance the pope was renouncing without the government of Spain for arrogating the law forbidding the Spanish dissident churches to display publicly the symbols of the Christian faith or to conduct their services otherwise than semi-privately.

In pursuance of the task of strengthening the Holy See, the Vatican policy under Pius X. was not merely one of defiance towards supposed hostile forces within and without the Church; it was also strenuous in pushing on the work of internal organization and reform. In 1904 a commission of cardinals was appointed to undertake the stupendous task of codifying the canon law (see Canon Law), and in 1908 an extensive reorganization of the Curia was carried out, in order to conform its machinery more nearly to present-day needs (see Curia Romana).

In taking England, the United States and other non-Catholic states from under the care of the Congregation of the Propaganda, the pope raised the status of the Roman Catholic Church in those countries. All this changed ten years later, when the centennial of Pius IX's death, which marked the papacy's 20th century, coincided with the centenary of the death of the pope. Other reforms were of a different character. One of the earliest acts of the new pontificate was to forbid the use in the services of the Church of any music later than Palestrina, a drastic order justified by the extreme degradation into which church music had fallen in Italy, but in general honoured rather in the spirit than in the letter. More important was the appointment in 1907 of a commission, under the presidency of Abbot Gasquet, to attempt the restoration of the pure text of the Vulgate as St Jerome wrote it.

Such activities might well be taken as proof that the papacy at the outset of the 20th century possessed a vigour which it was far from possessing a hundred years earlier. Under Pius VI. and Pius VII. the papacy had reached the lowest depths of spiritual and political impotence since the Reformation, and the belief was even widespread that the prisoner of Fontainebleau would be the last of the long line of St Peter's successors. This weakness was due not to attacks from without—for orthodox Protestantism had long since lost its aggressive force—but to disruptive tendencies within the Church; the Enlightenment of the 18th century had sapped the foundations of the faith among the world of intellect and fashion; the development of Gallicanism and Febronianism threatened to leave the Holy See but a shadowy pre-eminence over a series of national churches, and even to obliterate the frontier line between Catholicism and Protestantism. It was the Revolution, which at one moment seemed finally to have engulfed the papacy, which in fact preserved it; Febronianism, as a force to be seriously reckoned with, perished in the downfall of the ecclesiastical principalities of the old Empire; Gallicanism perished with the constitutional Church in France, and its principles fell into discrediting with a generation which associated it with the Revolution and its excesses. In the reaction that followed the chaos of the revolutionary epoch men turned to the papacy as alone giving a foothold of authority in a confused and quaking world. The Romantic movement helped, with its idealization of a past but vaguely realized and imperfectly understood, and Chateaubriand heralded in the Catholic reaction with his Génie du Christianisme (1801) a brilliant if superficial attack on the encyclopaedists and their neo-Paganism, and a glorification of the Christian Church as supreme not only in the regions of faith and morals, but also in those of intellect and art. More weighty was the Du Pois of Joseph de Maistre (1810), closely reasoned and fortified with a wealth of learning, which had an enormous influence upon all those who thought that they saw in the union of the "altar and throne" the palladium of society. The Holy Empire was dead, in spite of the pope's protest at Vienna against the failure to restore the "centre of political unity"; Joseph de Maistre's idea was to set up the Holy See in its place. To many minds the papacy thus came to represent a unifying principle, as opposed to the disruptive tendencies of Liberalism and Nationalism, and the papal monarchy came to be surmounted with a new halo, as in some sort realizing that ideal of the "federation of the world" after which the age was dimly feeling.

So far as politics are concerned this sentiment was practically confined to certain classes, which saw their traditional advantages threatened by the revolutionary tendencies of the Prussian and modern times; and the alliance between the throne and the papal altar, by confusing the interests of the papacy with those of political parties, tended—as Leo XIII. had the wit to realize—to involve the fate of the one with that of the other, as in France. Far stronger was the appeal made by the authoritative attitude of the papacy to all those who were disturbed by the scientific spirit of the age: the ceaseless questioning of all the foundations on which faith and morality had been supposed to rest. Biblical criticism, by throwing doubt on the infallibility of the Scriptures, was undermining the traditional foundation of orthodox Protestantism, and most of the Protestant Churches, divided between antagonistic tendencies, were ceasing to speak with a certain voice. To logical but timid minds, like that of J. H. Newman, the pope might seem a compromise between truth, but fearing to face the realities of the rigidly authoritative attitude of Rome made an irresistible appeal. The process, maybe, from the point of view of those outside, was to make a mental wilderness and call it peace; but from the papal point of view it had a double advantage: it attracted those in search of religious certainty, it facilitated the maintenance of its hold over the Catholic democracy. The methods by which it has sought to maintain this hold are criticized in the article Ultramontanism.

There can also be little doubt—that the Curia itself would not admit it—that the spiritual power of the papacy has been greatly increased by the loss of the temporal power. The pope is no longer a petty Italian prince who, in order to preserve his dominions, was necessarily involved in the tangle of European diplomacy; he is the monarch of a vast, admirably organized, spiritual world-empire, and when—"as must needs happen"—the overlapping of the spiritual and temporal spheres brings him into conflict with a secular power, his diplomacy is hacked, whatever Catholic sentiment is strong, by a force which the secular power has much difficulty in resisting; for in spiritual matters (and the term covers a wide field) the Catholic, however loyal to his country he may be, must obey God, whose viceroy is the pope, rather than man. Even Bismarck, in the end, had to "go to Canossa."

It is, indeed, possible to exaggerate this power. The fact that the Vatican presents a great force hostile to and obstructive of certain characteristic tendencies of modern life and thought has necessarily raised up a powerful opposition even in countries traditionally Catholic. France no longer desires the title of eldest daughter of the Church; the Catholicism of Italy is largely superficial; even Spain has shown signs of restiveness. On the
other hand, the great opportunity now open to the papacy on
its spiritual side, is proved by the growing respect in which it
has been held since 1870 in the English-speaking countries,
where Roman Catholics are in a minority and their Church is
in a process of establishment. Without doubt, opinion has been
influenced in these countries by the fact that Rome has not been
sufficiently strong to exercise any disturbing influence on the
general course of national affairs, while in both its conspicuous
members set a high example of private and civic conduct.

PAPER (Fr. papiere, from Lat. papyrus), the general name for the substance commonly used for writing upon, or for wrapping things in. The origin and early history of paper as a writing material are involved in much obscurity. The art of making it from fibrous matter appears to have been practised by the Chinese at a very distant period. Different writers have traced it back to the 2nd century B.C. But, however remote its age may have been in eastern Asia, paper first became available for the rest of the world in the middle of the 8th century. In 751 the Chinese occupied Samarkand early in the century, were attacked there by Chinese. The invasion was repelled by the Arab governor, who in the process was captured, and certain prisoners who were skilled in paper-making were brought back and imparted their knowledge to their new masters. Hence began the Arabian manufacture, which rapidly spread to all parts of the Arab dominions. The extent to which it was adopted for literary purposes is proved by the comparatively large number of early Arabic MSS. on paper which have been preserved dating from the 9th century.

There has existed a not inconsiderable difficulty in regard to the matter of which the Arab paper was composed. In Europe it has been referred to by old writers as charta bombycina, gossypina, cutine, xylina, damascena et serica. The last title seems to have been derived from its glossy and silken appearance; the title damascena merely points to its great central emporium, Damascus. But the other terms indicate an idea, which has been persistent, that the paper manufactured by the Arabs was composed of the wool from the cotton-plant, reduced to a pulp according to the method attributed to the Chinese; and it had been generally accepted that the distinction between Oriental paper and European paper lay in the fact that the former was of cotton-paper and the latter a rag-paper. But this theory has been based on distorted investigations, which have shown that the material of the Arab paper was more closely akin to linen.

It seems that the Arabs, and the skilled Persian workmen whom they employed, at once resorted to flax, which grows abundantly in Khorasan, as their principal material, afterwards also making use of rags, supplemented, as the demand grew, with any vegetable fibre that would serve; and that cotton, if used at all, was used very sparingly. Still there remain the old titles charta bombycina, &c., to be explained; and an ingenious solution has been offered that the term charta bombycina, or χάρμης βομβοκύα, is an erroneous reading of charta bombycina, or χάρμης βομβοκύα, paper manufactured at the Syrian town of Bambuce or βομβον, the Arab Mambidsch (Karabacek in Mittheilungen aus der Sammlung der Papyri Ehrlishiger Rainer, ii.–iii. (1897, iv. 117). Without accepting this as an altogether sufficient explanation of so widely used a term as the medieval charta bombycina, and passing from the question of material to other differences, paper of Oriental manufacture in the middle ages was usually distinguished by its stout substance and glossy surface, and was devoid of water-marks, the employment of which became universal in the Middle Ages. Before the titles referred to above, paper also received the names of charta and papirus, transferred to it from the Egyptian writing material manufactured from the papyrus plant (see Papyrus).

It was probably first brought into Greece through trade with Asia, and thence transmitted to neighbouring countries. Theophilus presbyter, writing in the 13th century (Schedula diver- sarum artium, i. 23), refers to it under the name of Greek parchment, pergamaena grecca. There is a record of the use of...
paper by the empress Irene at the end of the 11th or beginning of the 12th century, in her rules for the nuns of Constantinople. It does not appear, however, to have been very extensively used in Greece before the middle of the 13th century, for, with one doubtful exception, there are no extant Greek MSS. on paper which bear date prior to that period.

The manufacture of paper in Europe was first established by the Moors in Spain in the middle of the 12th century, the headquarters of the industry being Xativa, Valencia and Toledo. But on the fall of the Moorish power the manufacture, passing into the hands of the skilled Christians, declined in the quality of its production. In Italy also the art of paper-making was no doubt established through the Arab occupation of Sicily. But the paper which was made both there and in Spain, was in the first instance of the Oriental quality. In the laws of Alphonso of 1263 it is referred to as cloth parchment, a term which well describes its stout substance. The first mention of rag-paper occurs in the tract of Peter, abbot of Cluny (A.D. 1122-1150), adversus Judaeos, cap. 5, where, among the various kinds of books, he refers to such as are written on material made "ex rasuris veterum pannorum."

A few words may here be said respecting MSS. written in European countries on Oriental paper or paper made in the Oriental fashion. Several which have been quoted earlier in this book have proved to be made of nothing but vellum. The ancient fragments of the Gospel of St Mark, preserved at Venice, which were stated by Maffeii to be of paper, by Montfaucon of papyrus, and by the Benedictines of bark, are in fact written on skin. The oldest recorded document on paper was a deed of King Roger of Sicily, of the year 1102; and there are others of Sicilian kings, of the 12th century. A Visigothic paper MS. of the 12th century from Silos near Burgos is now in the Bibliothèque Nationale, Paris. A notarial register on paper, at Geneva, dates from 1154. The oldest known imperial deed on the same material is a charter of Frederick II. to the nuns of Goess in Styria, of the year 1228, now at Vienna. In 1231, however, the same emperor forbade further use of paper for public documents, which were in future to be inscribed on vellum. Transcripts of imperial acts of Frederick II. about A.D. 1241 are at Naples. In Venice the Liber plegiorum, the entries in which begin with the year 1293, is made of rough paper; and similarly the registers of the Council of Ten, beginning in 1325, and the register of the emperor Henry VII. (1308-1313) preserved at Turin, are also written on a like substance. In the British Museum there is an old example in a manuscript of 1568, which contains some astronomical treatises written on an excellent paper in an Italian hand of the first half of the 15th century. The autograph MS. of Albert de Baha, 1238-1255, at Munich, is on paper. In the Public Record Office there is a letter on paper from Raymond, son of Raymond, duke of Narbonne and count of Toulouse, to Henry III. of England, written within the years 1216-1222. The letters addressed from Castile to Edward I., in 1279 and following years (Paul in Bericht, Berl. Akad., 1854), are instances of Spanish-made paper; and other specimens in existence prove that in this latter country a rough kind of charta bombica was manufactured to a comparatively late date.

In Italy the first place which appears to have become a great centre of the paper-making industry was Fabriano in the marquisate of Ancona, where mills were first set up in 1276, and which rose into importance on the decline of the manufacture in Spain. The earliest known water-marks in paper from this factory are of the years 1293 and 1294. The jurat Bartolo, in his treatise De insignis et armis, refers to the excellent paper made at the middle of the 14th century, an encomium which will be supported by those who have had occasion to examine the extant MSS. on Italian paper of that period. In 1340 a factory was established at Padua; another arose later at Treviso; and others followed in the territories of Florence, Bologna, Parma, Milan, Venice and other districts. From the factories of northern Italy the wants of southern Germany were supplied as late as the 15th century. As an instance the case of Göritz has been cited, which drew its paper from Milan and Venice for the half century between 1376 and 1426. But in Germany also factories were rapidly founded. The earliest are said to have been set up between Cologne and Mainz, and in Mainz itself about 1320. At Nuremberg Ulman Strome established a mill in 1390, with the aid of Italian workmen. Other places of early manufacture were Ratisbon and Augsburg. Western Germany, as well as the Netherlands and England, is said to have obtained paper at first from France and Burgundy through the markets of Bruges, Antwerp and Cologne. France owed the establishment of her first paper-mills to Spain, whereas we are told the art of paper-making was introduced, as early as the year 1190, into the district of Hérault. At a later period, in 1406, among the accounts of the church of Troyes, paper-mills appear as molins à toile. The development of the trade in France must have been very rapid. And with the progress of manufacture in France that of the Netherlands also grew.

In the second half of the 14th century the use of paper for all literary purposes had become well established in all western Europe; and in the course of the 15th century it gradually superseded vellum. In MSS. of this latter period it is not unusual to find a mixture of vellum and paper, a vellum sheet forming the outer, or the outer and inner, leaves of a quire while the rest are made of paper. Some MSS. are entirely written on paper.

With regard to the early use of paper in England, there is evidence that at the beginning of the 14th century it was a not uncommon material, particularly for registers and accounts. Under the year 1310, the records of Merton College, Oxford, show that paper was purchased "pro registro," which Professor Rogers (Hist. Agricul. and Prices, i. 644) is of opinion was probably paper of the same character as that of the Bordeaux customs register in the Public Record Office, which date from the first year of Edward II. The college register referred to, which was probably used for entering the books that the fellows borrowed from the library, has perished. There is, however, in the British Museum a paper MS. (Add. 31, 223), written in England, of even earlier date than the one recorded in the Merton archives. This is a register of the husting court of Lyme Regis, the entries in which begin in the year 1309. The paper, of a rough manufacture, is similar to the kind which was used in Spain. It may have been imported direct from that country or from Bordeaux; and a seaport town on the south coast of England is exactly the place where such early relics might be looked for. Professor Rogers also mentions an early specimen of paper in the archives of Merton College, of which is written a bill in the year 1332, and some leaves of water-marked paper of 1333 exist in the Harleian collection. Only a few years later in date is the first of the registers of the King's Hall at Cambridge, a series of which, on paper, is preserved in the library of Trinity College. Of the middle of the 14th century also are many municipal books and records. The knowledge, however, which we have of the history of paper-making in England is extremely scanty. The first maker whose name is known is John Tate, who is said to have set up a mill in Hertford early in the 15th century; and Sir John Spelman, Queen Elizabeth's jeweller, erected a paper-mill at Dartford, and in 1589 obtained a licence for ten years to make all sorts of white writing-paper and to gather, for the purpose, all manner of linen rags, scrofis or parchments, old fishing nets, &c. (Dunkin, Hist. of Dartford, 305; Harl. MS. 2206, f. 124 b.) But it is incredible that no paper was made in the country before the time of the Tudors. The comparatively cheap rates at which it was sold in the 15th century in inland towns seem to afford ground for assuming that there was at that time a native industry in this commodity. As far as the prices have been observed at which different kinds of paper were sold in England, it has been found that in 1355-1356 the price of a quire of small folio paper was 3d., both in Oxford and London. In the 15th century the average price seems to have ranged from 3d. to 4d. for the quire, and from 3s. 4d. to 4s. for the ream. At the beginning of the 16th century the price fell to 2d. or 3d. the quire, and to 3s. or 3s. 6d. the ream; but in the second half of the century, owing to the debasement
PAPER

of the coinage, it rose, in common with all other commodities, to nearly 4d. the quire, and to rather more than 5s. the ream. The relatively higher price of the ream in this last part, as compared with that of the quire, seems to imply a more extensive use of the material which enabled the trader to dispose of bulk more quickly than formerly, and so to sell by the quire at a comparatively cheap rate.

Brown paper appears in entries of 1570–1571, and was sold in bundles at 2s. to 2s. 4d. Blotting paper is apparently of even earlier date, being mentioned under the year 1465. It was a coarse, grey, unsized paper, fragments of which have been found among the leaves of 15th-century accounts, where it had been left after being used for blotting. Early in the 16th century blotting-paper must have been in ordinary use, for it is referred to in W. Horman’s Vulgaria, 1510 (p. 80): “Blotting paper serveth to drye weete wryttyng, lest there be made blottis or blurris”; and early in the next century “charta bibula” is mentioned in the Pinacotheca (i. 175) of Niclus Erythraeus. It is remarkable that, in spite of the comparatively early date of this invention, sand continued generally in use, and even at the present day continues in several countries in fairly common use as an ink absorber. The use of various water-marks has yielded some results in tracing the different channels in which the paper trade of different countries flowed. Experience also of the different kinds of paper and a knowledge of the water-marks (the earliest of which is of about the year 1282) aid the student in fixing nearly exact periods of undated documents. European paper of the 14th century may generally be recognized by its firm texture, its stoutness, and the large size of its wires. The water-marks are usually simple in design; and, being the result of the impress of thick wires, they are therefore strongly marked. In the course of the 15th century the texture gradually becomes finer and the water-marks more elaborate. While the old subjects of the latter are still continued in use, they are more neatly outlined, and, particularly in Italian paper, they are frequently enclosed in circles. The practice of inserting the full name of the maker in the water-mark came into fashion early in the 16th century. But it is interesting to know that for a very brief period in the 14th century, from about 1307 to 1320, the practice actually obtained at Fabriano, but was then abandoned in favour of simpler water-marks, as is already apparent in the water-marks of the 13th century. The date of manufacture appears first in the water-marks of paper made in 1545. The variety of subjects of water-marks is most extensive. Animals, birds, fishes, heads, flowers, domestic and warlike implements, armorial bearings, &c., are found from the earliest times. Some of these, such as armorial bearings, and national, provincial or personal cognizances, as the imperial crown, the crossed keys or the cardinal’s hat, can be attributed to particular countries or districts; and the wide dissemination of the paper bearing these marks in different countries serves to prove how large and international was the paper trade in the 14th and 15th centuries.

PAPER MANUFACTURE

In the modern sense “paper” may best be described as a more or less thin tissue composed of any fibrous material, whose individual fibres, first separated by mechanical action, are then deposited and felted together on wire cloth while suspended in water (see Fig. 3). The main constituent in the structure of all plants is the fibre or cellulose which forms the casing or walls of the different cells; it is the woody portion of the plant freed from all foreign substances, and forms, to speak, the skeleton of vegetable fibre to the amount of 75 to 78%. Its forms and combinations are extremely varied, but it always consists of the same chemical elements, carbon, hydrogen and oxygen, and in the same proportions. It is the object of the paper-maker to eliminate the glutinous, resinous, siliceous and other intercellular matters and to produce the fibre as pure and as strong as possible. Linen and cotton rags, having already undergone a process of manufacture, consist of almost pure fibres with the addition of fatty and colouring matters which can be got rid of by simple boiling under a low pressure of steam with a weak alkaline solution; but the substitutes for rags, esparto, wood, straw, &c., being used as they come from the soil, contain all the intercellular matter in its original form, which has to be dissolved by strong chemical treatment under a high temperature. The vegetable fibre or cellulose, being of a tougher and stronger nature, is treated with the action of caustic soda (which is the chemical form of sodium), and at the same time the treatment has to be carried too far, whilst animal fibres or other organic matters are rendered soluble or destroyed by it. The cellulose, after its resolution by chemical treatment, is still impregnated with insoluble matters, which have to be eliminated or destroyed by treatment with a solution of chlorine or bleaching powder. The object of the paper-maker in treating any one particular fibre is to carry the action of the dissolving and bleaching agents just so far as to obtain the fibre as free from impurities and as white in colour as is desired. The usefulness of a plant for a good white paper depends upon the strength and elasticity of its fibres, upon the proportion of cellular tissue contained in them, and upon the ease with which this can be freed from the encrusting and intercellular matters. Although experiments had previously been made with many fibrous materials, paper was made in Europe, until the middle of the 19th century, almost entirely from rags, either linen or cotton. At that period other fibres began to be adopted as substitutes, due in part, no doubt, to insufficient supply of rags for the increasing consumption of paper, and in the hope that the advantages of these substitutes are esparto-grass, wood and straw, and these, together with flax (linnen), hemp, jute and cotton rags, form the principal raw material for the manufacture of paper.

Paper was first entirely made by hand, sheet by sheet, but in 1798 the invention of the paper machine by Louis Robert, a clerk in the employ of Messrs Didot, of the Essonne Paper Mills in France, gave a new impetus to the industry. The invention was introduced into England by Henry Forndirner (1766–1854), the proprietor of a mill at Dartford in Kent. He secured the assistance of Bryan Donkin (1768–1853), an engineer, and after much toil and perseverance, attended with great expense, for which he received no recompense, succeeded in 1803 in erecting a machine at Frogmore, Herts, which worked comparatively well. This machine, by the subsequent improvements of Dickenson, Causon, Crompton and others, has been brought to the state of perfection in which it now stands. It embraces a multitude of most ingenious and delicate operations, and produces in a few minutes, and in one continuous process from the prepared pulp, sets of paper ready for use. Moreover the paper has now gradually supplanted that made by hand for all except special purposes, such as bank-note, ledger, drawing and other high-class papers—in one word, in cases where great durability is the chief requisite.

The various uses to which paper is put in the present day are multitudinous, but the main classes may be grouped into four: (1) writing and drawing papers; (2) printing and newspapers; (3) wrapping papers; (4) tissue and cigarette papers.

The process of paper manufacture consists of two main divisions: (1) the treatment of the raw material, including cleaning, dusting, boiling, washing, bleaching and reducing to pulp;
the methods by which the prepared pulp or fibres are converted into paper ready for the market; this is paper-making proper, and includes the operations of beating, sizing, colouring, making the sheet or web, surfacing, cutting, &c.

Rags arrive at the mill from the rag merchants, either roughly sorted into grades or mixed in quality and material, and the first process is to free them from sand, dust and other impurities. To effect this they are usually passed in bulk through an ordinary revolving duster. They are then sorted into grades, and cut to a workable size about four inches square. For the best work, hand-cutting, done by women, is still preferred, but it is expensive and good machines have now been designed for this purpose. After further thrashing and dusting, the rags are ready for beating, the object of which is not only to get rid of the dirt still remaining in them and to remove some of the colouring matter, but also to decompose a particular glutinous substance which would impair the flexibility of the fibres and render them too harsh and stiff for readily making into paper. Various forms of vessels are used for boiling, but usually they are made to revolve by means of suitable gearing, and are either cylindrical or spherical (fig. 1).

Fig. 1.—Revolving Spherical Rag Boiler.

In these the rags are boiled with an alkaline solution under a low steam pressure for six to twelve hours. The next step is that of washing and 'breaking in,' which takes place in an engine called the 'breaker.' This (fig. 2) is an oblong shallow vessel or trough with rounded ends and dished bottom, usually about 13 ft. long by 6 ft. wide, by about 2 ft. 6 in. in depth, but the size varies greatly. It is partly divided along the centre by a partition or 'mid-feather,' and furnished with a heavy cast-iron roll fitted round its circumference with knives or bars of steel in bunches or clumps. Underneath the roll and fixed in the bottom of the trough is the 'plate,' consisting of a number of parallel steel bars bedded in a wooden frame. The roll can be raised or lowered on the plate so as to increase or diminish, as desired, the cutting action of the bars and plate on the material. The duty of the roll is to cut and tease out the rags, and also to act as a litter to cause the stuff to circulate round the trough. The breaker is half filled with water, and packed with the boiled rags; an ample supply of clean water is run into the engine for washing the rags, the dirty water being withdrawn by the 'drum-washer,' a hollow cylinder fitted with buckets and covered with fine wire-cloth. During the washing process the roll is gradually lowered on the plate to ease out the rags into their original fibres; this operation takes from two to four hours. As soon as all signs of the textile nature of the material are destroyed, the washing water is turned off, the drum-washer lifted, and a solution of chlorine or bleach is run in to bring the pulp up to the degree of whiteness desired, after which the rag 'half-stuff,' as it is now called, is emptied into steeps or drainers, where it is stored ready for use.

In treating esparto (the use of which for paper-making is almost confined to Great Britain) the object is to free it from all encrusting intercellular matter. To effect this it is digested with a strong solution of caustic soda under a high temperature, in boilers which are almost invariably stationary. The most usual form is that known as Sinclair's patent (fig. 3). This boiler is constructed of wrought-iron or steel plates, and holds from 23 to 3 tons of grass. It is charged through the opening at the top A, and the boiler material taken out from a door B at the side; the grass rests on a false bottom of perforated plates C, through which the liquor drains, and by means of two "vomiting" pipes, after the partial washing in the boiler. As soon as the wash water is running clear it is shut off, and the necessary quantity of a solution of bleaching powder or chlorine (averaging about 6 to 8% on the raw material) is run into the potcher, and the contents are heated by steam to a temperature of about 90° F. After about four to six hours the bleaching is complete, the drum-washer is let down, fresh water run into the potcher, and the grass washed to free it from all traces of chlorine, an operation generally assisted by the use of a little anchihlor or hyposulphite of soda. The esparto, as shipped in bales from the Spanish or African fields, is mixed with roots, weeds and other impurities; and as most of these do not boil or bleach as rapidly as the esparto they would, if not taken out of the pulp, show up in the finished paper as specks and spots. To get rid of them the esparto pulp when washed and bleached is run from the potcher into storage chests, from which it is pumped over a long, narrow serpentine settling table or "sand-table" made of wood and fitted with divisions, or "weirs," behind which the heavy impurities or weeds fall to the bottom and are caught.

The pulp is next passed over what is known as a "press-pâle" (fig. 4) or "half-stuff" machine, very similar to the wet end of a paper machine, consisting of rollers fitted with coarse-cut strainer plates, a short wire and a pair of couche and press rolls. The pulp is drawn by suction through the strainers, which keep back the finer impurities that have passed the sand-table, and then flows on to the wire-cloth in the form of a thick web of pulp. After passing through the couch and press rolls, the pulp leaves the machine with about 70% of moisture, and is ready for the heating engine, the first operation of paper-making proper. This is the usual process, though various modifications are introduced in different mills and for different purposes.

Most kinds of straw can be utilized for making into paper, the varieties generally used being rye, oat, wheat and barley; of these, the two former are the most important, as they give the largest yield in fibre. Germany and France are the two principal users of straw, which closely resembles esparto in its chemical constitution, and is reduced to a pulp by a somewhat similar process.

The picric acid papers, Germany, the United States and Canada are the countries which mainly use wood as a material for paper-making.
Two advances have been made since 1880, and wood-pulp has grown to be one of the most important fibres for paper-making purposes. Two methods are in use, known respectively as the soda or alkaline process, and the sulphonate or acid process, according as soda or sulphur (or rather sulphurous acid) forms the base of the reagent employed.

Trees of medium age are usually selected, varying from seventy to eighty years' growth and running from 8 to 12 in. in diameter. They are felled in winter and reach the mill in logs about 4 ft. long. After being freed from bark and the knots taken out by machinery, the logs are cut into small cubical chips about \( \frac{1}{2} \) to \( \frac{1}{4} \) in. in size by a revolving cutter. The chips are then bruised by being passed between two heavy iron rolls to allow the boiling solution thoroughly to penetrate them, and are conveyed to the boilers over a screen of coarse wire-cloth, which separates out the fine sawdust as well as any dirt or sand. In the soda process the wood is boiled in large revolving or upright stationary boilers for about seven or eight hours, in a similar manner to esparto and straw, though it requires much severer treatment. The steam pressure varies from 90 lb to as much as 150 lb per sq. in., and the amount of soda required is about 16% of \( \text{Na}_2\text{O} \), estimated on the barked and cleaned wood. The essential feature of the sulphite process is the employment of a solution of sulphurous acid combined with a certain amount of base, either magnesia or lime. As the acid reaction of the bisulphite solution would attack any exposed ironwork with which it comes in contact, the boilers in all cases should be lined with lead. The type of boiler employed varies according to the process adopted. The principal patents connected with the sulphite process are those of Tilghman, Ekman, Francke, Ritter-Kellner, Mitscherlich, and Partington. The subsequent operations, in both the acid and alkaline processes of washing, bleaching and straining the pulp, are all very similar to those described for esparto. Wood-pulp produced by the sulphite process differs in a marked degree from that made by the soda process; the fibre in the former case is harsher and stronger, and papers made from it are characterized by their hardness and transparency, whereas those made from soda pulp are softer and more mellow, corresponding in some way to the difference between linen and cotton fibres. Each class of pulp is largely used, both alone and mixed with other materials.

Within recent years important modifications and improvements have been adopted in the preparation of esparto and wood-half-stuff with a view to reduce the cost of manufacture and save waste of material. From the boiler to the beater the process becomes a continuous one, so that the prepared pulp requires practically no
PAPER [MANUFACTURE]

Fibres like jute, hemp, Manila, &c., are chiefly used for the manufacture of coarse papers where strength is of more importance than appearance, such as wrapping-papers, paper for telegraph-forms, &c. The boiling processes for them are similar to those used for esparto and straw. The alkaline liquors in which rags, esparto and other paper-making materials have been boiled were formerly run into the nearest water-course; but now, partly because it is insisted upon in England by the Rivers Pollution Acts, and partly because the evolution of the liquor can be made remunerative, all these liquors are preserved and the soda they contain utilized. One of the best and most economical of the simple recovery plants is that invented by Porion, a French distiller, and named after him. This consists of an evaporating chamber A, on the floor of which a few inches of the liquid to be evaporated rest. By the action of fanners B, B revolving at a high speed and dipping into the liquid, it is thrown up in a fine spray through which the conditioned gases pass to the distiller. After being concentrated in the evaporating chamber the liquid flows into the incinerating furnaces C, C, where the remaining water is driven off by the heat of the fire D, and the mass afterwards ignited to drive off the carbonaceous matter in this evaporator is Menzies and Davis's patent smell chamber E, a chamber filled with masonry in which the strongly-smelling gases from the incinerating furnace are allowed to remain at a red heat for a short time. After being recovered, the soda, in the form of crude carbonate, is latticed and re-causticized by boiling with milk of lime.

Porion's method is open, however, to the objection that the whole of the sulphur in the coal employed for the furnaces finds its way into the recovery plant, and forms sulphate of soda, thus reducing the value of the ash for boiling purposes; in addition, a considerable amount of soda is volatilized during the evaporation. By the application of the system of multiple-effect evaporation described above, the drawbacks of the Porion plant are removed and an important change has been made in the soda-recovery plant of the paper-mill. This system of multiple-effect evaporation, originally introduced by M. Rilleux, was perfected by the invention of Homer Distillery, and named after him. This consists of an evaporator for description, though other types of evaporator are now also employed, notably the ordinary vertical tube multiple-effect evaporator used for concentrating sugar liquors. The paper-recovery plant originally applied in the United States to the concentration of the waste alkaline liquors from paper-mills; it is then carried into extensive use for the manufacture and refining of sugar, the production of glucose and a variety of other purposes. The principle of multiple-effect evaporation is to utilize the latent heat of a vapour given off from a liquid under certain pressure to vaporize a further quantity of the liquid under a pressure maintained by mechanical means below that of the first. The essential feature which distinguishes the Yaryan evaporator consists in the boiling of the liquor to be treated with paper-mill in series of tubes, which constitute a coil and are heated externally by steam or vapour. The quantity of liquor entering the coil is so controlled that it is only permitted partially to fill the tubes, and thus leaves room for the instantaneous liberation of the vapour generated. As the liquor descends from tube to tube it becomes concentrated and reduced in volume until it ultimately passes into a "separator," where it impinges on a plate or disk, which causes a complete separation of the vapour and liquid; each then passes on to the next "effect," the liquid through the second coil of tubes and the vapour to the chamber enclosing them. This combination of a series of tubes, or coil, and separator constitutes a vessel or "effect," and the evaporator consists of a series, usually three or more, of such vessels, one above the other (fig. 7). The vital feature, it will be seen, is therefore that the latent heat of the original steam, after performing its function in the first effect, is utilized and then to the third or more effects, in each of which an equal amount of work is done before passing to the final condenser, which is maintained. Thus, if the total temperature be divided three times, the result is a triple-effect, if four times, a quadruple-effect. Taking an evaporation of 10 lb. of pound of paper per single-effect apparatus will evaporate 10 lb. of water, a

In England, it should be stated, it is found that both for paper liquors and liquors equally good evaporation results are obtained and the tubes kept clean by keeping them under a head of liquor, i.e., the liquor is fed into the bottom and has to ascend row by row to the top row, from which it flows to the separator.

The beaters are made to hold each about 1500 lb of dry paper and a series of four of these can make from 55 to 60 tons of paper per week.
The liquor to be concentrated is pumped from the storage tanks to the top or first effect of the Yaryan apparatus through a series of multiple-effect heaters, corresponding to the number of effects in the machine, by means of which the liquor is heated to as near the boiling point as possible of the liquor in the tubes of the first effect.

Live steam is introduced into the chamber surrounding the tubes of the first effect, and from the separator of the last effect the concentrated liquor is pumped to the incinerator.

Any form of incinerating hearth can be used in conjunction with the multiple-effect evaporator, but one very suitable to the continuous work of, and the high degree of concentration produced by, the Yaryan machine is that known as the Warren rotary furnace. This consists of a revolving iron cylinder lined with brick, about 12 ft long by 6 ft in diameter. The lining being 6 in. thicker at the inlet than at the discharge, the interior of the furnace is conical in form so that the ash gradually works forward and is eventually discharged fully burnt into trucks for storage, or on a travelling band, and so carried automatically to the dissolving or lixiviating tanks. The strong liquor runs in at one end in a slow continuous stream; by the rotation of the hearth the burning mass is carried up the sides and drops through the flame again to the bottom, much in the same manner as rags do in a revolving duster. In this way all the labour required to stir the ash of the ordinary hearth is dispensed with, and the burning material comes continuously in close contact with the flame, a complete and thorough combustion being the result. The fire-box is situated at the delivery end of the furnace, and is mounted on trucks so that it can be run back when cleaning or repairing the brickwork. The waste heat is utilized in raising steam in a steam boiler set behind the furnace, and often in keeping the thick liquor after leaving the evaporator and before entering the rotary furnace.

Paper-making proper from prepared pulp, whether of rags, esparto, wood or other raw material, may be said to begin with the operation technically known as "beating" which is carried out in one of the various forms of beating engine or "Holländer." The object of the beating is to reduce the fibres to suitable lengths and also to beat or bruise them into a stiff pulp of sufficient consistency to absorb and carry the water necessary to felt them together on the wire-cloth of the paper-machine. This operation is one of the most important and most delicate processes in the manufacture, requiring experience, skill and careful manipulation. Not only does every class of fibre demand its own special treatment, but this treatment has to be modified and varied in each case to suit the qualities and substances of the papers to be made from it.

Although there are now in use a great many forms of beating engine, they are all, more or less, modifications of the original Holländer, which in its essential details differs little from the breaking engine already described. There are usually more bars in the roll and plate than in the breaker; the bars of the plate are set at a slight angle to the fly-bars of the roll to act as shears in a similar manner to a pair of scissors. Bars and plates of bronze are frequently used for the higher grades of paper to avoid rust and dirt and to produce a softer and less violent action on the fibres. The time required for the beating process varies from 3 to 4 hours up to 10 and 12 and even more. Beating engines fitted with mechanical circulation by pumping whereby have been extensively adopted, more particularly for working esparto and the other substitutes for rags. Fig. 8 shows one of these beaters, known as the Taylor beater; the roll and plate are fixed above the trough of the beater, which has no partition or mid-feather, and from the lower end a powerful circulator or pump circulates the pulp through the beater and discharges it through a pipe in a continuous stream in front of the roll. In the pipe is fixed a two-way valve, so that when the beating operation is complete the finished pulp can be run into the stuff-chests of the paper machine. The advantages of this form of beater are that a quicker and more thorough circulation of the pulp takes place than when the roll has to do the double duty of making the pulp travel and beating it up at the same time, and thus tends to reduce the time of the operation. Also more bars can be fixed in the roll, increasing its effect on the pulp, and less power is required than when the roll revolves in the middle of the stuff as in the ordinary form of beater.

Beating engines of quite a different construction are now largely used in American mills, and also to some extent in Great Britain. These are known as "refiners," and the most important forms are the Jordan and Kingsland beaters (so called from the names of the inventors), or modifications of them. The first (fig. 9) consists of a conical plug or roll fixed on a shaft and revolving at a high rate of speed within an outer casing of corresponding shape; both the plug and the casing are furnished with steel bars parallel with the shaft, but set at slightly different angles, taking the place of the bars in the roll and plate of the ordinary beater. This conical plug or roll can be moved in either direction parallel to its axis and by this means the cutting action
of the two sets of bars can be increased or reduced. The pulp flows into the top of the beater at the smaller end of the cone through a box provided with an arrangement for regulating the flow and passes out through an opening in the casing at the other end. The roll or plate revolves at from 350 to 400 revolutions per minute, and requires a power to drive it of from 25 to 40 h.p.,

![Fig. 9.—Jordan Beater.](image)

according to the work to be done, and one engine is capable of passing as much as 1000 lb weight of dry pulp per hour. The Kingsland beater consists of a circular box or casing, on both inside faces of which are fixed a number of knives or bars of steel or bronze; inside the case is a revolving disk of metal fitted on both sides with corresponding and similar bars. The contact between the revolving and stationary bars can be regulated, as in the Jordan engine, to give the required amount of beating action on the pulp. The refiner is essentially a finishing process as an adjunct to the beating process proper. The advantages to be derived from its use are considerable saving in the time occupied in beating and the production of a more uniform and evenly divided pulp, particularly where a mixture of different fibres is used. By the use of the refiner the time occupied in the beater can be reduced by nearly one-half, the half-beaten pulp passing through the refiner from the beater to its way to the paper-machine. It is not, however, generally employed for the best kinds of paper.

During the operation of beating various materials and chemicals are added to the pulp for the purposes of sizing, loading, colouring, &c. Papers for writing and most of those for printing purposes must be rendered non-absorbent of ink or other liquid applied to them. To effect this some form of animal or vegetable size or glue must be applied to the paper, either as a coating on the finished web or sheet, or mixed with the pulp in the beating engine. The former, called “tub-sizing,” will be described later; the latter which is known as “engine-sizing” consists in filling up the interstices of the fibres with a chemical precipitate of finely-divided resin, which, when dried and heated on the cylinders of the paper-machine, possesses the property of being with difficulty wetted with water. Except in the very best qualities of paper, it is usual to add to the pulp a certain quantity of cheap loading material, such as china-clay or kaolin, or steel-hardening, a chemically precipitated form of sulphate of lime. The addition of such loading material to a moderate extent, say 10 to 15%, is not entirely in the nature of an adulterant, as it serves to close up the pores of the paper, and for ordinary writing, printing and lithographic papers renders the material so soft that it takes a much better and more even surface or gloss. But if added in excess it is detrimental to the strength and hardness of the sheet. Most materials, however well bleached, have a more or less yellowish tinge; to produce the desired white shade in the paper certain quantities of red and blue in the form of pigments or dyes must be added to the pulp. The blues usually employed are ultramarine, smalts and the aniline blues, while the red dyes are generally preparations of either cochinal or the aniline dyes. Other colours are required in the manufacture of papers of different tints, and with one or two exceptions they must be mixed with the pulp in the beater.

There are two distinct processes of producing the finished paper from the pulp, known respectively as “hand-made” and “machine-made.” The expense of manufacture of hand-made paper and the consequent high price render it too costly for ordinary use; the entire process on the machine occupies a few minutes, while in the ordinary state of the weather it could not be done by hand in less than a week.

A brief description of the hand-made process will suffice and it will at the same time facilitate the right comprehension of the machine process. Only the finest qualities of rags are used for hand-made paper; and the preparation of the half-stuff is the same as that already described under treatment of rags. The pulp after being prepared in the beating engine is run into large chests from which the vat is supplied; before reaching this it is strained as on the paper-machine (see below). The sheet of paper is made on a mould of fine wire-cloth with a removable frame of wood to keep the pulp from running off, extending slightly above the surface of the mould, called the “deckel.” To form the sheet, the paper-maker dips the mould into a vat (see fig. 10) containing the prepared pulp, lifting it up just so much as will make a sheet of the required thickness; as soon as the mould is removed from the vat, the water begins to drain through the wire-cloth and to leave the fibres on the surface in the form of a coherent sheet, the felting or interwining being assisted by a lateral motion or “shake” given to the mould by the workman; the movable deckel is then taken off, and the mould is given to another workman, called the “coucher,” who turns it over and presses it against a felt, by this means transferring or “couching” the sheet from the wire to the felt. A number of the sheets thus formed are piled one above another alternately with pieces of felt, and the whole is subjected to strong pressure to expel the water; the felts are then removed and the sheets are again pressed and dried, when they are ready for sizing. Any pattern or name required in the sheet is obtained by making the wire-cloth mould in such a way that it is slightly raised in those parts where the pattern is needed (fig. 11); consequently less pulp lodges there and the paper is proportionately thinner, thus showing the exact counterpart of the pattern on the mould; such are known as “watermarks.” The expense of manufacturing paper in this way is very much greater than by machinery; but the gain in strength, partly owing to the time allowed to the fibres to knit together, and partly to the free expansion and contraction permitted them in drying, still maintains a steady demand for this class of paper.

The paper-machine (fig. 12) consists essentially of an endless mould of fine wire-cloth on which the pulp flows and on which a continuous sheet of paper is formed; the sheet then passes through a series of press rolls and over a number of steam-heated cylinders until it is dry. From the beating engines, the pulp is emptied
into storage tanks or stuff-chests, fitted with revolving arms or agitators; from these the pulp is pumped into a long upright supply box at a higher level, called the stuff-box, which communicates with the sand trap or table by means of a regulating valve. With the pulp a certain amount of water is allowed to flow on to the sand trap so as to dilute it sufficiently to form on the wire-cloth of the pulp-machine. The sand trap consists of an elevated table in which is sunk a shallow serpentine channel lined on the bottom with rough felt and divided throughout its length by a number of small strips of wood, behind which the impurities collect as the pulp flows over them on its way to the strainers.

The strainers are made of plates of brass or some hard and durable composition with fine parallel slits cut in them, through which the fibres pass, all knots and improperly divided portions remaining behind; the pulp is made to pass through them by the rapid vibration of the plates themselves or by a strong suction underneath them, or sometimes by a combination of the two. From the strainers the pulp flows into a long wooden box or trough, of the same width as the paper machine, called the "breast-box," and thence on to the wire-cloth. The wire consists of a continuous woven brass cloth, supported horizontally by small brass rolls, called "tube-rolls," carried on a frame; it is usually 40 to 50 ft. long and is stretched tight over two rolls, one at each end of the frame, called respectively the "breast-roll" and the "lower-couch roll." The ordinary gauge for the wire-cloth is 66 meshes to the inch for writings and printings; finer wires are sometimes used, however, up to 80 to the inch; for lower grades the mesh is coarser. The water, mixed with the pulp, flows from the wire-cloth by gravitation along the lines of contact between it and the tube-rolls; this water, which contains a considerable percentage of fibres, especially from finely beaten pulp, drops into a flat copper or wooden tray, from which it flows into a tank and is pumped up with the water for diluting the pulp so that none of it shall be wasted. From the tube-rolls the wire conveys the pulp over a pair of suction-boxes for extracting the remaining water from the web. The width of the web of paper is determined by two continuous strips of vulcanized rubber about 1/2 in. square, one on each side of the wire, called the "deckel-strap"; the distance between these strips can be increased or diminished; they serve to guide the pulp from the frame of the machine from the breast-roll to the first section, and bring on it a pair of strong fibres, and is capable of a slight horizontal motion imparted by a horizontal connecting-rod, one end of which is eccentrically keyed on to the face of a rapidly-revolving disk driven by a pair of speed-cones, so that the speed of the shake can be altered. The object of the shake is to interlace the fibres together, but it also assists in keeping the water from passing through the wire too rapidly before the paper has been properly formed. Most machines have two suction-boxes with the "dandy-roll" revolving between them on the top of the pulp (so called because it can be made to give to the paper any desired "kinks," markings). The "dandy-roll" (Fig. 13) is a light skeleton cylinder covered with wire-cloth on which small pieces of wire are soldered representing the watermark to be reproduced in the paper. From the last suction-box the half-dried sheet of pulp passes between the "couch-rolls," so called from the corresponding operation of couching in hand-made paper, which, by pressing out most of the remaining moisture, impart sufficient consistency to the paper to enable it to leave the wire; both rolls are covered with a felt jacket, and the top one is provided with levers and weights to increase or diminish the pressure on the web. The paper is now fully formed, and is next carried by means of endless felted belts between two and sometimes three pairs of press-rolls to extract the remaining moisture, and to obliterate as much as possible the impression of the wire-cloth from the underside of the web. The web of paper is finally dried by passing it over a series of hollow steam-heated drying cylinders driven one from the other by gearing. The slower and more gradual the drying process the better, as the change on the fibres of the web due to the rapid contraction in drying is thereby not so excessive, and the heat required at one time is not so great nor so likely to damage the quality of the paper; the heating surface should therefore be as large as possible, and a great number of cylinders is required now that the machines are driven at high speeds. The cylinders are so placed that both surfaces of the web are alternately in contact with the heating surface. All the cylinders except the first two or three with which the moist paper comes in contact and where the greatest evaporation occurs, are encased by continuous travelling felts. The drying cylinders are generally divided into two sets one upon another, and one or more of which are bored and heated by steam, called "nip-rolls," or "smoothers," the purpose of which is to flatten or smooth the surface of the paper while in a partially dry condition. Before being reeled up at the end of the machine the web of paper is passed through one or more sets of "calendars," according to the degree of surface or smoothness required. These calenders consist of a vertical stack of chilled iron rolls, generally five in number, revolving one upon another, and one or more of which are bored and heated by steam; pressure can be applied to the stack as required by means of levers and screws. The web of paper is now wound up in long reels at the end of the machine.

Paper-machines are now usually driven by two separate steam engines. The first, running at a constant speed, drives the strainers, pumps, shake motion, &c., while the second, working the paper-machine, varies in speed according to the rate at which it requires
to be driven. The power consumed by the two engines will average from 40 to 100 h.p. The drying cylinders of the paper-machine form a convenient and economical condenser for the two steam-engines, and it is customary to exhaust the driving engine into the drying cylinders and utilize the latent heat in the steam for drying the paper, supplementing the supply when necessary with live steam. The speed of the machine has frequently to be altered while in motion. An alteration of a few feet per minute can be effected by changing the driving-speed of the steam-engine governor; for a greater change the machine must be stopped and other driving-wheels substituted. Arrangements are made in the driving-gear by which the various parts of the machine can be slightly altered in speed relatively to one another, to allow for the varying contraction or expansion of the paper web for different kinds and thicknesses of paper. The average speed of a paper-machine on fine writing-papers of medium weight is from 60 to 90 ft. per minute, but for printing-papers, newspapers, &c., the machine is driven from 120 up to as much as 300 and 400 ft. per minute. The width of machines varies greatly in different mills, from about 60 in. to as much as 150 in. wide. Mills running on higher classes of papers as a rule use narrow machines, as these make a closer and more even sheet of paper than wide ones. On fine writing-papers an average machine will make from 20 to 40 tons per week, while for common printing and newspapers the weekly output will amount to 50 to 70 tons.

All hand-made papers, and many of the best classes of machine-made papers, instead of being sized in the beater with a preparation of resin are what is called "tub-sized," that is, coated with a solution of gelatin. Such papers, when machine-made, are reeled off the machine straight from the drying cylinders in the rough state. The web is then led slowly through a tub or vat containing a heated solution of animal glue or gelatin mixed with a certain amount of alum; after passing through a pair of brass rolls to squeeze out the superfluous size, the web is reeled up again and allowed to remain for some time for the size to dry. This paper is then led by means of continuous travelling tapes over a long series of open skeleton drums, about 4 ft. in diameter, inside which revolve fans for creating a circulation of hot air; rows of steam-pipes underneath the line of drums furnish the heat for drying. Slow and gradual drying is essential to this process to get the full benefit of the sizing properties of the gelatin. In hand-made papers, the sheets are passed by handfuls of three or five on an endless felt through the gelatin solution and between a pair of rolls, and then slowly dried on rope lines or "trubbles" in a steam-heated and well-ventilated loft.

The cheaper kinds of paper are glazed on the paper-machine in the calenders as before described. For the better class or very highly-glazed papers and those that are tub-sized, a subsequent glazing process is required; this is effected by sheet or plate-glazing and by super-calendering or web-glazing. The plate-glazing process is adopted mainly for the best grades of writing-papers, as it gives a smoother, higher and more permanent gloss than has yet been imitated by the roll-calender. In this method each sheet is placed by hand between two zinc or copper plates until the super-calendering rolls are applied. This handful of about two quire or 48 sheets of paper, is then passed backwards and forwards between two chilled-iron rolls pressed together, the web being brought to bear upon the top roll by levers and weights, or by a pair of screws; the pressure on the rolls, and the number of times the handfull is passed through, are varied according to the amount of gloss required on the paper. One of the surfaces of the web is then brought to bear upon the plate-glazed surface, partly as a matter of economy in cost, but principally for the high surfaces required on papers for books and periodicals to show up wood-cuts and photographic illustrations. It usually consists of a stack of chilled cast-iron rolls, alternating with rolls of compressed cotton or paper so that the web at each nip is between cotton and iron; it will be seen from the illustration that there are two cotton rolls together in the stack for the purpose of reversing the action on the paper and so making both sides alike; hence pressure is applied to the rolls at the top by compound levers and weights or screws. A very high surface can be quickly given to paper by friction with the assistance of heat; the process is known as "burnishing," and is used mostly for envelope papers and wrapping papers where one surface only of the web is required to be glazed. It is produced by the friction of a chilled-iron roll on one of cotton or paper, the ratio of the revolutions being as 4 to 5; steam is admitted to the burning iron roll.

Except for special purposes, such as for use in a continuous process in a writing-paper machine, the paper is generally sized in the mill in the form of sheets. A number of reels of paper is hung up on spindles between two upright frames to feed the cutting-machine (see fig. 15): the various webs of paper are drawn forward together through two small rollers, and ripped into widths of the required size by means of a number of pairs of circular knives or "slitters"; they then pass between another pair of rollers, and over a long dead-knife fixed across the cutting-machine, on which they are cut into sheets by another transverse knife fastened to a revolving and driven turret. The sheets are then carried away by a large pair of shears. The cut sheets then fall upon an endless travelling felt, from which they are stacked in piles by boys. It is often necessary, as in the case of water-marked papers, that the sheets should be cut with great exactness so that the designs shall appear
different shades of colour, &c.; this entails considerable time and expense as each sheet has to be passed in review separately.

Sheeting. This sorting is usually performed by women. Papers are as a rule sorted into three different qualities, known in the trade respectively as "perfect," "retire" and "broke"; the best of the defective sheets form the second quality "retire," a term derived from the French word retrait (to draw out), and are sold at a reduced price; sheets that are torn or damaged or too badly marked to pass for the third quality "broke," are returned to the mill to be repulped as waste paper.

Paper is sold in sheets of different sizes and is made up into reams containing from 450 to 516 sheets; these sizes correspond to different trade names, such as foolscap, post, demy, royal, &c.; the following are the ordinary sizes:

With the enormously increased production of paper and the great reduction in price within recent years, it has been found that the "science" of paper-making has scarcely advanced with the same rapid strides as the art itself. Although a sheet of paper made to-day differs little as a fabric from the papers of earlier epochs, the introduction of new and cheaper forms of vegetable fibres and the auxiliary methods of treating them have caused a great change in the quality, strength and lasting power of the manufactured article. The undue introduction of excessive quantities of mechanical or ground wood-pulp in the period 1875-1880 into the cheaper qualities of printing-papers, particularly in Germany, first drew attention to this matter, since it was noticed that books printed on paper in which much of this material had been used soon began to discolor and turn brown where exposed to the air or light, and after a time the paper became brittle. This important question began to be scientifically investigated in Germany about the year 1885 by the Imperial Testing Institution in Berlin. A scheme of testing papers has been formulated and officially adopted by which the chemical and physical properties of different papers are compared and brought to numerical expression. The result of these investigations has been the fixing of certain standards of quality for papers intended for different purposes. These qualities are grouped and defined under such heads as the following:

- **Strength**, expressed in terms of the weight or strain which the paper will support.
- **Elasticity and texture**, measured by elongation under strain and resistance to crumpling or rubbing.
- **Bulk**, expressed in the precise terms of specific gravity or weight per unit of volume.

Of not less importance are the qualities which belong to paper as a chemical substance or mixture, which are: (1) its actual composition; (2) its liability to undergo whatever changes in the conditions of storage and use it may be subjected to. For all papers to be used for any permanent purpose these physical and chemical qualities must ultimately rank as regulating the consumption and production of papers.

In England and Wales in 1900 there were 1,221 mills, using 499 machines and 99 vats for hand-made paper; in Scotland, 99 mills and 111 machines; in Ireland, 7 mills and 11 machines. The rough estimate of the amount of capital embarked in the industry may be formed on the basis that average mills would represent from £20,000 to £30,000 and upwards per machine.

The table at foot of page shows the amounts and values of the British imports and exports of paper and paper-making materials in 1907.

**India Paper.**—This name is given to a very thin and light but tough and opaque kind of paper, sometimes used for printing books—especially Bibles—of which it is desirable to reduce the bulk and weight as far as possible without impairing their durability or diminishing their type. The name was originally given in England, about the middle of the 13th century, to a soft absorbent paper of a pale buff shade, imported from China, where it was made by hand on a paper-making frame generally similar to that used in Europe. The name probably originated in the prevailing tendency, down to the end of the 18th century, to describe as "Indian" anything which came from the Far East (cf. Indian ink). This so-called India paper was used for printing the earliest and finest impressions of engravings, hence known as "India proofs." The name of India paper is now chiefly associated with European (especially British) machine-made, thin, opaque printing papers used in the highest class of book-printing. In 1841 an Oxford graduate brought home from the Far East a small quantity of extremely thin paper, which was manifestly more opaque and tough, for its weight, than any paper then made in Europe. He presented it to the Oxford University Press, and in 1842 Thomas Combe, printer to the University, used it for 24 copies of the smallest Bible then in existence—Diamond 24mo. These books were scarcely a third of the usual thickness, and were regarded with great interest; one was presented to Queen Victoria, and the rest to other persons. Combe tried
PAPHLAGONIA—PAPHOS

in vain to trace the source of this paper. In 1874 a copy of this Bible fell into the hands of Henry Frowde, and experiments were instituted at the Oxford University paper-mills at Wobercote with the object of producing similar paper. On the 24th of August 1875 an impression of the Bible, similar in all respects to that of 1842, was placed on sale by the Oxford University Press. The feat of compression was regarded as astounding, the demand was enormous, and in a very short time 250,000 copies of this "Oxford India paper Bible" had been sold. Many other editions of the Bible, besides other books, were printed on the Oxford India paper, and the marvels of compression accomplished by its use created great interest at the Paris Exhibition of 1900. Its strength was as remarkable as its lightness; volumes of 1500 pages were suspended for several months by a single leaf, as thin as tissue, and when they were examined at the close of the exhibition, it was found that the leaf had not started, the paper had not stretched, and the volume closed as well as ever. The paper, when subjected to severe rubbing, instead of breaking into holes like ordinary printing paper, assumed a texture resembling chamois leather, and a strip 3 in. wide was found able to support a weight of 28 lb. without yielding.

The success of the Oxford India paper led to similar experiments by other manufacturers, and there were in 1910 nine mills (two each in England, Germany, France, Holland, and Italy) in which India paper was being produced. India paper is mostly made upon a Fourdriner machine in continuous lengths, in contradistinction to a hand-made paper, which cannot be made of a greater size. The latter is not of uniform quality, and the production was in the past usually limited to the use of the hands, for the mechanical pulp. The opacity of modern India paper, so remarkable in view of the thinness of the sheet, is mainly due to the admixture of a large proportion of mineral matter which, combined with the yellowish tint imparted by the fibres, makes the paper of a characteristic dull yellowish color. The advantage gained by the use of India paper is the diminution of the weight and bulk of a volume—usually to about one-third of those involved by the use of good ordinary printing paper—without any alteration in the size and legibility of its type and without any loss of opacity, which is an absolute necessity in all papers used for class-book paper printing to prevent the type showing through.

PAPHLAGONIA, an ancient district of Asia Minor, situated on the Euxine Sea between Bithynia and Pontus, separated from Galatia by a prolongation to the east of the Bithynian Olympus. According to Strabo, the river Parthenius formed the western limit of the region, which was bounded on the east by the Halys. Although the Paphlagonians play scarcely any part in history, they were one of the most ancient nations of Asia Minor (IIiad, ii. 851). They are mentioned by Herodotus among the races conquered by Croesus, and they sent an important contingent to the army of Xerxes in 480 B.C. Xenophon speaks of them as being governed by a prince of their own, without any reference to the neighboring satraps, a freedom due, perhaps, to the nature of the country, with its lofty mountain ranges and difficult passes. At a later period Paphlagonia passed under the Macedonian kings, and after the death of Alexander the Great it was assigned, together with Cappadocia and Mysia to Eumenes. It continued, however, to be governed by native princes, and the Euphrates formed its southern boundary. After the fall of the great Mithridates III. (302—266 B.C.), it was not till that of Pharnaces I. that Sinope fell into their hands (183 B.C.). From this time the whole province was incorporated with the kingdom of Pontus until the fall of the great Mithridates (65 B.C.). Pompey united the coast districts of Paphlagonia with the province of Bithynia, but left the interior of the country under the native princes, until the dynasty became extinct and the whole country was incorporated in the Roman empire. All these rulers appear to have borne the name of Pylaemenes, as a token that they claimed descent from the chieftain of that name who figures in the Iliad as leader of the Paphlagonians. Under the Roman Empire Paphlagonia, with the greater part of Pontus, was united into one province with Bithynia, as we find to have been the case in the time of the younger Pliny; but the name was still retained by geographers, though its boundaries are not distinctly defined by Ptolemy. It reappears as a separate province in the 5th century (Hierocles, Synecdem. c. 33).

The ethnic relations of the Paphlagonians are very uncertain. It seems perhaps most probable that they belonged to the same race as the Cappadocians, who held the adjoining province of Pontus, and were undoubtedly a Semitic race. Their language, however, would appear from Strabo to have been distinct. Equally obscure is the relation between the Paphlagonians and the Eneti or Heneti (mentioned in connexion with them in the Homeric catalogue) who were supposed in antiquity to be the ancestors of the Veneti, who dwelt at the head of the Adriatic. But no trace is found in historical times of any tribe of that name in Asia Minor.

The greater part of Paphlagonia is a rugged mountainous country, but it contains fertile valleys, and produces great abundance of fruit. The mountains are clothed with dense forests, which are conspicuous for the quantity of boxwood which they furnish. Hence its coasts were from an early period occupied by Greek colonists. An important bathing city of Sinope, founded from Miletus about 630 B.C., stood on the coast. Amastris, a few miles east of the Parthenius, became important under the Macedonian monarchs; while Amisos, a colony of Sinope, situated a short distance east of the Halys, and therefore not strictly in Paphlagonia as defined by Strabo, rose to be almost a rival of its parent city. The most considerable towns of the interior were Gangra, in ancient times the capital of the Paphlagonian kings, afterwards called Germanicopolis, situated near the frontier of Galatia, and Rasinopolis, in the valley of the Amnis (a tributary of the Halys), near which were extensive mines of the mineral called by Strabo sandarake (red arsenic), which was largely exported from Sinope.

PAPHOS, an ancient city and sanctuary on the west coast of Cyprus. The sanctuary and older town (Palapaphos) lie at Kouklia, about 20 m. west of Limasol, about a mile inland on the left bank of the Diorizo River (anc. Bocarus), the mouth of which formed its harbour. New Paphos (Papho or Baffo), which had already superseded Old Paphos in Roman times, lies 10 m. farther west, and 1 m. south of modern Kitima, at the other end of a fertile coast-plain. Paphos was believed to have been founded either by the Arcadian Agapenor, returning from the Trojan War (c. 1180 B.C.), or by his reputed contemporary Cinys, whose clan retained royal privileges down to the Ptolemaic conquest of Cyprus in 295 B.C., and held the Paphian priesthood till the Roman occupation in 58 B.C. The town certainly dates back to the close of the Mycenaean Bronze age, and had a king Eteandros among the allies of Assur-bani-pal of Assyria in 668 B.C.1 A later king of the same name is commemorated by two inscribed bracelets of gold now in the Metropolitan Museum of New York. In Hellenic times the kingdom of Paphos was only second to Salamis in extent and population, and was considered on those of Silius and Cyrenae. Paphos owes its splendid fame to the cult of the "Paphian goddess"

2. Athan. e. graceos, 1o. On all these cults see J. G. Frazer, Adonis, Attis, and Venus (London, 1900, 1890).
3. Herod. i. 105; see further Astarte, Aphrodite.
shown in this city. She was worshipped, under the form of a conical stone, in an open-air sanctuary of the usual Cypriote type (not unlike those of Mycenaean Greece), the general form of which is known from representations on late gems, and on Roman imperial coins; its ground plan was discovered by excavation in 1883. In such a conical temple was the shrine of the goddess, and was rebuilt more than once; in Roman times it consisted of an open court, irregularly quadrangular, with porticoes and chambers on three sides, and a gateway through them on the east. The position of the sacred stone, and the interpretation of many details shown on the gems and coins, remain uncertain. South of the main court lie the remains of what may be either an earlier temple, or the traditional tomb of Cinyras, almost wholly destroyed except its west wall of gigantic stone slabs.

After the foundation of New Paphos and the extinction of the Cinyrad and Ptolemaic dynasties, the importance of the Old Town declined rapidly. Though restored by Augustus and renamed Sebastê, after the great earthquake of 13 B.C., and visited in state by Titus before his Jewish War in 70 B.C., it was ruined and desolate by Jerome's time; but the prestige of its priest-kings partly lingered in the exceptional privileges of the patriarch of the Cypriote Church (see Cyprus, Church of).

New Paphos became the administrative capital of the whole island in Ptolemaic and Roman days, as well as the head of one of the four Roman districts; it was also a flourishing commercial city in the time of Strabo, and famous for its oil, and for “diamonds” of medicinal power. There was a festal procession thence annually to the ancient temple. In A.D. 696 it was attacked and destroyed by the Saracens. The site shows a Roman theatre, amphitheatre, temple and other ruins, with part of the city wall, and the moles of the Roman harbour, with a ruined Greek cathedral and other medieval buildings. Outside the walls lies another cullumarian building. Some rock tombs had doubtless been the ancient shrines of local deities of Cypriote character.

PAPIA, of Hierapolis in Phrygia, one of the “Apostolic Fathers” (q.v.). His Exposition of the Lord's Oracles, the prime early authority as to the Gospels of Matthew and Mark (see Gospels), is known only through fragments in later writers, chiefly Eusebius of Caesarea (H. E. iii. 39). The latter had a bias against Papias on account of the influence which he had in perpetuating, through Irenaeus and others, belief in a human origin of Christ's teaching which was opposed to the teachings of small mental capacity, who took the figurative language of apostolic traditions for literal fact. This may have been so to some degree; but Papias (whose name itself denotes that he was of the native Phrygian stock, and who shared the enthusiastic religious temper characteristic of Phrygia, see Montanism) was nearer in spirit to the actual Christianity of the sub-apostolic age, especially in Western Asia, than Eusebius realized. In Papias's circle the exceptional in connexion with Christianity, he seemed quite normal. Eusebius quotes from him the resurrection of a dead person in the experience of "Philip the Apostle"—who had resided in Hierapolis, and from whose authors Papias derived the story—and also the dying of Philip, "when Philip to the test by the unbeliever," says Philip of Side, by "Justus, surnamed Barsabbas" without ill effect. Papias

5. Perhaps this is the basis of a clause in the secondary ending to John's Gospel (xiv. 18).
for plaster in the moulded ornaments of roofs and walls, and the ordinary roofing felts, too, are very closely allied in their composition to papier mâché. Under the name of ceramic papier mâché, architectural enrichments are also made of a composition derived from paper pulp, resin, glue, a drying oil and acetate of lead. Among the other articles for which the substance is used may be enumerated masks, dolls’ heads and other toys, anatomical and botanical models, artists’ lay figures, milliners’ and clothiers’ blocks, mirror and picture-frames, tubes, &c.

The materials for the commoner classes of work are old waste and scrap paper, repulsed and mixed with a strong size of glue and paste. To this very often are added large quantities of ground chalk, clay and fine sand, so that the preparation is little more than a plaster held together by the fibrous pulp. Wood pulp (from Sweden) is now extensively used for making papier mâché. The finest class of work Clay’s original method is retained. It consists of soaking several sheets of a specially made paper in a strong size of paste and glue, pasting these together, and pressing them in the mould of the article to be made. The moulded mass is dried in a stove, and, if necessary, further similar layers of paper are added, till the required thickness is attained. The dried object is hardened by dipping in oil, after which it is varnished and prepared for japanning and ornamentation. For very delicate relief ornaments, a purer papier mâché is prepared by mixing the 등을 with powder mixed with paste and a proportion of potash, all of which are thoroughly incorporated into a fine smooth stiff paste. The numerous processes by which surface decoration is applied to papier mâché differ in no way from the application of like ornament to wooden or other surfaces. Papier mâché for its weight is an exceedingly tough, strong, durable substance, possessed of some elasticity, little subject to warp or fracture, and unaffected by damp.

PAPIN, DENIS (1647-c. 1712), French physicist, one of the inventors of the steam-engine, was a native of Blois, where he was born on the 22nd of August 1647. In 1661 or 1662 he entered upon the study of medicine at the university of Angers, where he graduated in 1669. Some time prior to 1674 he removed to Paris and assisted Christian Huygens in his experiments with the air-pump, the results of which (Experiences du Vide) were published at Paris in that year, and also in the form of five papers by Huygens and Papin jointly, in the Philosophical Transactions for 1675. Shortly after the publication of the Experiences du Vide, Papin, having inherited a large fortune, was hospitably received by Robert Boyle, whom he assisted in his experiments and with his writings. About this time also he introduced into the air-pump the improvement of making it with double barrels, and replacing by the two valves the turncock hitherto used; he is said, moreover, to have been the first to use the plate and receiver. Subsequently he invented the condensing-pump, and in 1680 he was admitted, on Boyle’s nomination, to the Royal Society. In the previous year he had exhibited to the society his famous “steam digester, or engine for softening bones,” afterwards described in a tract published at Paris and entitled La Manière d’amollir les os et de faire couler toutes sortes de viandes en fort peu de temps et à peu de frais, with une description de la marmille, ses propriétés et ses usages. This device consisted of a vessel provided with a tightly fitting lid, so that under pressure its contents could be raised to a high temperature; a safety valve was used, for the first time, to guard against an excessive rise in the pressure. After further experiments with the digester he accepted an invitation to Venice to take part in the work of the recently founded Academy of the Philosophical and Mathematical Sciences. Returning to Paris, he returned to London and received from the Royal Society an appointment as “temporary curator of experiments,” with a small salary. In this capacity he carried on numerous and varied investigations. He discovered a siphon acting in the same manner as the “siphon wirtembergicus” (Phil. Tr., 1658), and also constructed a model of an engine for raising water from a river by means of pumps worked by a water-wheel driven by the current. In November 1687 he was appointed to the chair of mathematics in the university of Marburg, and here he remained until 1696, when he removed to Cassel. From the time of his settlement in Germany he carried on an active correspondence with Huygens and Leibnitz, which is still preserved, and in one of his letters to Leibnitz, in 1698, he informed him how he was engaged on a machine for raising water to a great height by the force of fire; in a later communication he speaks also of a little carriage he had constructed to be propelled by this force. Again in 1702 he wrote about a steam “ballista,” which he anticipated would “promptly compel France to make an enduring peace.” In 1705 Leibnitz sent Papin a sketch of Thomas Savery’s engine for raising water, and this stimulated him to further exertions, which resulted two years afterwards in the publication of the Ars nova ad aquam ignis adminiculio efficacissime descendam (Cassel, 1707), in which his high-pressure boiler and its applications are described (see STEAM ENGINE). In 1707 he resolved to quit Cassel for London, and on the 24th of September of that year he sailed with his family from Cassel in an ingeniously constructed boat, propelled by paddle-wheels, to be worked by the crew, with which he apparently expected to reach the mouth of the Weser. At Münden, however, the vessel was confiscated at the instance of the boatmen, who objected to the invasion of their exclusive privileges in the Weser navigation. Papin, on his arrival in London, found himself without resources and almost without friends; applications to the Royal Society for grants of money were made in vain, and he discharged those on his account probably about the beginning of 1712. His name is attached to the principal street of his native town, Blois, were also he is commemorated by a bronze statue.

The published writings of Papin, besides those already referred to, consist for the most part of a large number of papers, principally on hydraulics and pneumatics, contributed to the Journal des savans, the Nouvelles de la république des lettres, the Philosophical Transactions, and the Acta eruditorum; many of them were collected by himself into a Fasciculus dissertationum (Marburg, 1695), of which he published also a translation into French, Recueil de diverses pièces touchant quelques nouvelles machines (Cassel, 1695). His correspondence with Leibnitz and Huygens, along with a biography, was published by Dr Ernst Gerland (Leibnizens und Huygens Briefwechsel mit Papin, nebst der Biographie Papins (Berlin, 1881). See also L. de la Sausaute and E. Péan, La Vie et les ouvrages de Denis Papin (Paris, 1869); and Baron Emout, Denis Papin, sa vie et ses ouvrages (4th ed., 1888).

PAPINEAU, LOUIS JOSEPH (1786—1871), Canadian rebel and politician, son of Joseph Papineau, royal notary and member of the house of Assembly of Lower Canada, was born at Montreal on the 16th of October 1786. He was educated at the seminary of Quebec where he had a good classical and literary education and also received a little persuasive oratory. He was called to the bar of Lower Canada on the 19th of May 1810. On the 18th of June 1808 he was elected a member of the House of Assembly of the province of Lower Canada, for the county of Kent. In 1815 he became speaker of the house, being already recognized as the leader of the French Canadian party. At this time there were many grievances in the country which demanded redress; but each faction was more inclined to insist upon the exercise of its special rights than to fulfill its common responsibilities. In December 1820 Lord Dalhousie, governor of Lower Canada, appointed Papineau a member of the executive council; but Papineau, finding himself without real influence on the council, resigned in January 1823. In that year he went to England to protest on behalf of the French Canadians against the projected union of Upper and Lower Canada, a mission in which he was successful. Nevertheless his opposition to the government became more and more pronounced, till in 1827 Lord Dalhousie refused to confirm his appointment to the speakership, and resigned his governorship in protest of this refusal; and in 1833 he was expelled from the executive council. Matters came to a head when the legislative assembly of Lower Canada refused supplies and Papineau arranged for concerted action with William Lyon Mackenzie, the leader of the reform party in Upper Canada. In 1835 Lord Gosford, the new governor of Lower Canada, was instructed by the cabinet in London to inquire into the alleged grievances of the French Canadians. But the attitude
of the opposition remained no less hostile than before, and in March 1837 the governor was authorized to reject the demand for constitutional reform and to apply public funds in his control to the purposes of government. In June a warning proclamation by the governor was answered by a series of violent speeches by Papineau, who in August was deprived of his commission in the militia.

Papineau had formerly professed a deep reverence for British institutions, and he had acquired a theoretical knowledge of the constitution, but he did not possess the qualities of a statesman, and consequently in his determination to apply the strict letter of the constitution he overlooked those elements and compensating forces and powers which through custom and usage had been incorporated in British institutions, and had given them permanence. In his earlier career he had voiced the aspirations of a section of the people at a time when it appeared to them that their national existence was threatened. In the course of time party strife became more bitter; real issues were lost sight of; and Papineau, falling in with the views of one O'Callaghan, who distrusted everything British, became an annexionist. Realizing that his cause was not advanced by this, he gave up the threatening attitude which caused men of sober judgment to waver in their allegiance. These men he denounced as traitors; but a band of youthful enthusiasts encouraged their leader in his revolutionary course. The bishop of Montreal and of Quebec, and a large number of the citizens, protested, but nothing less than bloodshed would satisfy the misguided patriots. On the 23rd of October 1837 a meeting of delegates from the six counties of Lower Canada was held at St Charles, at which resistance to the government by force of arms was decided upon, and in which Papineau took part. In November preparations were made for a general stampede at Montreal, and on the 7th of the month Papineau's house was sacked and a fight took place between the constitutional and the sons of liberty. Towards the middle of November Colonel Gore was commanded to effect the arrest of Papineau and his principal adherents on a charge of high treason. A few hundred armed men had assembled at Saint Denis to resist the troops, and early on the morning of the 22nd of November hostilities commenced, which were maintained for several hours and resulted in many casualties. On the eve of the fray Papineau sought safety in flight, followed by the leading spirits of the movement. On the 1st of December 1837 a proclamation was issued, declaring Papineau a rebel, and placing a price upon his head. He had found shelter in the United States, where he remained in safety throughout the whole period of the fighting. The rebellion broke out afresh in the autumn of 1838, but it was soon repressed. Those taken in open rebellion were deported by Lord Durham to save them from the scaffold; and although 90 were condemned to death only 12 were executed.

Attempts have been made to transfer the responsibility for the act of violence to O'Callaghan and other prominent leaders in the revolt; but Papineau's own words, “The patriots of this city would have avenged the massacre but they were so poor and so badly organized that they were not fit to meet the regular troops," prove that he did not desire a direct recourse to arms. Writing of the events of 1837 in the year 1848 he said: “The smallest success at Montreal or Toronto would have induced the American government, in spite of its president, to support the movement.” It would thus seem that he was intriguing to bring about intervention by the United States with a view to annexation; and as the independence of the French Canadian race, which he professed to desire, could not have been achieved under the constitution of the American republic, it is inconsistent to regard his services to his fellow-countrymen as those of a true patriot. Papineau, in pursuing towards the end a policy of blind passion, overlooked real grievances, and prevented remedial action. After the rebellion relief was accorded because the obstacle was removed, and it is evident that a broad-minded statesman, or a skillful diplomat, would have accomplished more for French Canada than the fiery eloquence and dubious methods of a leader who plunged his followers into the throes of war, and who, after the defeat, cherished the hopes of the movement. From 1839 to 1847 Papineau lived in Paris. In the latter year an amnesty was granted to those who had participated in the rebellion in Canada; and, although in June 1838 Lord Durham had issued a proclamation threatening Papineau with death if he returned to Canada, he was now admitted to the benefit of the amnesty. On his return to Canada, when the two provinces were now united, he became a member of the lower house and continued to take part in public life, demanding “the independence of Canada, for the Canadians never expect justice from England, and to submit to her would be an eternal disgrace.” He unsuccessfully agitated for the re-division of upper and lower Canada, and in 1854 retired into private life. He died at Montebello, in the province of Quebec, on the 24th of September 1871.

(A. G. D.)

PAPIANUS (AELMIUS PAPIANUS), Roman jurist, was magister libellorum and afterwards praetorian prefect under Septimius Severus. He was an intimate friend of the emperor, whom he accompanied to Britain, and before his death Severus specially commended his two sons to his charge. Papianus tried to keep peace between the brothers, but with no better result than to exist a few months after Caracalla, to which he fell a general slaughter of Geta's friends which followed the fratricide of a.d. 212. The details are variously related, and have undergone legendary embellishment, but the murder of Papianus, which took place under Caracalla's own eyes, was one of the most disgraceful crimes of that tyrant. Little more is known about Papianus. He was perhaps a Syrian by birth, for he is said to have been a kinsman of Severus's second wife, Julia Domna; that he studied law with Severus under Scævola is asserted in an interpolated passage in Suetonius (Caracal., c. 8).

Papianus's place and work as a jurist are discussed under Roman Law.

PAPPENHEIM, GOTTFRIED HEINRICH, COUNT OF (1594-1632), imperial field marshal in the Thirty Years' War, was born on the 20th of May 1594 at the little town of Pappenheim on the Altmühl, now in Bavaria, the seat of a free lordship of the empire, from which the ancient family to which he belonged derived its name. He was educated at Altдорf and at Tübingen, and subsequently travelled in southern and central Europe, mastering the various languages, and thereby preparing for his stay in these countries which led him eventually to adopt the Roman Catholic faith (1614), to which he devoted the rest of his life. At the outbreak of the great war he abandoned the legal and diplomatic career on which he had embarked, and in his zeal for the faith took service in Poland and afterwards under the Catholic League. He soon became a lieutenant-colonel, and displayed brilliant courage at the battle of the White Hill near Prague (Nov. 8, 1620), where he was left for dead on the field. In the following year he fought against Mansfeld in western Germany.

1 The family of Pappenheim is of great antiquity. In the 12th century they were known as the "marshals of Kalatín (Kalden);” in the 13th they first appear as counts and marshals of Pappenheim, their right to the hereditary marshallship of the empire being confirmed in 1334 by Louis V, in 1334 by the Golden Bull of 1335 they held both marshallship and castle of Pappenheim as fiefs of the Saxon electorate. In the 17th century the family was represented by several lines; those of Pappenheim held the county of Stühlingen till 1685, Treutlingen and Aletzheim, and the older branches (dating from the 13th and 14th centuries) of the marshals of Biberach and of Rechberg-Wertingen-Hohenreichen. Gottfried Heinrich, who belonged to the Treutlingen branch, was the only one of this adherent and his family to attain great distinction, though many other members of it played a strenuous, if subordinate, part in the history of Germany. The family, naturalized under Bavaria in 1806, survives now in the descendants of the Aletzheim branch.
PAPPUS OF ALEXANDRIA

Germany, and in 1623 became colonel of a regiment of cuirassiers, afterwards the famous "Pappenheimers." In the same year, as an ardent friend of Spain, the ally of his sovereign and the champion of his faith, he raised troops for the Italian war and served with the Spaniards in Lombardy and the Grisons. It was his long and heroic defence of the post of Riva on the Lake of Garda which first brought him conspicuously to the front. In 1626 Maximilian of Bavaria, the head of the League, recalled him to Germany and entrusted him with the suppression of a dangerous insurrection which had broken out in Upper Austria. Pappenheim swiftly carried out his task, encountering a most desperate resistance, but always successful; and in a few weeks he had crushed the rebellion with ruthless severity (actions of Efferding, Gmünden, Vöcklabruck and Wolfsegg, 13th-30th November 1626). After this he served with Tilly against King Christian IV. of Denmark, and besieged and took Wolfenbüttel. His hope of obtaining the sovereignty and possessions of the evicted prince was, after a long intrigue, definitely disappointed. In 1628 he was made a count of the empire. The siege and storm of Magdeburg followed, and Pappenheim, like Tilly, has been accused of the most savage cruelty in this transaction. But it is most probable that he merely desired the profitable sovereignty of Magdeburg, and it can hardly be maintained that he deliberately destroyed a prospective source of wealth. At any rate, the sack of Magdeburg was not more indiscriminate than that of most other towns taken by storm in the 17th century. From the military point of view Pappenheim's conduct was excellent; his measures were skilful, and his personal valour, as always, conspicuous. So much could not be said of his tactics at the battle of Breitenfeld, the loss of which was not a little due to the impetuosity of cavalry general, who was never so happy as when leading a great charge of horse. The retreat of the imperialists from the lost field he covered, however, with care and skill, and subsequently he won great glory by his operations on the lower Rhine and the Weser in rear of the victorious army of Gustavus Adolphus. Much-needed reinforcements for the king of Sweden were thus detained in front of Pappenheim's small and newly-raised force in the north. His operations were far-ranging and his restless activity dominated the country from Stade to Cassel, and from Hildesheim to Maastricht. Being now a field marshal in the imperial service, he was recalled to join Wallenstein, and assisted the generalissimo in Saxony against the Swedes; but was again despatched towards Cologne and the lower Rhine. In his absence a great battle became imminent, and Pappenheim was hurriedly recalled. He appeared with his horsemen in the midst of the battle of Lützen (Nov. 6th-16th, 1632). His furious attack was for the moment successful. As Rupert at Marston Moor sought Cromwell as his worthiest opponent, so now Pappenheim sought Gustavus. At about the same time as the king was killed, Pappenheim received a mortal wound in another part of the field. He died on the following day in the Pleisensburg at Leipzig.

See Kriegschriften von bayerischen Offizieren I. II. V. (Munich, 1820); Hess, Gottfried Heinrich Graf zu Pappenheim (Leipzig, 1858); Eddy, Pappus, in The Encyclopaedia Britannica, 11th ed. (Leipzig, 1898); Wittich, in Allgemeine deutsche Biographie, Band 25 (Leipzig, 1887), and works there quoted.

PAPPUS OF ALEXANDRIA. Greek geometer, flourished about the end of the 3rd century A.D. In a period of general stagnation in mathematical studies, he stands out as a remarkable exception. How far he was above his contemporaries, how little appreciated or understood by them, is shown by the absence of references to him in other Greek writers, and by the fact that his work had no effect in arresting the decay of mathematical science. In this respect the fate of Pappus strikingly resembles that of Diophantus. In his Collection, Pappus gives no indication of the date of the authors whose treatises he makes use of, or of the time at which he himself wrote. If we had no other information than that which he derived from his work, we should only know that he was later than Claudius Ptolemy whom he often quotes. Suidas states that he was of the same age as Theon of Alexandria, who wrote commentaries on Ptolemy's great work, the Synthetica mathematica, and flourished in the reign of Theodosius I. (A.D. 379-395). Suidas says that Pappus was writing a commentary upon the same work of Ptolemy. But it would seem incredible that two contemporaries should have at the same time and in the same style composed commentaries upon one and the same work, and yet neither should have been mentioned by the other, whether as friend or opponent. It is more probable that Pappus's commentary was written long before Theon's, but was largely assimilated by the latter, and that Suidas, through failure to disconnect the two commentaries, assigned a like date to both. A different date is given by the marginal notes to a 10th-century MS., where it is stated, in connexion with the reign of Dicetoian (A.D. 284-305), that Pappus wrote during that period; and in the absence of any other testimony it seems best to accept the date indicated by the scholiast.

The great work of Pappus, in eight books and entitled συναγωγή or Collection, we possess only in an incomplete form, the first book being lost, and the rest having suffered considerably. Suidas enumerates other works of Pappus as follows: Χαρακτήρια προς τὴν θεωρίαν τῆς μεγάλης συμμετρίας, ἐπιστημῶν τύπου τῆς καὶ τὴν Αριστοτέλειαν. The question of Pappus's commentary on Ptolemy's work is discussed by Hultsch, Pappi collectio (Berlin, 1878), vol. iii. p. xii. seq. Pappus himself refers to another commentary of his own on the Ανάλυμα of Diodorus, of whom nothing is known. He also wrote commentaries on Euclid's Elements (of which fragments are preserved in Proclus and the Scholia, while that on the tenth Book has been found in an Arabic MS.), and on Ptolemy's Άρμονίκα.

The characteristics of Pappus's Collection are that it contains an account, systematically arranged, of the most important results obtained by his predecessors, and, secondly, notes explanatory of, or extending, previous discoveries. These discoveries form, in fact, a text upon which Pappus enlarges discursively. Very valuable are the systematic introductions to the various books which set forth clearly in outline the contents and the general scope of the subjects to be treated. From these introductions we are able to judge of the style of Pappus, and, while he says little, we may gather that the moment he is free from the shackles of mathematical formulæ and expressions. At the same time, his characteristic exactness makes his collection a most admirable substitute for the texts of the many valuable treatises of earlier mathematicians of which time has deprived us. We proceed to summarize briefly the contents of that portion of the Collection which has survived, mentioning separately certain propositions which seem to be among the most important.

We can only conjecture that the lost book i., as well as book ii., was concerned with arithmetical, book iii. being clearly introduced as beginning a new subject.

The whole of book iv. (the former part of which is lost, the existing fragment beginning in the middle of the 14th proposition) related to a system of multiplication due to Apollonius of Perga. On this subject see Nesselmann, Algebra der Griechen (Berlin, 1842), pp. 125-134; and M. Cantor, Geschichte d. Math. I. 231. The contents contain geometrical problems, plane and solid. It may be divided into five sections: (1) On the famous problem of finding two mean proportions between two given lines, which arose from that of duplicating the cube, reduced by Hippocrates in the fourth book of his Elements, and later on by Apollonius. Pappus gives several solutions of this problem, including a method of making successive approximations to the solution, the significance of which he apparently failed to appreciate: he adds his own solution of the more general problem of finding any side of a cube whose content is in any given ratio to that of a given one. (2) On the arithmetic, geometric and harmonic means between two straight lines, and the problem of representing all three in one and the same geometrical figure. This serves as a basis for the later discussion on geometric series. Pappus distinguishes ten kinds, and gives a table representing examples of each in whole numbers. (3) On a curious problem suggested by Eucl. I. 21. (4) On the inscribing of each of the five regular polyhedra in a sphere. (5) An addition by a later writer on another solution of the first problem of the book.

Of book iv. the title and preface have been lost, so that the programme has to be gathered from the book itself. At the beginning
is the well-known generalization of Eucl. i. 47, then follow various theorems on the circle, leading up to the problem of the construction of a circle which shall circumscribe three given circles, touching each other two and two. This and other several propositions on constructions, touching three, or touching four, etc., are included in the figure made of three semicircles and known as ορθός (shoemaker’s knife) form the first division of the book. Pappus turns then to a consideration of certain properties of Archimedes’ spiral, the construction of which (already mentioned in texts as a sonantic, or a method of doubling the cube), and the curve discovered most probably by Hippasus of Elis about 420 B.C., and known by the name τριγωνοδοτική, or quadratrix. Proposition 30 describes the construction of a quadratrix curvilinear, which we have seen (VI. 16) is the form of a surface; it is described by a point moving uniformly along the arc of a great circle, which itself turns about its diameter uniformly, the point describing a quadrant and the great circle a complete revolution. If the sum of the arcs between this curve and its base is found—the first known instance of a quadrature of a curved surface. The rest of the book treats of the trisection of an angle, and the solution of more general problems of this kind, by means of the quadratrix and spiral. In one solution of the former problem a first record of the sum of the properties of a conic (a hyperbola) with reference to the focus and directrix. In book v., after an interesting preface concerning regular polygons, and containing remarks upon the hexagonal form of the cell walls of honey, Pappus proceeds to treat of the areas of different plane figures which have all the same perimeter (following Zenodorus’s treatise on this subject), and of the volumes of different solid figures which all have the same superficial area. The final proposition in this book is a generalization of this one, that the volumes of two similar cones, rectangular prisms, and cylinders are to each other as the squares of their altitudes. Incidentally Pappus describes the thirteen other polyhedra bounded by equilateral and equiangular but not similar polygons, discovered by Archimedes, and finds, by a method recalling that of Archimedes, the area of a sphere.

According to the preface, book vi. is intended to resolve difficulties occurring in the so-called μεθοδος κατρογωνοδοτικής. It accordingly comments on the Sphaerica of Theodosius, the Moving Sphere of Autolycus, the work of Hipparchus of Tenedos, and the treatise of Aristarchus On the Size and Distances of the Sun and Moon, and Euclid’s Optics and Phaenomena.

The preface of book vii. explains the terms analysis and synthesis, and introduces the treatise. The problem of Euclid is first enumerated works of Euclid, Apollonius, Aristaeus and Eratosthenes, thirty-three books in all, the substance of which he intends to give, with the lemmas necessary for their elucidation. With the name of Euclid the book begins, and in Euclid’s Optics we have an account of the relation of porism to theorem and problem. In the same preface is included (a) the famous problem known by Pappus’s name, often enunciated thus: Having given a number of straight lines, to find the geometric locus of a point such that the lengths of the perpendiculars upon, or (more generally) the lines drawn from it obliquely at given inclinations to, the given lines satisfy the condition that the product of certain of them may bear a constant ratio to the product of the remaining ones, not expressed by formulae but by means of the composition of ratios, saying that if the ratio is given which is compounded of the ratios of pairs—one of one set and one of another—of the lines so drawn, and of the ratio of the odd one, if any, to a given strait line, we shall have the curve required or the points on the theorems which were rediscovered by and named after Paul Guldin, but appear to have been discovered by Pappus himself. Book vii. contains also (1), under the head of the de determinata sectiones, lemmas which, if truthfully examined, are to be cases of the involution of six points; (2) important in Porisms of Euclid (see Porism); (3) a lemma upon the Surface Loci of Euclid which states that the locus of the point such that its distance from a given point bears a constant ratio to its distance from a given straight line is a conic, and is followed by proofs that the parabola, ellipse, or hyperbola according as the constant ratio is equal to, less than or greater than 1 (the first recorded proofs of the properties, which do not appear in Apollonius).

Books viii. and ix. treat of mechanics, the properties of the centre of gravity, and some mechanical powers. Interspersed are some questions of pure geometry. Proposition 14 shows how to draw an ellipse through five given points, and Prop. 15 gives a simple construction for the square root of a number, when a pentagon and dodecagon diameters are given.

Authority.—Of the whole work of Pappus the best edition is that of Hultsch, bearing the title Pappi alexandrinorum collectiones quae supersunt, ex originalibus manuscritis editione, et comm. editoriali praefato. (Berlin, 1875–1876). Previously the entire collection had been published only in a Latin translation, Pappi alexandrinorum mathematicae collectiones a Federico Commandini in duodecim liberis digestae et commentariis instructi (Venice, 1835–1838). The second (1852) edition of this work was published by Carus Manessei.

Books which contain parts of Pappus’s work, or treat incidentally of it, may be mentioned the following titles: (1) Pappi alexandrinorum collectiones mathematicae quae supersunt (reprinted at Venice, 1859, and at Paris, 1862). (2) A secundii edition of this work was published by Carolus Manessei.

Of books which contain parts of Pappus’s work, or treat incidentally of it, we may mention the following titles: (1) Pappi alexandrinorum collectiones mathematicae quae supersunt (reprinted at Venice, 1859, and at Paris, 1862). (2) A book by Dr. A. B. Meyer, who wrote several papers in the Malay Archipelago Journal, gives an account of the Malay Peninsula . . . have little affinity or resemblance to the Papuans.

The constitution of society is everywhere simple. The Huxleys believed that the Papuans were more closely allied to the Negritos of the Philippines and the Semangs of the Malay Peninsula. Alfred Russel Wallace pronounced against this hypothesis in an appendix to his Malay Archipelago Journal, 1853 ed., p. 60, where he observes that the "black, woolly-haired, and bearded Papuans . . . have . . ." and so forth. The same term also appears to refer to the Papuans in the Malay Peninsula . . . have little affinity or resemblance to the Papuans.

Tenevinte Years in Polynesia, pp. 77, 78.
people live in village communities whose members appear to be more or less inter-related. There are no priests and no hereditary chiefs, though among the more advanced tribes a rank is hereditary. To the standard Polynesian system of kinship is added one observed in Torres Strait islands, and also in the Finch and west coasts. Chiefship is quite unrecognized, except on the Keriwina Islands. Possessions, such as gardens, houses, pigs, &c., belong to individuals and not to the community, and pass to the owner's heirs, who differ in relationship in different districts. The land within certain boundaries belongs to the tribe, but a member may take possession of any unappropriated portion. There are certain degrees of relationship within which a man may not marry. In some districts he may not marry into his own village, or into his mother's tribe; in others he may select a wife from certain tribes only. Payment, or a present, is always made for a wife to her father, brother or guardian (who is generally her maternal uncle). Presents are also often made to the bride. Polygamy is practised, but not frequently, and from the wife (or wives) there comes no opposition. The child belongs sometimes to the mother's, sometimes to the father's tribe. The Papuans work steadily, and as a rule, more modest than the Polynesian, is the household drudge, and does the greater part of the outdoor work, but the man assists in clearing new gardens and in digging and planting the soil.

In western New Guinea, according to the Dutch missionaries, there is a vague notion of a universal spirit, practically represented by several malevolent powers, as Manu, the most powerful, who resides in the rivers; Na, a river deity; and Hula, a spirit, who is said to live in the rocks by the sea, to raise storms. As a protection against these the people construct—having first with much ceremony chosen a tree for the purpose—a tall rude image called karwars, each representing a recently deceased ancestor, whose spirit is then invoked to occupy the image and protect them against their enemies and give success to their undertakings. The karwar is about a foot high, with head, arms, and legs, roughly cut from the tree, a sort of Erl-König who carries off children; Fahnik, in the rocks by the sea, who raises storms. As a protection against these the people construct—having first with much ceremony chosen a tree for the purpose—a tall rude image called karwars, each representing a recently deceased ancestor, whose spirit is then invoked to occupy the image and protect them against their enemies and give success to their undertakings. The karwar is about a foot high, with head, arms, and legs, roughly cut from the tree, a sort of Erl-König who carries off children; Fahnik, in the rocks by the sea, who raises storms. The karwars are painted and sometimes decorated with a spear and shield, the female holding a snake. They observe omens, have magicians and rain-makers, and sometimes resort to ordeal to discover a crime. Temples (so called) are found in the nooks of cliffs or behind the larger trees. Statues, carved into figures, and the roof-beams and other prominent points decorated with representations of crocodiles or lizards, coarse human figures, and other grotesque ornamentation; but their use is not clearly understood. They are probably in the nature of talismans, or to ward off evil spirits. of the feet or an evolutionary march—almost invariably goes, but rarely singing. All sorts of jingling sounds also are music to the ear, especially the clattering in time of strings of beans in their dry shells, and so these and other rattles are found attached to the drum, leading to the monotonous and unceasing beat of the stick-guards.

Nearly all Papuan houses are built in Malay fashion on piles, and this not only on the coast but on the hillsides. In the north, the east and south-west of the island immense communal Houses, 500 and 700 ft. in length, with a rounded, boat-shaped roof thatched with palm-branches, and looking inside, when undivided, like dark tunnels. In some districts the natives live together in one of these giant structures, which are divided into compartments.

The foundation of a smaller house is set in a hollow or at the foot of the Astrolabe mountains. As a rule elsewhere each family has its independent dwelling. On the north coast the houses are not built on piles; the walls, of bamboo or palm branches, are very low, and the roof of a wooden hut nearly reaches the ground. A barrier at the entrance keeps out pigs and dogs. A sort of table or bench stands outside, used by the men only, for meals and for the subsequent siesta. In east New Guinea sometimes the houses are two-storied, the lower part being used for stores. The ordinary house is 60 to 70 ft. long with a passage down the centre, and stands on a platform or veranda raised on piles, with the ridge-pole projecting considerably above the gables so that the roof may cover it at each end. Under this is a kind of long canopy, covered with leaves, and this is an ancient custom, and is carried through by the natives when they are on the way, or in the rain, and in this way the house is protected against the rain by the tribes. The interior districts villages are built at a short distance off the shore, as a protection against raids by the inland tribes. The interior villages are frequently situated on hill crests, or on top of steep-faces, and are accessible only by a difficult ascent. In the coastal districts, where the forest is extensive, all round can be had. Where such natural defences are wanting the village is protected by high palisades and by fighting platforms on trees commanding its approaches. The dogos, or tree-houses of the north-east coast, are numerous in New Guinea. On the north-east coast many of the villages are tastefully kept, their whole area being clean swept, nicely saddled, and planted with ornamental shrubs, and have in their centre little square palaces, called the nabai, in which the great man lives. The roof is made of casuarina or human bone. The Papuans are mostly ignorant of iron, but work skillfully with axes of stone or tridacna shell and bone chisels, cutting down trees 20 in. in diameter. Two men working on a long blade or a large mat for a canoe, and the other chopping off the piece across, will soon hollow out a large boat. Every man has a stone axe, each village generally owning a large one. Their knives are of bamboo hardened by fire. In digging they use the resemblance between these dials, but the verbal differences have become great. Several dialects are sometimes found on one island. The following are some broad characteristics of the Papuan languages. Consonants are freely used, some of the consonantal sounds being difficult to represent by Roman characters. Many of the syllables are closed. There does not appear to be any difference between the definite and the indefinite article, except in Fiji. Nouns are divided into two classes, one of which takes the possessive suffix, while the other never takes such a suffix. The principle of this division appears to be a near or remote connexion between the possessor and the thing possessed. Those things which belong to a person are marked by the definite article, and the other by the indefinite.

PAPYRUS, the paper reed, the Cyperus Papyrus of Linnaeus, in ancient times widely cultivated in the Delta of Egypt, where it is used for various purposes, and especially as a writing material. The plant is now extinct in Egypt, but is found in the Upper Nile region and in Abyssinia. Theophrastus (Hist. plant. iv. 10) states that it likewise grew in Syria; and, according to Pliny, it was also a native plant of the Niger and Ephruses. Its Greek title παπύρος, Lat. papyrus, appears to be of Egyptian origin. By Herodotus it is always called βυσσὸς. The first accurate description of the plant is given by Theophrastus, from whom we learn that it grew in shallows of 2 cubits (about 3 ft.) or less, its main root being the thickness of a man's wrist and 10 cubits in length. From this root, which lay horizontally, smaller roots pushed down into the mud, and the stem of the plant sprang up to the height of 4 cubits, being triangular and tapering in form. The tufted head or umble is likened by Pliny to a thyrus.

The various uses to which the papyrus plant was applied are also enumerated by Theophrastus. Of the head nothing could have been made but garments, and writing materials of the gods; but the wood of the root was employed in the manufacture of different utensils as well as for fuel. Of the stem of the plant were made boats, sails, mats, cloth, cords, and, above all, writing materials. Its pith was also a common article of food, and was eaten both cooked and in its natural state. Herodotus, too, notices its consumption as food (ii. 92), and incidentally mentions that it provided the material of which the priests' sandals were made (ii. 37). He likewise refers to the use of hyblus as tow for caulking the seams of ships; and the statement of Theophrastus that King Antigonus made the rigging of his fleet of the same material is illustrated by the ship's cable, στβσσιν, wherewith the doors were fastened when Ulysses slew the suitors in his hall (Odys. xli. 390). That the plant was itself used also as the principal material in the construction of light skiffs suitable for the navigation of the pools and shallows of the Nile, and even possibly of the river itself, is shown by sculptures of the fourth dynasty, in which we see represented building a boat with stems cut from a neighbouring plantation of papyrus (Lepsius, Denkm. ii. 12). It is to boats of this description that the Hebrew gōbre (Josh. 2:23) probably refers in the 'vessels of bulrushes upon the waters' (xvii. 2). If the Hebrew γόμβρα (2) also is to be identified with the Egyptian papyrus, something may be said in favour of the tradition that the bulrushes of which the ark was composed in which the infant Moses was laid were in fact papyrus. But
it seems hardly credible that the Cyperus papyrus could have served for so many uses to which it is said to have been applied, and we may conclude that several plants of the genus Cyperus were comprehended under the head of byblus or papyrus—an opinion which is supported by the words of Strabo, who mentions both inferior and superior qualities. The Cyperus divers is still grown in Egypt, and is used to this day for many of the purposes named by ancient writers.

The widespread use throughout the ancient world of the writing material manufactured from the papyrus plant is attested by early writers, and by documents and sculptures. Papyrus rolls are represented in ancient Egyptian wall-paintings; and extant examples of the rolls themselves are sufficiently numerous. The most ancient Egyptian papyrus now known contains accounts of the reign of King Assa (3580-3556 B.C.). The earliest literary papyrus is that known, from the name of its former owner, as the Frise papyrus, and now preserved at Paris, containing a work composed in the reign of a king of the fifth dynasty, and computed to be itself of the age of upwards of 2,500 years B.C. The papyrus discovered in Egypt have often been found in tombs, and in the hands, or swathed with the bodies, of mummies. The ritual of the dead is most frequently the subject. Besides the ritual and religious rolls, there are the hieratic, civil and literary documents, and the demotic and enchorial papyri, relating generally to sales of property. Coptic papyri mainly contain Biblical or religious texts or monastic deeds. Papyrus was also known to the Assyrians, who called it "the reed of Egypt."

The early use of Papyrus among the Greeks is proved by the reference of Herodotus (v. 58) to its introduction among the Ionian Greeks, who gave it the name of δεκαπαλίδας, "twelve skins," the material to which they had already accustomed in Athens it was doubtless in use for literary as well as for other purposes as early as the 5th century B.C. An inscription relating to the rebuilding of the Erechtheum in 407 B.C. records the purchase of two papyrus rolls, to be used for the fair copy of the rough accounts. The very large number of classical and other Greek papyri, of the Ptolemaic and later periods, which have been recovered in Egypt, are noticed in the article on Palaepgraphy. The rolls found in the ruins of Herculaneum contain generally the less interesting works of writers of the Epicurean school.

Papyrus also made its way into Italy, but at how early a period there is nothing to show. It may be presumed, however, that from the very first it was employed as the vehicle for Roman literature. Under the Empire its use must have been extensive, for not only was it required for the production of books, but it was universally employed for domestic purposes, correspondence and legal documents. So indispensable did it become that it is reported that in the reign of Tiberius, owing to the scarcity and dearness of the material caused by a failure of the Coptic crop, the exportation of the material was doubtless prohibited by law. The papyrus plant should be taken strictly to refer to the process followed in its own time; but, with some differences in detail, the same general method of preparation has doubtless been practiced in time immemorial. His text, however, is so confused, both from obscurity of style and from corruptions in the MSS., that there is much difference of opinion as to the meaning of many words and phrases employed in his narrative, and their application in particular points of time. One important particular, however, affecting the primary construction of the material, there can no longer be any doubt. The old idea that it was made from layers or pellets growing between the rind and a central stalk has been abandoned, as it has been proved that the plant, like other reeds, consists only of a cellular pith within the rind. The stem was in fact cut into longitudinal strips for the purpose of being converted into the writing material, these from the centre of the plant being the broadest and most valuable. The strips (texta, papyrae), which were cut with a sharp knife or some instrument, were laid on a board side by side to the required width, thus forming a layer (scheda), across which another layer of shorter strips was laid at right angles. The two layers were then being papyrus in doing this part of the process—formed a sheet (plaga or net), which was then soaked in water of the Nile. The mention of a particular water has caused trouble to the commentators. Some have supposed that certain chemical properties of the Nile water was possessed as a glue or cement to cause the two layers to adhere; others, with more reason, that glutinous matter contained in the material itself was sold by the action of water, whether from the Nile or any other source; and others again read Papyrus in doing this part of the process—that it was an indication that a paste was added, by which the writing was made easier. The sheet was finally hammered and dried in the sun. Any roughness was levelled by polishing with ivory or a smooth shell. But the material was also subject to other defects, such as moisture turning it yellow, or the fading of the writing. Of the various methods of preparing the sheet for writing, the most common is the use of the mallet; spots or stains; and sponge strips (taeniae), in which the ink would run and spoil the sheet. When such faults occurred, the papyrus must be re-made. To form a roll the several sheets rolled together with the edge with which the papyrus was made, but not more than twenty sheets in a roll (scopus). As, however, there are still extant rolls consisting of more than the prescribed number of sheets, either the reading of vicinae is corrupt, or the number was not constant in all times. The capus seems to have been a standard length of papyrus, as sold by the stationers. The best sheet formed the first or outside sheet of the roll, and the others were joined in order of quality, so that the worst sheets were near the center. The text was transcribed on the other side, not for the purpose of fraudulently selling bad material under cover of the better exterior, but in order that the outside of the roll should be composed of that which would best stand wear and tear. Besides, in case of the entire roll not being filled with the text, the unneeded interior sheets at the end could be better spared, and so might be cut off.

The different kinds of papyrus writing material and their dimensions are also enumerated by Pliny. The best quality, formed from the erectus long-papyrus, of which the name hieratica, but afterwards, in the employ of the emperor Augustus, it was called, after him, Augusta; and the charta Livia, or second quality, was so named in honour of his wife. The hieratica thus descended to the third rank. The first two were 7½, or about 9½ in. in width; the hieratica, 11 digiti or 8 in. Next came the charta amphitheatrica, named after the principal place of its manufacture, the amphitheatres of Alexandria, of 9 digiti or 6¾ in. wide. The charta amphitheatrica, by which, from flattening and other methods was increased in width by an inch, in the factory of a certain Pannus at Rome. The Salatica, which took its name from the city of Sais, and was produced in Augustus, was of the same width, but was cut for the purpose of fraudulently selling bad material under cover of the better exterior, but in order that the outside of the roll should be composed of that which would best stand wear and tear. Besides, in case of the entire roll not being filled with the text, the unneeded interior sheets at the end could be better spared, and so might be cut off. The different kinds of papyrus writing material and their dimensions are also enumerated by Pliny. The best quality, formed from the erectus long-papyrus, of which the name hieratica, but afterwards, in the employ of the emperor Augustus, it was called, after him, Augusta; and the charta Livia, or second quality, was so named in honour of his wife. The hieratica thus descended to the third rank. The first two were 7½, or about 9½ in. in width; the hieratica, 11 digiti or 8 in. Next came the charta amphitheatrica, named after the principal place of its manufacture, the amphitheatres of Alexandria, of 9 digiti or 6¾ in. wide. The charta amphitheatrica, by which, from flattening and other methods was increased in width by an inch, in the factory of a certain Pannus at Rome. The Salatica, which took its name from the city of Sais, and was produced in Augustus, was of the same width, but was cut for the purpose of fraudulently selling bad material under cover of the better exterior, but in order that the outside of the roll should be composed of that which would best stand wear and tear. Besides, in case of the entire roll not being filled with the text, the unneeded interior sheets at the end could be better spared, and so might be cut off.
The charta Claudia was made from a composition of the first and second qualities, the Augustus and the Latin, slitted, layer by layer being cut like a book. The last sheet was increased to nearly a foot in width. The largest of all, however, was the macrocollo, probably of good quality and equal to the hieratic, and a cubit or nearly 18 in. wide. It was used by Cicero (Epp. ad Att. 25-26, 32, 36). The width, generally, proved inconvenient, and the broad sheet was liable to injury by tearing.

An examination of extant papyri has had the result of proving that sheets of large size, measuring about 12 in., were used for a large number of rolls of 10 in., others to 8 in., while the smaller sizes range from 4 to 6 in.

An interesting question arises as to the accuracy of the different measurements given by Pliny. His figures regarding the width of the different kinds of papyrus have given rise to much discussion, but the verdict of the width (or height) of the rolls, as distinguished from their length. It has, however, been observed (that in practice the width of extant rolls does not tally in any satisfactory degree) that Pliny and the Attic writers have for the most part used a larger size, running from 10 in. to 12 in., than that estimated by the thickness of the individual sheets of which the rolls are composed.

The first sheet of a roll was named στορανολλον; the last, βαρχατολλον. Under the Romans, the former bore the name of the comes largitionum, who had control of the manufacture, with the date and name of place. It was the practice to transcribe in the varro's statement, repeated by Pliny, that papyrus was first made in Alexander's time, should probably be taken to mean that its manufacture, which till then had been a government monopoly, was relieved from all restrictions. It is not probable, however, that it was ever manufactured from the native plant anywhere but in Egypt. At Rome there was certainly some kind of industry in papyrus, the charta Fanniana, already referred to, being an instance in illustration. But it seems probable that this industry was confined to the re-making of material imported into Italy, as in the case of the charta Claudia. This second manufacture, however, is thought to have been detrimental to the papyrus, as it would then have been in a dried condition requiring artificial aids, such as a more liberal use of gum or paste, in the process. The more brittle condition of the Latin papyri found at Herculaneum has been ascribed to the evil result of this re-making of the material.

As to cultivation of the plant in Europe, according to Strabo the Romans obtained the papyrus plant from Lake Trasimene and other lakes of Etruria, but this statement is unsupported by any other ancient authority. At a later period, however, a papyrus was cultivated in Sicily, which has been identified by Parlatorie with the Syrian variety (Cyperus cyrillus), far exceeding in height the Egyptian plant, and having a more drooping head. It grew in the east and south of the island, where it was introduced during the Arab occupation. It was seen in the 10th century, by the Arab traveller Ibn-Haukal, in the neighbourhood of Palermo, a stream to which it lent its name. From this paper was made the charta parata. But in the 13th century it began to fail, and in 1519 the drying up of the Papiro caused the extinction of the plant in that district. It is still to be seen at Syracuse, but it was probably transplanted thither at a later time, and reared only as a curiosity, as there is no notice of it to be found previous to 1674.

It is with this Syracusan plant that attempts have been made in modern times to manufacture a writing material similar to ancient papyrus.

Even after the introduction of vellum as the ordinary vehicle for literature papyrus still continued to some extent in use outside Egypt, and was not entirely superseded until a late date. It ceased, however, to be used for books sooner than for documents. In the 5th century St Augustine apologizes for sending a letter written on vellum instead of the more usual substance, papyrus (Ep. xvi.), and Cicero (Varr. xii. 38), writing in the 6th century, indulges in a high-brow panegyric on the plant and its value. Of medieval literary Greek papyri very few relics have survived, but of documents coming down to the 8th and 9th centuries an increasing number is being brought to light among the discoveries in Egypt.

Medieval Latin MSS. on papyrus in book form are still extant in different libraries of Europe, viz.: the Horae of St Avitus, of the 6th century, at Paris; Sermons and Epistles of St Augustine, of the 6th or 7th century, at Paris and Geneva; works of Hilary, of the 6th century, at Vienna; fragments of the Digests, of the 6th century, at Pammersfeld; the Antiquities of Josephus, of the 7th century, at Milan; Isidore, De contemptu mundi, of the 7th century, at St Gall; and the Register of the Church of Ravenna, of the 10th century, at Munich. The employment of this material in Italy for legal purposes is sufficiently illustrated by the large number of documents in 11th century, in which it was at Ravenna in 1567, from the 5th to the 10th century. In the papal chancery it was used at an early date, evidence of its presence there being found in the biography of Gregory I. But of the extant papal deeds there is only one roll, which is preserved in the Register of Adrian I. of the year 788, while the latest appears to be one of 1022. There is evidence to show that in the 10th century papyrus was used, to the exclusion of other materials, in papal deeds. In 1058 a roll of the law was brought to the Synod at Lyon (Gregory of Tours, Hist. Franc. v. 5). Of the Merovingian period there are still extant several papal deeds, the earliest of the year 625, the latest of 692. Under Charlemagne and his successors it was still in use. But the manufacture of papyrus or any of the curiosities that it had entirely ceased, as appears from a note by Eustathius in his commentary on the Odyssey, xxi. 390.

PAR (Lati. par, equal), technically a commercial and banking term. When stocks, shares, &c., are purchasable at the price originally paid for them or at their nominal or face value they are said to be at par. When the purchase price is higher than the face value, they are above par, or at a premium; when below face value, they are below par, or at a discount. Par of exchange is the amount of money in the currency of one country which is equivalent to the same amount in the terms of another, both currencies being of the same metal and of a fixed standard of weight and purity. (See Exchange.)

PARÁ, or GROXO PARÁ, a northern state of Brazil, bounded N. by the three Guianas and the Atlantic, E. by the Atlantic and the states of Maranhão and Goiás, S. by Goiás and Matto Grosso and W. by Amazonas. It is the third largest state of the republic, having an area of 443,922 sq. m.; pop. (1896), 38,445 (1906), 445,586. The state is divided into three sections: the central part of the state, the outlet, or neck, being comparatively narrow and the territory on both sides rising to the level of the ancient plateau that covered this part of the continent. In the north is the Guiana plateau, sometimes called Brazilian Guiana, which is “blanketed” and made semi-arid by the mountain ranges on the Brazil-Guiana frontier. In the south the country rises in forested terraces and is broken by escarpments caused by the erosion of the northern slope of the great central plateau of Brazil. With the exception of the
PARÁ

Guiana highlands, and some grassy plains on the island of Marajó and in some other places, the state is densely forested, and its lowest levels are covered with a network of rivers, lakes and connecting channels.

The rivers of the state may be grouped under three general systems: the Amazon and its tributaries, the Tocantins and its tributaries and the rivers flowing direct to the Atlantic. The Amazon crosses the state in a general E.N.E. direction for about 500 m. Its channels, tributaries, *furos* (arms), *igarapés* (creeks, or literally, "canoe paths"), by-channels and reservoir lakes form an extremely complicated hydrographic system. From the north seven large tributaries are received—the Jamundá (which forms the boundary line with Amazonas), Trombetas, Maecurú, Jaúary, Pará, Jary and Anaucuera—pued. The first is, strictly speaking, a tributary of the Trombetas, though several *furos* connect with the Amazon before its main channel opens into the Trombetas. All these rivers have their sources on the Guiana highlands within the limits of the state, and flow southward to the Amazon over numerous rapids and falls, with comparatively short navigable channels before entering the great river. From the south two great tributaries are received—the Tapajós and Xingu—both having their sources outside the state (see AMAZON). The Paraná estuary, unlike the Tapajós, which flows up into the Amazon, is not popularly described as a mouth of the Amazon. Very little Amazon water passes through it except in times of flood. It is connected with the Amazon by navigable tidal *furos*, in which the current is hardly perceptible. The estuary is about 200 m. long and 5 to 30 m. wide, and receives the waters of a large number of streams, the largest of which is the Guama and its chief tributary, the Capim. A number of small rivers discharge into the Atlantic north and south of the Amazon, the largest of which are the Gurupy, which forms the boundary line with Maranhão, the Araquaya, which drains a large area of the eastern slope of the Guiana highlands, and the Oyapok, which forms the boundary line with French Guiana.

Lying across the mouth of the Amazon and dividing it into three channels are the islands of Caviana and Mexiana, the first 47 m. and the second 27 m. in length, north-west to south-east, both traversed by the equator, and both devoted to cattle-raising. Somewhat different in character is the island of Marajó, or Joanes, which lies between the Amazon and Paraná estuaries. It is about 60 m. long by 90 m. wide, and its area is about 12,000 sq. m. This island is only partly alluvial in character, a considerable area on its eastern and southern sides having the same geological formation as the neighbouring mainland. The larger part, north-western, belongs to the flood-plain of the Amazon, being covered with swamps, forests and open meadows, and subject to annual inundations. There are several towns and villages on the island, and stock-raising, now in a state of decadence, has long been its principal industry. Of interest to archaeologists is the largest of its several lakes, called Arary, in the centre of which is a small island celebrated for its Indian antiquities, chiefly pottery. On the Atlantic coast the principal island is Maracá (lat. 2° N.), 26 m. long by 20 m. wide, which lies, in part, off the entrance to the Amapá river.

Pará is crossed by the equator, and its climate is wholly tropical, but there is a wide variation in temperature and rainfall. In general, it is hot and dry on the Guiana plateau, and hot and humid throughout the forested region. In the latter, there are two recognized seasons, wet and dry, which differ only in the amount of rainfall, a strictly dry season being unconnected with the creation of the wet season, and the reverse. The dry season lasts from about November until March, the height of the dry season being about 10°—28° S., 48°—28° W. The temperature varies from 90°—92° minimum at 73°, and the maximum (2 p.m.) at 89° to 94°. These favourable climatic conditions tend to make the city healthy, but through defective drainage, insanitary habits and surroundings, and improper diet the death-rate is high. The plan of the city is regular and, owing to the density of the forest, it has no outlying suburbs. The streets are usually narrow, straight and well paved. Among the many public squares and gardens the largest are the Praça Caetano Brandão, with a
PARABLE—PARABOLA

statue of the bishop of that name; the Praça da Independência, surrounded by government buildings and having an elaborate monument to General Guirão; the Praça Visconde do Rio Branco, with a statue of José da Gama Melchior; the Praça de Baptist Campo, with artificial cascades, lake, island and winding paths; the Praça da Republica, with a monument representing the Republic; and the Praça de Prudente Moraes, named in honour of the first civilian president of Brazil. Another public outdoor resort is the Bosque, a tract of forest on the outskirts of the city. The public buildings and institutions are in great part relics of an older régime. The great cruciform cathedral, on the Praça Caetano Brandão, dates from the middle of the 18th century. In the vicinity, facing on the Praça da Independência, are the government and municipal palaces—built by order of Pombal (c. 1760), when Portugal contemplated the creation of a great empire on the Amazon. The bishop's palace and episcopal seminary, near the cathedral, were once the Jesuits' college, and the custom-house on the water-front was once the convent and church of the Mercenarios. One of the most notable buildings of the city is the Theatro da Paz (Peace Theatre), which faces upon the Praça da Republica and was built by the government during the second empire. Other noteworthy buildings are: the Cardade hospital, the Mercereidicador hospital (known as the "Santa Casa"), the military barracks occupying another old convent, and the Castello fort, a relic of colonial days. Pará has a number of schools and colleges, public and private, of secondary grade, such as the Ateneo Paranense, Instituto Lauro Sodré and Lyceu Benjamin Constant. There is an exceptionally fine museum (Museu Goeldi), with important collections in ethnography, technology, zoology and botany, drawn from the Amazon valley. The private dwellings are chiefly of the Portuguese one-storey type, with red tile roofs and thick walls of broken stone and mortar, generally plastered outside but sometimes covered with blue and white Lisbon tiles.

Pará is the entrepôt for the Amazon valley and the principal commercial city of northern Brazil. It is the headquarters of the Amazon Navigation Company, which owns a fleet of 40 river steamers, of 500 to 900 tons, and sends them up the Amazon to the Peruvian frontier, and up all the large tributaries where trading settlements have been established. Two or three long-distance lines also have regular calls at this port, and some transatlantic lines afford regular communication with Lisbon, Liverpool, Hamburg and New York. The port is accessible to large steamers, but those of light draft only can lie alongside the quays, the larger being obliged to anchor some distance out. Extensive port improvements have been undertaken. The exports of Pará include rubber, cacao, Brazil nuts and a large number of minor products, such as isinglass, palm fibre, fine woods, tonka beans, deerskins, balsam copaiba, annatto, and other forest products.

Pará was founded in 1615 by Francisco Caldeira de Castello Branco, who commanded a small expedition from Maranhão sent thither to secure possession of the country for Portugal and drive out the Dutch and English traders. The settlement, which he named Nossa Senhora de Belem (Our Lady of Bethlehem), grew to be one of the most turbulent and ungovernable towns of Brazil. Rivalry with Maranhão, the capital of the Amazon dependencies, slave-catching, and bitter controversies with the Jesuits who sought to protect the Indians from this traffic combined to cause agitation. In 1641 it had a population of only 400, but it had four monasteries and a communication office. In 1652 the Pará territory was made a separate capitania, with the town of Pará as the capital, but it was reannexed to Maranhão in 1654. The final separation occurred in 1772, and Pará again became the capital, continuing as such through all the political changes that have since occurred. The bishopric of Pará dates from 1723. The popular movement in Portugal in 1820 in favour of a constitution and parliament (Cortes) had its echo in Pará, where in 1821 the populace and garrison joined in creating a government of their own and in sending a deputation to Lisbon. The declaration of Brazilian independence in 1822 and creation of an empire under Dom Pedro I. was not accepted by Pará, partly because of its influential Portuguese population, and partly because jealousy of Rio de Janeiro as the centre of political power. In 1823 a naval expedition under Lord Cochrane, then in the service of Brazil, took possession of Maranhão, from which place the small brig "Dom Miguel" under the command of Captain John Grenfell was sent to Pará. This officer conveyed the impression that the whole fleet was behind him, and on the 15th of August the junta governativa organized in the preceding year surrendered its authority and Pará became part of the newly created Brazilian empire. An uprising against the new government soon occurred, which resulted in the arrest of the insurgents, the execution of their leaders, and the incarceration of 253 prisoners in the hold of a small vessel, where all but four died from suffocation before morning. Conspiracies and revolts followed, and in 1835 an outbreak of the worse elements, made up chiefly of Indians and half-breeds, occurred, known as the "Revolução da Capanagem," which was chiefly directed against the Portuguese, and then against the Freemasons. All whites were compelled to leave the city and take refuge on neighbouring islands. The Indians and half-breeds obtained the mastery, under the leadership of Antonio and Francisco Vinagres and Eduardo Angelini, and plundered the city and neighbouring towns into a state of anarchy, the population of the city reduced from 25,000 to 15,000. The revolt was over in 1836, but the city did not recover from its effects until 1848. But the opening of the Amazon to foreign trade in 1867 greatly increased the importance of the city, and its growth has gone forward steadily since that event.

(A. J. L.)

PARABLE (Gr. παράβολα, a comparison or similitude), originally the name given by Greek rhetoricians to a literary illustration avowedly introduced as such. In late Greek it came to mean a fictitious narrative or allegory (generally something that might naturally occur) by which moral or spiritual relations are typically set forth, as in the New Testament. The parable differs from the apologue in the inherent probability of the story itself, and in excluding animals or inanimate creatures from passing out of their natural sphere and assuming the powers of man, but it resembles it in the essential qualities of brevity and definiteness, and also in its Eastern origin. There are many beautiful examples of the parable in the Old Testament, that of Nathan, for instance, in 2 Sam. xii. 1-9, that of the woman of Tcoah in 2 Sam. xiv. 1-13, and others in the Prophets.

PARABOLA, a plane curve of the second degree. It may be defined as a section of a right circular cone by a plane parallel to a tangent plane to the cone, or as the locus of a point which moves so that its distances from a fixed point and a fixed line are equal. It is therefore a conic section having its eccentricity equal to unity. The parabola is the curve described by a projectile which moves in a non-resisting medium under the influence of gravity (see Mechanics). The general relations between the parabola, ellipse and hyperbola are treated in the articles GEOMETRY, ANALYTICAL, and CONIC SECTIONS; and various projective properties are demonstrated in the article GEOMETRY, PROJECTIVE. Here only the specific properties of the parabola will be given.

The form of the curve is shown in fig. 1, where P is a point on the curve equidistant from the fixed line AB, known as the directrix, and the fixed point F known as the focus. The line passing through the focus and perpendicular to the directrix is the axis or principal diameter, and meets the curve in the vertex G. The line FL perpendicular to the axis, and passing through the focus, is the semilatus rectum, the latus rectum being the focal chord parallel to the directrix. Any line parallel to the axis is a diameter, and the parameter of any diameter is measured by the focal chord drawn parallel to the tangent at the vertex of the diameter and is equal
PARABOLA

to four times the focal distance of the vertex. To construct the parabola when the focus and directrix are given, draw the axis $CD$ and bisect $CF$ at $A$, which is the vertex. Any number of points on the parabola are obtained by taking any point $E$ on the directrix, joining $EG$ and $EF$ and drawing $FP$ so that the angles $PFE$ and $PDE$ are equal. Then $EG$ produced meets $FP$ in a point on the curve. By joining the points so obtained the parabola may be described. A mechanical construction, when the same conditions are given, consists in taking a rigid bar $ABC$ bent at right angles at $B$ (fig. 2), and fastening a string of length $BC$ to $B$ and $C$. Then if a pencil be placed along $BC$ so as to keep the string taut, and the limb $AB$ be slid along the directrix, the pencil will trace out the parabola.

Properties which may be readily deduced by euclidian methods from the definition include the following: the tangent at any point bisects the angle between the focal distance and the perpendicular on the directrix and is equally inclined to the focal distance and the axis; tangents at the extremities of a focal chord intersect at right angles on the directrix, and as a corollary we have that the locus of the intersection of tangents at right angles is the directrix; the circumcenter of a triangle circumscribing a parabola passes through the focus; the subtangent is equal to twice the abcissa of the point of contact; the subnormal is constant and equals the semilatus rectum; and the radius of curvature at a point $P$ is $2(FF)\alpha a^3$ where $a$ is the semilatus rectum and $FP$ the focal distance of $P$.

A fundamental property of the curve is that the line at infinity is a tangent (see GEOMETRY, PROJECTIVE), and it follows that the centre and the second real focus and directrix are at infinity. It also follows that a line half-way between a point and its polar and parallel to the latter touches the parabola, and therefore the lines joining the middle points of the sides of a triangle circumscribing the parabola passes through the focus; also that the nine-point circle of a self-conjugate triangle passes through the focus. The orthocentre of a triangle circumscribing a parabola is on the directrix; a deduction from this theorem is that the centre of the circumcenter of a self-conjugate triangle is on the directrix ("Steiner's Theorem").

In the article GEOMETRY, ANALYTICAL, it is shown that the general equation of the second degree represents a parabola when the highest terms form a perfect square.

Analytic Geometry.

This is the analytical expression of the projective property that the line at infinity is a tangent. The simplest equation to the parabola is that which is referred to its axis and the tangent at the vertex as the axes of co-ordinates, when it assumes the form $y^2=4ax$ where $a$ is semilatus rectum; this may be deduced directly from the definition. An equation of similar form is obtained when the axes of co-ordinates are any diameter and the tangent at the vertex. The equations to the tangent and normal at the point $x'y'=a(x'-x')$ and $a(y'-y')+(x'-x')=0$, and may be obtained by general methods (see GEOMETRY, ANALYTICAL, and INFINITESIMAL CALCULUS).

More convenient forms in terms of a single parameter are deduced by substituting $x'=am^2$, $y'=2am$ (for on eliminating $m$ between these relations the equation to the parabola is obtained). The tangent then becomes $my=2x+am^2$ and the normal $ym=mx+am^2$. The envelope of this last equation is $272\gamma^2=4(x-2a)$, which shows that the evolute of a parabola is a semi-cubical parabola (see below Higher Orders).

The cartesian equation to a parabola which touches the co-ordinate axes is $\sqrt{ax}+\sqrt{by}=1$, and the polar equation when the focus is the pole and the axis the initial line is $r=\cos \theta=2a$.

The equation to a parabola in triangular co-ordinates is generally derived by expressing the condition that the line at infinity is a tangent in the equation to the general conic. For example, in trilinear co-ordinates, the equation to the general conic circumscribing the triangle of reference is $\rho^2+\mu x+\nu y+\lambda z=0$; for this to be a parabola the line $\alpha x+\beta y+\gamma z=0$ must be a tangent. Expressing this condition we obtain

$$\sqrt{a}=\sqrt{\frac{m}{\beta}}=\sqrt{\frac{\nu}{\gamma}}=0$$ as the relation which must hold between the co-efficients of the above equation and the sides of the triangle to be circumscribed by the conic which represents a parabola. Similarly, the conditions for the inscribed conic $\sqrt{a}+\sqrt{b}+\sqrt{c}=0$ to be a parabola is $hc+b=ma+nb \neq 0$, and the conic for which the triangle of reference is self-conjugate is $x^2+my^2+ny^2=mc$ is $\alpha x^2+\beta y^2+\gamma z^2=0$. The various forms in areal co-ordinates may be derived from the above by substituting $\lambda$, $\mu$, $\nu$ for $m$ and $n$ for $r$, or directly by expressing the condition for tangency of the line $x+y+z=0$ to the conic expressed in areal co-ordinates. In tangential $(p, q, r)$ co-ordinates the inscribed and circumscribed conics take the forms $\lambda p+\mu q+\nu r=0$ and $\lambda x+\mu y+\nu z=0$; these are parabolas when $\lambda x+\mu y+\nu z=0$ respectively.

The length of a parabolic arc can be obtained by the methods of the infinitesimal calculus; the curve is directly quadrable, the area of any portion between two ordinates being two thirds of the circumracting parallelogram. The pedal equation with the focus as origin is $p^2=ar$; the first positive pedal for the vertex is the cissoid (see GEOMETRY, ANALYTICAL) for the focus the directrix. (See INFINITESIMAL CALCULUS)

REFERENCES.—Geometrical constructions of the parabola are to be found in T. H. Eagles' Plane Curves (1873). See bibliography to the articles CONIC SECTIONS; GEOMETRY, ANALYTICAL, and GEOMETRY, PROJECTIVE.

In the geometry of plane curves, the term parabola is often used to denote the curves given by the general equation $ax^2+by^2+cz^2=0$, and it consists of two legs asymptotic to the axis of $x$ and two parabolic legs (fig. 3). The simplest form is $xy^2=ax^2-0$, in this case the serpentine position shown in the figure degenerates into a point of inflexion. Descartes used the curve to solve sextic equations by determining its intersections with a circle; mechanical constructions were given by Descartes (Geometry, lib. 3) and Maclaurin (Organica geometrica).

The cubic parabola (fig. 4) is a cubic curve having the equation $y=ax^2+bx^3+cx+d$. It consists of two parabolic branches tending in opposite directions. John Wallis utilized the intersections of this curve with a right line to solve quartic and septics, and Edmund Halley solved sextic equations with the aid of a circle.

Diverging parabolas are cubic curves given by the equation $y=ax^2+bx^3+cx^4+d$. Newton discussed the five forms which arise from the relations of the roots of the cubic equation. When all the roots are real and unequal the curve consists of a closed oval and a parabolic branch (fig. 5). As the two lesser roots are made more and more equal the oval shrinks in size and ultimately becomes a real conjugate point, and the curve, the equation of which is $x^2+(a-b)x-b$ (in which $a>b$) consists of this point and a bell-like branch resembling the right-hand member of fig. 5. If two roots are equal the curve assumes the form shown in fig. 6, and is known as the nodated parabola. Finally, if all the roots are equal, the equation becomes $y=x^3-a$; this curve is the cuspidal or semi-cubical parabola (fig. 7). This curve, which is sometimes termed the Nollan parabola after William Neil (1637-1679), is the evolute of the ordinary parabola, and is especially interesting as being the first
curve to be rectified. This was accomplished in 1657 by Neil in England, and in 1659 by Heinrich van Halteren in Holland. Newton showed that all the five varieties of the diverging parabolas may be exhibited as plane sections of the solid of revolution of the semicircular parabola. A plane oblique to the axis and passing below the vertex gives the first variety; if it passes through the vertex,

\[ y = ax^2 + bx^3 + cx^4 + dx + e, \]

the second form; if above the vertex and oblique or parallel to the axis, the third form; if below the vertex and touching the surface, the fourth form, and if the plane contains the axis, the fifth form results. (See Curve, and Geometry, Analytical.)

PARACELSUS (c. 1490-1541), the famous German physician of the 16th century, was probably born near Einsiedeln, in the canton Schwyz, in 1490 or 1491 according to some, or 1493 according to others. His father, the natural son of a grandmaster of the Teutonic order, was Wilhelm Bombast von Hohenheim, who had a hard struggle to make a subsistence as a physician. His mother was superintendent of the hospital at Einsiedeln, a post she relinquished upon her marriage. Paracelsus's name was Theophrastus Bombast von Hohenheim; for the names Philippus and Aurelius which are sometimes added good authority is wanting, and the epithet Paracelsus, like some similar compounds, was probably one of his own making, and was meant to denote his superiority to Celsus.

Of the early years of Paracelsus's life hardly anything is known. His father was his first teacher, and took pains to instruct him in all the learning of the time, especially in medicine. Doubtless Paracelsus learned rapidly what was put before him, but he seems at a comparatively early age to have questioned the value of what he was expected to acquire, and to have soon struck out ways for himself. At the age of sixteen he entered the university of Basel, but a few years later abandoned the studies therein pursued. He next went to J. Trithemius, the abbot of Sponheim and afterwards of Würzburg, under whom he prosecuted chemical researches. Trithemius is the reputed author of some obscure tracts on the great elixir, and as there was no other chemistry going Paracelsus would have to devote himself to the reiterated operations so characteristic of the notions of that time. But the confection of the stone of the philosophers was too remote a possibility to gratify the fiery spirit of a youth like Paracelsus, eager to make what he knew, or could learn, at once available for practical medicine. So he left school chemistry as he had forsaken university culture, and started for the mines in Tirol owned by the wealthy family of the Fuggers. The sort of knowledge he got there pleased him much more. There at least he was in contact with reality. The struggle with nature before the precious metals could be made of use impressed upon him more and more the importance of actual personal observation. He saw all the mechanical difficulties that had to be overcome in mining; he learned the nature and succession of rocks, the physical properties of minerals, ores and metals; he got a notion of mineral waters; he was an eyewitness of the accidents which befell the miners, and studied the diseases which attacked them; he had proof that positive knowledge of nature was not to be got in schools and universities, but only by going to nature herself, and to those who were constantly engaged with her. Hence came Paracelsus's peculiar mode of study. He attached no value to mere scholarship; scholastic disputations he utterly ignored and despised—and especially the discussions on medical topics, which turned more upon theories and definitions than upon actual practice. He therefore went wandering over a great part of Europe to learn all that he could. In so doing he was one of the first physicians of modern times to profit by a mode of study which is now reckoned indispensable. The book of nature, he affirmed, is that which the physician must read, and to do so he must walk over the leaves. The humours and passions and diseases of different nations are different, and the physician must go among the nations if he will be master of his art; the more he knows of other nations, the better he will understand his own. And the commentary of his own and succeeding centuries upon these very extreme views is that Paracelsus was no scholar, but an ignorant vagabond. He himself, however, valued his method and his knowledge very differently, and argued that he knew what his predecessors were ignorant of, because he had been taught in no human school, "Whence have I all my secrets, out of what writers and authors? Ask rather how the beasts have learned their arts. If nature can instruct irrational animals, can it not much more men?" In this new school discovered by Paracelsus, and since attended with the happiest results by many others, he remained for about ten years. He had acquired great stores of facts, which it was impossible for him to have reduced to order, but which gave him an unquestionable superiority to his contemporaries. So in 1526 or 1527, on his return to Basel, he was appointed town physician, and shortly afterwards he gave a course of lectures on medicine in the university. Unfortunately for him, the lectures broke away from tradition. They were in German, not Latin; they were expositions of his own experience, of his own views, of his own methods of curing, adapted to the diseases that afflicted the Germans in the year 1527, and they were not commentaries on the text of Galen or Avicenna. They attacked, not only these great authorities, but the German graduates who followed them and disputed about them in 1527. They criticized in no measured terms the current medicine of the time, and exposed the practical ignorance, the pomposity, and the greed of those who practised it.

The truth of Paracelsus's doctrines was apparently confirmed by his success in curing or mitigating diseases for which the regular physicians could do nothing. For about a couple of years his reputation and practice increased to a surprising extent. But at the end of that time people began to recover themselves. Paracelsus had burst upon the schools with such novel views and methods, with such irresistible criticism, that an opposition was at first thwarted, but the sea began to rise. His enemies watched for slips and failures; the physicians maintained that he had no degree, and insisted that he should give proof of his qualifications. Moreover, he had a pharmaceutical system of his own which did not harmonize with the commercial arrangements of the apothecaries, and he not only did not use their drugs like the Galenists, but, in the exercise of his functions as town physician, he urged the authorities to keep a sharp eye on the purity of their wares, upon their knowledge of their art, and upon their transactions with their friends the physicians. The growing jealousy and enmity culminated in a dispute with Canon Cornelius von Lichtenfels, who, having called in Paracelsus after other physicians had given up his case, refused to pay the fee he had promised in the event of cure; and, as the judges, to their discredit, sided with the canon, Paracelsus had no alternative but to tell them his opinion. The great scholar of just fame and great虎 doubt left him on the subject that his friends judged prudent for him to leave Basel at once, as it had been resolved to punish him for the attack on the authorities of which he had been guilty. He departed in such haste that he carried nothing with him, and some chemical apparatus and other property were taken charge of by J. Oporinus (1507-1568), his pupil and amanuensis. He went first to Esslingen, where he remained for a brief period, but had soon to leave from absolute want. Then began his wandering life, the course of which can be traced by the dates of his
PARACHUTE

various writings. He thus visited in succession Colmar, Nuremberg, Appenzell, Zurich, Pfaffers, Augsburg, Villach, Meran, Middelheim and other places, seldom staying a twelvemonth in any of them. In this way he spent some dozen years, till 1541, when he was invited by Archbishop Ernst to settle at Salzburg, under his protection. After his endless toasting about, this seemed a promise and place of repose. It proved, however, to be the complete and final rest that he found, for after a few months he died, on the 24th of September. The cause of his death, like most other details in his history, is uncertain. His enemies asserted that he died in a low tavern in consequence of a drunken debauch of some days' duration. Others maintain that he was thrown down a steep place by some emissaries either of the physicians or of the apothecaries, both of whom he had during his life most grievously harassed. He was buried in the churchyard of St Sebastian, but in 1752 his bones were removed to the porch of the church, and a monument of reddish-white marble was erected to his memory.

The first book by Paracelsus was printed at Augsburg in 1529. It is entitled Practica D. Theophrasti Paracelsi, generalis sapientiae, and forms a small quarto pamphlet of five leaves. Prior to this, in 1526-1527, appeared a programme of the lectures he intended to deliver at Basel, but this can hardly be reckoned a specific work. During his residence at Basel, and thereafter, between 1524 and 1835, there were at least two hundred and thirty-four separate publications according to Mook's enumeration. The first collected edition was made by Johann Huser, which was printed in fourteen folio volumes quarto, and is the best of all the editions. Huser did not employ the early printed copies only, but collected all the manuscripts which he could procure, and used them also in forming his text. The only drawback is that rather than omit anything which Paracelsus may have composed, he has gone to the opposite extreme and included writings with which it is pretty certain Paracelsus had nothing to do. The second collected German edition is in four folio volumes, the Paracelsus edition of the Latin edition was made by Pethenius. It is in eleven volumes quarto, and was completed in 1665. Again, in 1616-1618 appeared a reissue of the folio German edition of 1603, and finally in 1658 appeared the Geneva Latin version, in three volumes folio, edited by Bitsius.

The works were originally composed in Swiss-German, a vigorous speech which Paracelsus wielded with unmistakable power. The Latin versions were made or edited by Adam von Bodenstein, Gerard Dorn, Michael Toxites, and Opinioni, about the middle of the 17th century. A few translations into other languages exist, as of the Chirurgia magna and some other works into French, and English. These are based on the Latin translations into English amount to about a dozen, dating mostly from the middle of the 17th century. The original editions of Paracelsus's works are getting less and less common; even the English versions are rare. There are also a number of modern printed editions, however, there is a bulky literature of an explanatory and controversial character, for which the world is indebted to Paracelsus's followers and enemies. A good deal of it is taken up with a defence of chemistry. Or, they were called, "spagyric" medicines against the attacks of the supporters of the Galenic pharmacopoeia.

The aim of all Paracelsus's writing is to promote the progress of medicine, and he endeavours to put before physicians a grand ideal of their profession. In his attempts he takes the general principles he bases it on as the general relationship which man bears to nature as a whole; he cannot divorce the life of man from that of the universe; he cannot think of disease otherwise than as a phase of it. Galenic method is based on simple general theories of the present state of things; his medical system—if there is such a thing—is an adaptation of his cosmogony. It is this latter which has been the stumbling-block to many past critics, who have taken the animal rights to be the same as the animal rights of the future. Dissatisfied with the Aristotelianism of his time, Paracelsus turned with greater expectation to the Neoplatonism which was reviving. His eagerness to understand anything of importance led him to derive his knowledge from Kabbala, where these mysteries seemed to be explained, and from these unsubstantial materials he constructed, so far as it can be understood, his visionary philosophy. Intervened with it, however, were the general tendencies of philosophy and the wave of the new, powerful rush of medicine and philosophy, and they gave it a direction which he himself could not have foreseen.

Some of his doctrines are alluded to in the article MEDICINE (q.v.), and it would serve no purpose to give even a brief sketch of his views, seeing that their influence has passed entirely away, and that they are of interest only in their place in a general history of medicine and philosophy. Defective, however, as they may have been, and unfounded in fact, his kabbalistic doctrines led him to trace the dependence of the human body upon outer nature for its sustenance and cure. The doctrine of signatures, the supposed connexion of every part of the little world of man with a correspond¬

ing part of the world beyond, was the great inspiration of this suggestion of this doctrine, but the idea carried in its train that of species. This led to the search for these, which were not to be found in the bewildering and untasted mixtures of the Galenic prescriptions. Paracelsus declared that the signs of all species were interwoven by chemical operations, and he thought if plants and minerals could be made to yield their active principles it would surely be better to employ these than the crude and unprepared origins. He was visited by some kind of intuition that the operations in the body were of a chemical character, and that when these operations were formed by the order of the species of the alchemists did. Whether or not he believed in the philosopher's elixir is of very little consequence. If he did, he was like the rest of his age: but he troubled himself very little, if at all, about it. He did believe in the immediate use for therapeutics of the salts and other preparations which his practical skill enabled him to make. Technically he was not a chemist; he did not concern himself either with the composition of his compounds or with an explanation of what occurred in their making. If he could get potent drugs to cure disease he was content, and he worked very hard in an empirical way to make them. That he found out some new compounds is certain; but not one great and marked discovery can be ascribed to him. His most important work, the Art Hermetica, or the promise of the Galenic pharmacopoeia; his indirect and possibly greater services are to be found in his stimulating, the revolutionary stimulus, of his ideas about method, his soundness of judgment, his searching criticism, his man of feigned imagination, of powerful and persistent convictions, of unbated honesty and love of truth, of keen insight into the errors (as he thought them) of his time, of a merciless will to lay bare these errors, and the refinement by which he arrived at the truth in which he believed is a model of methodism. His honest confession, his incisive and epigrammatic criticisms are the marks of his age and the men of his age.

Paraclete (from It. parare, to shield, protect; cf. "parasol," "parapet," and Fr. cloude, a fall), an instrument more or less resembling a large umbrella, by which the resistance it offers to the air enables an aeronaut attached to it to descend safely from a balloon or flying machine in the air. The principle of the parachute is so simple that the idea must have occurred to persons in all ages. Simon de la Loubère (1642-1729), in his History of Stamb (Paris, 1671), tells of a person who frequently diverted the court by the prodigious leaps he used to take, he did believe in the immediate use for therapeutics of the salts and other preparations which his practical skill enabled him to make. Technically he was not a chemist; he did not concern himself either with the composition of his compounds or with an explanation of what occurred in their making. If he could get potent drugs to cure disease he was content, and he worked very hard in an empirical way to make them. That he found out some new compounds is certain; but not one great and marked discovery can be ascribed to him. His honest confession, his incisive and epigrammatic criticisms are the marks of his age and the men of his age.

1757: Sebastian Lenormand practically demonstrated the efficiency of a parachute by descending from the tower of Montpellier observatory; but he merely regarded it as a useful means whereby to escape from fire. To J. P. Blanchard (1753-1809) is due the idea of using it as an adjunct to the balloon. As early as 1758 he had constructed a parachute to which was attached a basket. In this he placed a dog, which descended safely to the ground when the parachute was released from a balloon at a considerable elevation. It is stated that he descended himself from a balloon in a parachute in 1793; but, owing to some defect in its construction he fell too rapidly, and broke his leg. André Jacques Garnerin (1760-1823) was the first person who successfully descended from a balloon in a parachute, and he repeated this experiment so often that he may be said to have first demonstrated the practicability of using the machine, though his elder brother, J. B. O. Garnerin (1766-1840), had already the same idea and after his brother's death he was taken prisoner at Marchiennes, and while in captivity at Bude (Budapest) thought out the means of descending from a balloon by means of a parachute. His first public experiment was made on the 22nd of October 1797. He ascended from the park of Monceau, at Paris, and at the height of about 1 m. he
released the parachute, which was attached to the balloon in place of a car; the balloon, relieved suddenly of such a weight, rose very rapidly till it burst, while the parachute descended very fast, making violent oscillations all the way. Garnerin, however, reached the earth in safety. He repeated his parachute experiment in England on the 21st of September 1802. The parachute was dome-shaped, and bore a resemblance to a large umbrella (fig. 1). The case or dome was made of white canvas, and was 23 ft. in diameter. At the top was a truck or round piece of wood 10 in. in diameter, with a hole in its centre, fastened to the canvas by 32 short pieces of tape. The parachute was suspended from a hoop attached to the netting of the balloon, and below it was placed a cylindrical basket, 4 ft. high and 2 ft. in diameter, which contained the aeronaut. The ascent took place at about six o'clock from North Audley Street, London; and at a height of about (it is believed) 8000 ft. Garnerin separated the parachute from the balloon. For a few seconds his fate seemed certain, as the parachute retained the collapsed state in which it had originally ascended and fell very rapidly. It suddenly, however, expanded, and the rapidity of its descent was at once checked, though oscillations were so violent that the car, which was suspended 20 ft. below, was sometimes on a level with the rest of the apparatus. Some accounts state that these oscillations increased, others that they decreased as the parachute descended; the latter seems the more probable. It came to the ground in a field at the back of St Pancras Church, the descent having occupied rather more than ten minutes. Garnerin was hurt a little by the violence with which the basket containing him struck the earth; but a few cuts and a slight nausea represented all the ill effects of his fall. A few years later, Jordaki Kuparento, a Polish aeronaut, made real use of a parachute. He ascended from Warsaw on the 24th of July 1828, in a fire-balloon, which, at a considerable elevation, took fire; but he was able to effect his descent in safety by means of his parachute.

The next experiment made with a parachute resulted in the death of Robert Cocking, who was early as 1814 had become interested in the subject. The great defect of Garnerin’s umbrella-shaped parachute had been its violent oscillation during descent, and Cocking considered that if the parachute were made of a conical form (vertex downwards) the whole of this oscillation would be avoided; and if it were made of sufficient size there would be resistance enough to check too rapid a descent. He therefore constructed a parachute on this principle (fig. 2), the radius of which at its widest part was about 17 ft. It was stated in the public announcements previous to the experiment that the whole weighed 223 lb.; but from the evidence at the inquest it appeared that the weight must have been over 400 lb. exclusive of Cocking’s weight, which was 177 lb. On the 24th of July 1837, the Nassau balloon, with Charles Green, the aeronaut, and Edward Spencer, a solicitor, in the car, and having suspended below it the parachute, in the car of which was Cocking, rose from Vauxhall Gardens, London, at twenty-five minutes to eight in the evening. A good deal of difficulty was experienced in rising to a suitable height, partly in consequence of the resistance to the air offered by the expanded parachute, and partly owing to its weight. Cocking wished the height to be 8000 ft.; but when the balloon reached the height of 5000 ft., nearly over Greenwich, Green called out to Cocking that he should be unable to ascend to the requisite height if the parachute was to descend in daylight. Cocking accordingly let slip the catch which was to liberate him from the balloon. The parachute for a few seconds descended very rapidly, but still evenly, until suddenly the upper rim seemed to give way and the whole apparatus collapsed (taking a form resembling an umbrella turned inside out, and nearly closed), and the machine descended with great rapidity, oscillating very much. When about 200 or 300 ft. from the ground the basket became disengaged from the remnant of the parachute, and Cocking was found in a field at Lee, literally dashed to pieces.

Many objections were made to the form of Cocking’s parachute; but there is little doubt that had it been constructed of sufficient strength, and perhaps of somewhat larger size, it would have answered its purpose. John Wise (1808–1879), the American aeronaut, made some experiments on parachutes of both forms (Garnerin’s and Cocking’s), and found that the latter always were much more steady, descending generally in a spiral curve. A descending balloon half-full of gas either does rise, or can with a little management be made to rise, to the top of the netting and take the form of a parachute, thus materially lessening the rapidity of descent. Wise, in fact, having noticed this, once purposely exploded his balloon when at a considerable altitude, and the resistance offered to the air by the envelope of the balloon was sufficient to enable him to reach the ground without injury. In more recent times the use of the parachute has become fairly common, but a good many serious accidents have occurred.

**PARADE** (Fr. parade; ital. **parata**: cf. Sp. **parada**, from Lat. **parare**). See **promenade**, **envelope**, **aeronaut**. A show, a military gathering of troops for a specific purpose, an assembly of people for a promenade, the place where the troops assemble, and a road or street where people may walk. In the military sense, a “parade” is a mustering of troops on the parade-ground for drill, for inspection, for the delivery of special orders, or for other purposes, either at regular stated hours or on special occasions.

**PARADISE** (Gr. **παραδείσος**), the name of a supernatural locality reserved for God and for chosen men, which occurs in the Greek Bible, both for the earthly “garden” of Eden (see Eden), and for the heavenly “garden,” where true Israelites after death see the face of God (4 Esdras viii. 52; Luke xxiii. 43; 2 Cor. xii. 4; Rev. ii. 7). The Hebrew **parades** (פַּרְדָּא), to which **παραδείσος** corresponds, occurs thrice in the Old Testament in late books, in the general sense of “park, grove”; it is derived somewhat hazily from the Zend **pairi-daena**, an enclosure. The meaning of the word in the Old Testament is not very clear, and is in the account of the mythical enclosure of Vima (see DYLE). But what interests us most is not the name, but the concep­tion and its imaginative vehicle. The conception is the original godliness of human nature, and the necessity of expecting a closer union between God and man in the future than is possible at present. The imaginative form which this conception takes is that before the present condition arose man dwelt near to God in God’s own mountain home, and that when the mischief wrought by “the serpent” has been undone, man—or more strictly the true Israel—shall once more be admitted to his old privilege. According to the fullest Old Testament account (Ezek. xxviii. 12–19; see Adam), the holy mountain was in a definite earthly region, and certainly it was appropriate for worshippers of Yahweh that it should be so (1 Kings xx. 23, 28). But there are traces in that account itself as well as in Gen. ii. that an earlier belief placed the divine
PARADOS—PARAFFIN

home in heaven. Similarly the Zoroastrians speak of their Paradise-mountain Alburz both as heavenly and as earthly (Bundish, xx. 1, with West’s note). It appears that originally this Paradise-mountain was placed in heaven, but that afterwards it was transferred to earth. It was of stupendous size; indeed, properly it was the earth itself. Later on each Semitic people may have chosen its own mountain, recognizing, however, perhaps, that in primateval times it was of vaster dimensions than at present, just as the Jews believed that in the next age the “mountain of Yahweh’s house” would become far larger (Isa. ii. 2 = Mic. iv. 1; Ezek. xii. 2; Zech. xiv. 10; Rev. xxi. 10); compare the idealization of the earthly Alburz of the Iranians “in revelation” (Bund. v. 3, vii. 2, xii. 1-8).

We now return to the accounts in Ezek. xxviii. and Gen. ii. The references in the former to the precious stones and to the “stones of fire” may be grouped with the references in Enoch (xviii. 6-8, xxiv.) to seven supernatural mountains each composed of a different beautiful stone, and with the throne of God on the seventh. These mountains are to be connected with the seven planets, each of which was symbolized by a different metal, or at least colour. Etskiel’s mountain therefore has come to be symbolized by gold, even as the higher stars. We group the four rivers of Paradise inGen. ii. with the phrase so often applied to Canaan, “flowing with milk and honey” (Exod. iii. 8; Num. xiii. 27, &c.). For this descriptive phrase is evidently mythical, and refers to the belief in the four rivers of the heavenly Paradise which “poured honey and milk, oil and wine” (Slavonic Enoch, viii. 5; cf. Vision of Paul, xxiii.). In fact, the four rivers originally flowed in heavenly soil, and only when the mountain of Elohim was transferred to the lower earth could mythological geographic thinkers determine their earthly course, and whether Havilah, or Cush, or Canaan, or Babylonia, was irrigated by one or another of them. In what happened to Paradise when the afflicted human pair left it? One view (see Eth. Enoch, xxxii. 2, 3, 8, lxvii. 3, 4, &c.) was that its site was in some nameless, inaccessible region, still guarded by the “serpents and the cherubim” (Eth. Enoch, xx. 7), and that in the next age its gates would be opened, and the threatening sword (Gen. iii. 24) put away by the Messianic priest-king (Testaments of the Twelve Patriarchs, Levi, 18). This agrees with the story in Gen. ii., iii., except that the original narrator knew the site of the garden. It is a sufficiently reasonable view, for if Paradise lay in some definite earthly region, and if no one knows “the paths of Paradise” (4 Esdras iv. 7), it would seem that it must have ceased to exist visibly. This idea appears to be implied by those Jewish writers, who, especially after the fall of Jerusalem (A.D. 70), dwelt so much on the hope of the heavenly Paradise, reviving, partly under emotional pressure and partly as the result of a fresh influx of mythology, the old myth of a celestial garden of God. To notice only a few leading passages. In Apoc. Bar. iv. 3 it appears to be stated that when Adam transgressed, the vision of the city of God and the possession of Paradise were removed from him, and similarly the stress laid in 4 Esdras iv. 7, vi. 2, vii. (36), 53, viii. 52, on the heavenly Paradise seems to show that no earthly one was supposed to exist. Beautiful, indeed, is the utter simplicity of belief in these passages, with which we may group Rev. xxi. 1, xxi. 5, whereas as in 4 Esdras viii. 52, Paradise and the city of God are combined. Some strange disclosures on this subject are made by the Slavonic Enoch (cf. v.; cf. xxxii. 3), according to which there are two Paradieses. The former is in the third heaven, which explains the well-known saying of St Paul in 2 Cor. xii. 2, 4;[1]

1 It was the Babylonian “mountain of the lands,” which meant not only mother earth, but the earth imagined to exist within the heaven; cf. Jeremias, 1100, pp. 11, 12, 28, and Jastrow, Religion of Bab. and Ass. p. 558. &c. &c.

3 Also 1 Esdras i. 19. This explains Joel iv. 18; Isa. i. 1 (wine and milk). See also Isa., xxi., xii. (Zendavesta); and cf. Cheyne, Ency. Bib., col. 2104, and especially Euser, Rheinische Museum, lxxvi. 177-192.

4 The statement in Gen. iii. 24 comes from a form of the story in which the “garden” was not geographically localized.

the latter is conventionally called the Paradise of Eden. In fact, the belief in an earthly Paradise never wholly died. Medieval writers revived it. The mountain of Purgatory in Dante’s poem is “crowned by the delicious shades of the terrestrial Paradise.”

See further The Apocalypse of Baruch and The Ethiopic and the Slavonic Enoch, both edited by R. H. Charles; also Kautzsch’s Apocrypha, and Voll, Judische Eschatologie (1903), pp. 374-8, whose full references are most useful. On the Biblical references, cf. Gunkel, Genesis (2), pp. 21-35; Cheyne, Ency. Bib., "Paradise"; and on Babylonian views, Jeremias, "Hölle und Paradies" (in Der alle Orient). The Mahommedan’s Paradise is a sensuous transformation of the Jewish; see especially Koran, Surah iv., and note that the "garden of Firdaus," Koran, xviii. 7. For the Zoroastrian accounts see the Sacred Books of the East (Oxford Series). The doorkeeper of the mountain-Paradise of the Parsees is the Amsdsah Apram (Vendidad, xix. 31). (T. K. C.)

PARADOX (Fr. = back cover), a term used in fortification, expressing a work the purpose of which is to cover the defenders of a line of trenches or parapet from reverse fire, i.e. fire from the rear.

PARADOX (Gr. ἀπαράξ, beyond, contrary to, διότι, opinion), a proposition or statement which appears to be at variance with generally accepted doctrine, or which apparently is self-contradictory, absurd or untrue, but either contains a concealed truth or may on examination be proved to be true. A "paradox" has been compared with a "paralogism" (rabā, λόγος, reason), as that which is contrary to opinion only and not contrary to reason, but it is frequently used in the sense of that which is really absurd or untrue.

PARAFFIN, the name given to a mineral wax and oil, and also used as a generic name of a particular series of hydrocarbons.

Commercial Paraffin.—Refined commercial paraffin is a white or bluish-white, translucent, waxy solid substance, of lamino-crystalline structure, devoid of taste and smell, and characterized by chemical indiffERENCE. It consists of about 85% of carbon and 15% of hydrogen. Although the credit of having first (in 1830) investigated the properties of solid paraffin, obtained from wood-tar, belongs to Karl Reichenbach, the existence of paraffin in petroleum had been more or less hitherto little known for some time previous. In 1809 Fuchs found solid hydrocarbons in the Tegersee oils, and in 1819 Buchner separated them from these oils in comparative purity. By the latter they were described as “mountain-fats,” and they were identified with paraffin in 1835 by von Kobel. Reichenbach described the results of a series of experiments on the reactions between various substances and paraffin, and on account of the inert nature of the material gave to it its present name (from the Lat. parum, too little, and affinitas, affinity); he expressly stated that the accent should fall on the second "a," but usage has transferred it to the first.

Paraffin was obtained by Laurent in 1830 by the distillation of bituminous schist, and in 1835 by Dumas from coal-tar; but the product appears to have been regarded only as a curiosity, and Lord Playfair has stated that prior to 1850 he never saw a piece of more than one ounce in weight. Paraffin is asserted to have been made for sale by Reichenbach’s process from wood-tar by John Thom, of Birkacre, before 1835. In 1833 a report suggested the working of the Autumn shale, and products manufactured from this material were exhibited by Sellige in 1839.

According to F. H. Storer, the credit of having first placed the manufacture of paraffin on a commercial basis is deservedly given to Sellige, whose patent specifications, both in France and England, sufficiently clearly show that his processes of distilling bituminous schist, &c., and of purifying the distillate, had reached considerable perfection prior to 1845. In its present form, however, the paraffin or shale-oil industry owes its existence to Dr James Young. In 1850 he applied for his celebrated patent (No. 13,292) "for obtaining paraffine oil, or an oil containing paraffine, and paraffine from bituminous coals" by slow distillation. The process was extensively carried out in the United States under licence from Young,
until crude petroleum was produced in that country in such abundance, and at so low a cost, that the distillation of bituminous minerals became unprofitable. The highly bituminous Boghead coal, or Torbanehill mineral, which yielded 12 to 150 gallons of crude oil per ton, was worked out in 1862, and since then the Scottish mineral oils and paraffin have been obtained from the bituminous shales of the coal-measures, the amount of such shale raised in Great Britain in 1907 being 2,609,028 tons. The following list represents an attempt to assign a geological age to the various occurrences of oil-shale and similar substances throughout the world:

Oil-Shale.—The oil-shale of Scotland is dark grey or black, and has a laminated or non-laminated fracture. Its specific gravity is about 1.75, and 40 cu. ft. of it weighs rather less than a ton. The richer kinds yield about 30 gallons of oil per ton of shale, and in some cases as much as 40 gallons. The higher yield is usually obtained at the expense of the solid paraffin and of the quality of the heavy oils. The inferior shales yield about 18 gallons of oil, but a much larger amount of sulphate of ammonia. The oil consists chiefly of members of the paraffin and olefine series, and differs essentially from that obtained from true coal-shales, in which the hydrocarbons of the benzene group are largely represented.

A full account of the Scotch shaleoil industry, as the most important and typical, will be given later, the corresponding industries in other countries and districts being dealt with first.

In addition to the Carboniferous oil-shales of Flint and Stafford, the Kinneridge shale, a bluish-grey silt clay, containing thin beds of highly bituminous shale, occurs in Dorsetshire, and has from time to time attracted attention as a possible source of shale-oil products. The so-called "Kerosene-shale" of New South Wales has been extensively mined, and the industry is now being developed by the Commonwealth Oil Corporation, Ltd. The French shale-oil industry is much older than that of Scotland, but has made far less progress, the amount of shale distilled in 1897 being 200,000 tons, as compared with 2,250,000 tons in Scotland. The shales of New Zealand have never been extensively worked, the production having decreased instead of increased. Oil-shale of good quality occurs in Servia, and has been found to yield from 43½ to 54½ gallons of oil per ton. The production of mineral oils and paraffin by the distillation of lignite is carried on in the U.S.A., where the mineral worked being a peculiar earthy lignite, occurring within a small portion of the Saxon-Thuringian brown-coal formation. Other occurrences of this mineral have been indicated in the list of localities above.

The Shale-Oil Industry of Scotland.—The modern development of the shale-oil industry of Scotland dates from the commencement of Robert Bell's works at Broxburn in 1862.

The oil-shales are found in the Calcareous Sandstone series, lying between the Carboniferous Limestone and the Old Red Sandstone. They occur at several points in the belt of Carboniferous rocks across the centre of Scotland, for the most part in small syndenial basins, the largest of which is that at Pentland, where the levels are 2 m. long, without important faults. Mining is carried on, where the seams are over 4 ft. thick, by the "pillar and stall" system; seams under 4 ft. are worked by the "longwall" system. The shale is blasted down by gunpowder, and passed over a i-in. riddle, the smalls being left underground. Before being retorted the shale is passed through a toothed breaker, which reduces it to flat pieces 6 in. square. These fall into a shoot, and thence into iron tubs of 10 to 25 cwt. capacity, which run on rails to the tops of the retorts.

The retorts in which the shale is distilled have undergone considerable variation and improvement since the foundation of the industry. Originally horizontal retorts, like those used in the manufacture of coal-gas, were employed, and the heavy oils and paraffin were burned as fuel. When the latter product became valuable vertical retorts were adopted, as the solid hydrocarbons undergo less dissociation under these conditions.

Steam was employed to carry the oil vapours from the retort. The earliest form of vertical retort was circular (2 ft. in diameter) or oval (2 ft. by 1 ft. 4 in.) and 8 or 10 ft. long. Six or eight of these were grouped together, and the heating was so effectuated that the bottoms of the retorts were at the highest temperature. They were charged by means of hoppers at the top, the exhausted shale being withdrawn through a water-seal every hour and fresh added, whence this is known as the "continuous system."

In the first Henderson retort (1873) the spent shale was used as fuel. The retorts, which were oblong in cross-section, were arranged in groups of four, and had a capacity of 18 cwt. They were charged in rotation, as follows: when a sufficient temperature had been attained in the chamber containing them, one retort was charged from the top, and in four hours the one diagonally opposite to it was charged. After eight hours the one next to the first was charged, and after twelve hours the fourth. Up to the sixteenth hour only ordinary fuel was used in the furnace, but the spent shale from the first retort was then discharged into it. The other retorts were similarly discharged in the above order at intervals of four hours, each being at different stages of discharge. After the tank was charged with distilled shale, the amount of carbon from the spent shale, only a slow draught was kept up. The outfall for the oil vapours was at the lower and less heated end of the retorts, and steam, which had been superheated by passage through pipes arranged along one side of the retort chamber, was blown in copiously through pipes to aid in the uniform heating of the shale and to continuously remove the oil vapours, dissociation from overheating being thus minimized. It was believed that a temperature of about 800°F. produced the best results. This retort was worked on what is known as the "interrupted system."

The Pentland Composite retort (1882) and the later Henderson type (1889) were both continuous-working and gas-heated, the second being a modification of the first, designed with a view to obtaining a larger yield of sulphate of ammonia without detritus to the crude oil. In the upper part of the retort was cast iron and the lower of fire-clay. The upper portion was heated to a temperature of about 900°F. whilst the lower was maintained at about 1300°F. The charge in the retort gradually travelled down, owing to the periodical removal of spent shale at the bottom, and the descent was so regulated that no shale passed into the highly-heated part until it had parted with the oil it was capable of yielding. The shale, however, still contained nitrogen, which in the presence of steam produced ammonia at the higher temperature.

The three classes of retorts now employed in the distillation of shale in the Scottish oil-works are covered by the following patents:—
1. Paraffin by the Dry Process, Patented to Robert Bell at Broxburn—No. 8371 of 1894; No. 7113 of 1895; No. 4240 of 1897.
2. In use by Young's Paraffin Light and Mineral Oil Company, Ltd.—No. 13,665 of 1897; No. 15,258 of 1899.
3. In use by the Broxburn Oil Company, Ltd.—No. 26,647 of 1901.

The objects of the invention for which patent No. 8371 of 1894 was granted to Bryson (of Pumphreng Oil Works), Jones (of Dalmeny Oil Works), and Fraser (of Pumphreng Oil Company, Ltd.), are described in the specification as "so to construct the retorts and provide them with means whereby fluxing or dandering of the substance being heated is prevented in the retorts: also to effect an intermittent, continuous, or nearly so, movement within the retort." In order to carry out these objects, the bottom of the
PARAFFIN

PARAFFIN residue in working lower device bottoms temperature in hopper, shale; invention of all, being instituted the wards, swept 754

The burn the continuous means retorts granted Fyfe he heated for labour, and heat and admitting the of the retorts, end provided this. In this regularity, with the carbon of shale, which is provided for recycling, the shale being discharged from the retort as possible, thus utilizing all, or nearly all, the heat contained in the waste material in the retort, thus saving labour, time and expense, as well as wear and tear of the retorts.

The object of the invention for which patent No. 4249 of 1897 was granted to Bryson is stated to be “to so construct the hoppers of the retorts that one or more retorts can be drawn or discharged through the hopper, to provide simple and efficient means for operating the said door.”

Patent No. 13,665 of 1897 was granted to William Young and John Fyfe for an invention the objects of which are described in the specification, in the following terms: retorts, save fuel, and increase the products, and to enable existing built out retorts that have been erected in accordance with the above invention to be economically replaced upon existing foundations by similar retorts, provided with improved and enlarged multiple hopper systems, for the reception of the shale to pass through the hopper, and also enlarged chambers for the reception of the ash or exhausted shale; the retorts being provided with mechanical arrangements for the continuous passage of the fresh shale into them from the multiple hopper systems, the provision of which is continuous with the hoppers or of the receiving chamber. Those improved mechanical alterations in the structure of the retorts greatly reduce the manual labour, enabling most of the work to be done during the day, the multiple hoppers and toothed chamber and the toothed sliding of the supply fresh shale and receive the spent shale during the night-shift, the only labour then required being the supervision, regulating temperature of the retorts, and seeing that the mechanical arrangements are working properly.

The multiple hoppers are constructed of mild steel plates with flat bottoms to which the retorts are bolted by flanges, the steel bottoms admitting of the differential expansion, to which the retorts are secured without the necessity of the retorts being unbolted.

To ensure the shale regularly passing from the hoppers to the retorts, each hopper is provided with a rocking-shaft to which are attached rods or chains hanging into the mouths of the retorts, these rods or chains being used to raise or lower the shale. The toothed chambers at the lower end of each retort are of greatly enlarged size, and the lower end of each retort is provided with a mechanical device for the continuous discharge of the spent shale into these chambers, or that is applicable to retorts of the Young and Beilby (Pentland) type.

Patent No. 15,238 of 1899 was obtained by the same inventors for improvements in obviating objections found to attach to retorts constructed on the ordinary Young and Beilby system. In the use of such retorts, composed of an upper metallic section and a lower fire-brick section, with chambers or hoppers at their upper ends, these upper ends became gradually filled up with hard carbonaceous material, preventing the retorts from working to have such matter removed. Moreover, the shale residues became fixed and flashed to the walls of the lower section of the retorts. The residues were further liable to pass through the retort in an unsatisfactory condition, and results were obtained which affected the economy of the retorts and the yield of the shale. There was also found that when air and steam were used in imitation of the quantities and proportions of steam and air used in the process, the results obtained were unsatisfactory due to the smaller amount of air used and the obstructions due to flushing of the residues. To overcome these drawbacks each retort is composed of four sections, viz. a hopper redistillation chamber at the top, a metallic section, a fire-brick chamber, and a combustion chamber of large capacity at the bottom. The chamber is not externally heated, but receives the internal heat of the retort or the reformed gases from the retort, or the two, in such proportions that the air and steam are utilized for the distillation of the shale residue. The operation of the retort is such that the residue is heated to a high temperature, the char being burnt to carbon, and the carbon remaining in the residue is burnt to carbon dioxide by the oxygen of the air. The carbon dioxide is absorbed by the water in the air, and the water is distilled out, the residue being reduced to a mixture of carbon and metal, the carbon being burnt to carbon dioxide by the oxygen of the air. The carbon dioxide is absorbed by the water in the air, and the water is distilled out, the residue being reduced to a mixture of carbon and metal, the carbon being burnt to carbon dioxide by the oxygen of the air.

The vapour from these retorts, amounting to about 3000 cu. ft. per ton, is partially condensed by being passed through 70 to 100 vertical 4-in. pipes, whose lower ends fill a chest. About one-third of the vapour is condensed, the liquid, consisting of about 75% of ammoniacal liquor and 25% of crude oil, flowing into a separating tank, whence the two products are separately withdrawn for further treatment. Part of the uncondensed gas is sometimes purified and used for illuminating purposes, when it gives a light of about 25 candlepower. The remainder is used as fuel, usually after compression of the oil, in order to remove condensable vapours.

Crude shale-oil is of dark greenish black, and has a specific gravity of 0.86 to 0.89, and at present manufactured, with the newer forms of retorts, has a setting point of about 0° F. It contains from 50 to 50% of members of the paraffin and olefine series, together with bases of the pyrene series, and some cresols and phenols. Beilby states that average Scotch shale-oil contains from 1:16 to 1:45% of nitrogen, mainly removable by sulphuric acid of specific gravity 1:32, and mostly remaining in the pitchy residues left on distillation. The lightest distillate, known as naphtha, contains from 60 to 70% of olefines and other hydrocarbons acted upon by fuming nitric acid, and the lubricating oils consist mainly of olefines. The paraffin wax chiefly distils over with the oil of specific gravity above 0.840.

In the refining of crude shale-oil, the greatest care is exercised to prevent dissociation of the paraffin, large volumes of superheated steam being passed into the still, through a perforated pipe, at a pressure of from 0 to 10 lb, to facilitate distillation at the lowest possible temperature. The general system of intermittent distillation is now employed only at the works of Young's Company. The stills have cast-iron bottoms and malleable-iron upper parts, their former capacity being 1200 to 1400 gallons, but those now made usually hold between 2000 and 2500 gallons. Each still has its own water-condenser, the flow of water being regulated according to the nature of the distillate. The usual condensing surface is 230 ft. of 4-in. pipe. The process now in general practice is, with slight variations, the Henderson system of continuous distillation (patent No. 13,014 of 1883). It consists of a primary wagon-still, connected with two side-stills, which are further connected with pot-shaped koking-stills. The oil is heated in feed-heaters by the gases evolved from the hottest still before passing into the first still, where the temperature is reduced to 400° F. in agitators of varying construction—some being horizontal cylinders with a shaft carrying paddles, while others take the form of vertical cylindrical tanks with egg-shaped bottoms—in which agitation is produced by means of compressed air. The loss of oil during the agitation is estimated at 1:5 to 2.0%.

The oil is next fractionated, either by the intermittent or the continuous system. After the most volatile fractions have distilled off, steam is blown through a pipe at the bottom of the still. In many cases the distillate, with a density up to
o.770, constitutes the crude naphtha, and that up to a density of 0.850 the burning oil. The remainder of the distillate, which solidifies at common temperatures, consists chiefly of lubricating oils and paraffin. These three fractions are delivered from the condensers into separate tanks. Although the crude oil stills of Henderson may be employed for the continuous distillation of the once-run or other oils obtained in the process of refining, the inventor prefers another form of apparatus which he patented in 1883 (No. 540), and this is now generally used. This consists of three horizontal cylindrical stills, 7 ft. in diameter and 19 ft. in length. The oil enters through a pipe which passes through one end of the still and discharges at the opposite end, while the outlet-pipe is fitted below the inlet-pipe at the bottom of the end through which the latter passes, inlet and discharge being thus as far as possible from each other. The oil circulates as in the crude-oil stills. The burning oil is next treated with acid and alkali, and subsequently again fractionally distilled, the heavier portion yielding paraffin scale, while the residues are redistilled. The final chemical purification of the burning oil resembles that last referred to, but only half the quantity of acid is employed. The lighter products of these distillations form the crude naphtha still, which is treated with acid and alkali, and redistilled, when the lighter fractions constitute the Scotch "gallstones" of commerce, and the remainder is known as "naphtha."

The solid paraffin, which is known in its crude state as paraffin scale, was formerly produced from the heavy oil obtained in the first, second and third distillations, that from the first giving "hard scale," while those from the second and third gave "soft scale." The hard scale was crystallized out in shallow tanks, and the contained oil driven out by compression of the paraffin in filter bags. Soft scale was obtained by refrigeration, cooled revolving drums being caused to dip into trays containing the oil, when the paraffin adhered to the drums and was scraped off by a mechanical contrivance. Later improved appliances have been arranged at the latter; and large cylindrical latticeworks of paraffin are produced. Several processes have been invented, the most generally used being that patented by Henderson (No. 9572 of 1884). His cooler consists of a jacketed trough having a curved bottom, and divided into a series of transverse casings by metal disks, each consisting of two thin plates bolted together, but with a space between, in which, as also in the jacket surrounding the trough, cold brine is circulated. The paraffin crystallizes on the cold surfaces, from which it is constantly removed by scrapers, so that successive portions of the oil are cooled. The solid paraffin accumulates in a well or channel, where it is stirred up by rotary arms, so that it may be readily drawn away by a pump to the filter-pressure, whereby the solid paraffin is freed from oil. In the improved process of cooling employed at the works of the Oakbank Oil Company the oil to be cooled is pumped through coils submerged in the expressed oil from the filter-pressure into the inner portion of vertical coolers formed of two cast-iron tubes, and thence direct to the filter-presses. In the inner chamber of the coolers are fitted revolving scrapers, while in the outer annular space compressed ammonia is expanded.

The crude paraffin is then refined, for which purpose the "naphtha treatment" was formerly employed, but this has now given place almost entirely to the "swearing process." In the former the paraffin is dissolved in naphtha and then crystallized out. The swearing process consists in heating the crude wax to such a temperature that the softer portions are melted and flow away with the oil. In the process patented by N. M. Henderson (Nos. 1291 of 1887 and 11,799 of 1891), a chamber, 52 ft. by 13 ft. by 10 ft. high, heated by steam-pipes, and provided with large doors and ventilators for cooling, is fitted with a number of superimposed trays, 21 ft. by 6 ft. by 6 in. deep. These rest on transverse heating pipes, and each tray has a diaphragm of wire gauze. The bottom is ventilated by short pipes fitted with swivel nozzles, worked on a vertical shaft. The diaphragms are covered with ½ in. of water, and the crude paraffin is melted and pumped through charging-pipes on to its surface. When the paraffin has solidified, the water is drawn off, leaving the cake resting on the gauze. Doors and ventilators are then closed, and the chamber is heated, whereupon the liquefied impurities are drained off until the outflowing paraffin sets on a thermometer bulb at 130° F. The remainder is melted and decolorized by agititation with finely powdered charcoal. The charcoal is mainly separated by subsidence, and the paraffin drawn off into filters, whence, from the suspended charcoal, it runs into moulds, and is thus formed into cakes of suitable size for packing. The lubricating oils are refined by the use of sulphuric acid and alkali, substantially in the same manner as the burning oils.

The following table shows the average yield, in 1895, of the various commercial products from crude shale-oil at two of the principal Scottish refineries. The percentages are, however, often varied to suit market requirements:—

From the ammoniacal liquor the ammonia is driven off by the application of heat in stills, the evolved vapour being conducted into "cracker-boxes" which are now usually of circular form, from 5 to 8 in. in diameter, and 6 to 12 in. in depth. In these boxes the ammonia is brought into contact with sulphuric acid of about 50° Tw., and is thus converted into sulphate. Wilson's form of cracker-box, which is now generally in use, is provided with an arrangement for the automatic discharge on to a drying table of the sulphate of ammonia as it is deposited in the well of the box, and the process is worked continuously. For the heating of the ammoniacal liquor the ordinary horizontal boiler-stills formerly used have been superseded by "column" stills, in which the liquor is exposed over a large area, as it passes from top to bottom of the still, to the action of a current of steam.

*PARAFFIN,* in chemistry, the generic name given to the hydrocarbons of the general formula C_{n}H_{2n+2}. Many of these hydrocarbons exist as naturally occurring products, the lower (gaseous) members of the series being met with as exhalations from decaying organic matter, or issuing from fissures in the earth; and the higher members of the series occur in petroleum (chiefly American) and ozokerite. They may be synthesized by reducing the alkyl halides (preferably the iodides) with nascent hydrogen, using either sodium amalgam, zinc and hydrochloric acid, concentrated hydroiodic acid (Berthelot, *Jour. prak. Chem.* 1868, 104, p. 103), aluminium amalgam (H. Wislicenus, *ibid.*, 1896 (2), 54) or the zinc-copper couple (J. H. Gladstone and A. Tribe, *Ber.*, 1873, 6, p. 202 seq.) as reducing agents.

They may also be derived from alkyl halides by heating to 120-140° with aluminium chloride in the proportion of three molecules of alkyl halide to one molecule of aluminium chloride (B. Köhlein, *Ber.*, 1885, 16, p. 506); by heating with zinc and water to 150-160° (E. Franklin-James, *Ann.*, 1849, 71, p. 203; 1850, 74, p. 41). R_{2}Cl+2HCl→2H_{2}R+2Cl, by reduction of water, Zn_{2}F_{2}+2H_{2}O→2F+2Zn(OH)_{2}, by conversion into zinc alkyls, which are then decomposed by water, Zn_{2}I_{2}+2H_{2}O→2H_{2}+2Zn(OH), by conversion into the Grignard reagent with metallic magnesium and decomposition of this either by water, dilute acids or preferably ammonium chloride (J. Houben, *Ber.*, 1905, 38, p. 3019). R_{2}Mg+H_{2}O→H_{2}+Mg(OH), by the action of potassium hydride (H. Meissner, *Comptes rendus*, 1902, 134, p. 389); and by the action
of sodium, in absolute ether solution (A. Wurtz, Ann. chim. phys., 1855 (3), 44, p. 275), 2RI+2Na = R-R+2NaI. They may also be obtained by the reduction of the higher fatty acids with hydrosulphuric acid (F. Krafft, Ber., 1882, 15, pp. 1687, 1711), C,H,0, + 6H = C,H,0, + 3H, by the conversion of ketones into ketonic chlorides by the action of phosphorus pentachloride, these then being reduced by hydrosulphuric acid,

\[
\]

by the reduction of unstaturated hydrocarbons with hydrogen in the presence of a "contact" substance, such, as example, as reduced nickel or cobalt (P. Sabatier and J. B. Senderens, Ann. chim. phys., 1905 [8], 4, pp. 319, 433): by the elimination of carbon dioxide from the fatty acids on heating their salts with soda or baryta, CH,CO,Na + NaOH = CH,COONa + CO, by heating their barium salts with sodium methylate in situ (L. Mai, Ber., 1889, 22, p. 2133); by the elimination of the fatty acids (Kolbe, Ann., 1849, 69, p. 257), 2C,H,0, + C,H, + 2C,O + H,O; and by the action of the zinc alkyls on the ketonic chlorides, (C,H,CO, + Zn(C,H,)=C,H,=ZnCl,).

The lowest members of the series are gases at ordinary temperature; those of carbon content C, to C, are colourless liquids, and the higher members from C, onwards are crystalline solids. The highest members only volatilize without decomposition when distilled under diminished pressure. They are not soluble in water, although the lower and middle members of the series are readily soluble in alcohol and ether. The solubility, however, decreases with increase of molecular weight, so that the highest members of the series are almost insoluble in these solvents. The specific gravity increases with the molecular weight but always remains below that of water. The paraffins are characterized by their great inertness towards most chemical reagents. Fuming sulphuric acid converts the middle and higher members of the series into sulphonic acids and dissolves the lower members (Dr. J. W. Frankland, Journ. Chem. Soc., 1838, 20, p. 664). Dilute nitric acid, when heated with the paraffins in a tube, converts them into secondary and tertiary nitro-compounds (M. Konowalow, Ber., 1859; 28, p. 1852), while long boiling with strong nitric acid or nitro-sulphuric acid converts the middle and higher members of the series partly into primary mono- and di-nitro compounds and partly oxidizes them to carboxylic, oxalic and succinic acids (Worstall, ibid., 20, p. 202; 21, p. 211). Fuming nitric acid only reacts slowly with the normal paraffins at ordinary temperature, but with those containing a tertiary carbon atom the reaction

is very energetic, oxidation products (fatty acids and dibasic acids) and a small quantity of poly nitro compounds are obtained (W. Markownikow, Centralbl., 1889, i, p. 845; Ber., 1899, 32, p. 1095). Chloro compounds with the paraffins, readily substituting hydrogen. Isomeric hydrocarbons in this series first appear with butane, the number increasing rapidly as the complexity of the molecule increases. For a means of determining the number of isomers see E. Cayley, Ber., 1875, 8, p. 1956; F. Herrmann, Ber., 1898, 31, p. 91.

For Methane see MARSH Ethane, C,H, occurs in crude petroleum. It may be prepared by the general methods given above; by heating mercury ethyl with concentrated sulphuric acid (C. Schollem, Ann., 1864, 132, p. 234); or by heating acetic anhydride with Barium and mercury (C. Kellner, 1864, 135, p. 703). (CH,CO)O + BaO = CH, + Ba(C,H,CO) + CO. It is a colourless gas which can be liquefied at -20° C. by a pressure of 46 atmospheres. By slow combustion it yields first water and acetaldehyde, which then oxidizes to oxides of carbon and water (W. A. Bone; see FLAME), whilst in oxygenated air at 400° it gives ethyl alcohol, together with acetaldehyde and traces of formaldehyde (Bone, Proc. Chem. Soc., 1904, 29, p. 127).

Dimyryl (hexacontane), C,H, is prepared by fusing myricyl iodide with sodium (H. Helis and U. Ber., 1889, 22, p. 502). It is only very slightly soluble in alcohol and ether.

PARAGUAY, a term for which there is a model of excellence or pattern of perfection, hence some person or thing which has no equal. The word was adopted from the O. Fr. paragone, Mod. paragon, Ital. paragone and Span. paragones. The Spaniards has usually been taken as the source, and the word explained as from the prepositional phrase para con, in comparison with. But the word first appears in Italian, meaning a "touchstone." The Italian word may be connected with the Gr. παραγωγή, to sharpen by the use of a whetstone (ἀκροφύτης). The term has been used in several technical applications, e.g. in printing, of a large style of type between "great primer" and "double pica," now usually called "two-line long primer."" A diamond weighing more than 100 carats; and formerly of a fabric used for hangings in the 17th and 18th centuries.

The river Paraguay, running from north to south, divides the republic into two sections, the eastern section, or Paraguay Oriental, being the most important. The
western section forms part of the great plain called the Gran Chaco (see Argentina), and is to a large extent unexplored. Paraguayan proper, or the country between the Paraguay and the Paraná, is traversed from north to south by the intervening belt of highlands, which are known as the Cordillera Argentina, Cordillera Urubamba, &c., but partake rather of the character of plains, owing to the continued inundation and outwork of the great interior plateau of Brazil. The elevation nowhere much exceeds 2200 ft. On the western side these highlands terminate with a more or less sharply defined edge, the country sloping gradually up to their bases in gentle undulations with open, ill-defined valleys; on the eastern side they send out broad spurs enclosing deep-cut valleys, and the whole country retains more of an upland character. The tributaries that flow westward to the Paraguay are consequently to some extent navigable, while those that run eastward to the Paraná are interrupted by rapids and falls, often of a formidable description. The Pilcomayo, the largest western tributary of the Paraguay, and an important frontier river, is only navigable in its upper and lower reaches. From the Asunción plateau southwards, near the confluence of the Paraguay and Paraná, there is a vast stretch of marshy country, draining partly into the Ypoa lagoon, and smaller tracts of the same character are found in other parts of the lowlands, especially in the valley of the Paraguay. Many parts of the country sloping to the Paraná are nearly covered with dense forest, and have been left in possession of the sparsely scattered native tribes. But the country sloping to the Paraguay, and comprising the greater part of the settled districts, is, in keeping with its proximity to the Atlantic, with that of Argentina, grassy and open, though the hills are usually covered with grass, and clumps of trees are frequent in the lowlands. Except in the marshy regions and along the rivers, the soil is dry, porous and sandy.

Geology.—Little is known of the geology of Paraguay. A large part of the area is covered by Quaternary deposits, which completely conceal the solid foundation on which they rest. The hills and plateaus appear to be composed chiefly of the same sandstone series which in the Brazilian province of Rio Grande do Sul contains seams of coal, with plant remains similar to those of the Karharbâriâ series of India (Permian or Upper Carboniferous). It is probable, also, that the Palaeozoic rocks of Mattos Grosso extend into the northern part of the country.

Minerals.—The mineral resources of Paraguay have been concealed by the Jesuits may have had no existence; and though iron was worked by F. S. Lopez at Ibarry (70 m. south-east of Asunción), and native copper, oxide of manganese, marbles, line and salt have been found, the real wealth of the country consists rather in the variety and extent of its vegetable products.

Climate and Fauna.—The year in Paraguay is divided into two seasons—summer, lasting from October to March, and winter, from April to September. December, January and February are generally the hottest months, and May, June, July and August the coldest. The mean temperature for the year seems to be about 75° or 76°; for summer, 81°; for winter, 71°. The annual rainfall is about 45 in., fairly well distributed throughout the year, though it has a tendency to occur in August, September, November and October. The prevailing winds blow from the north or south. The south wind is dry, cool and invigorating, and banishes mosquitoes for a time; the north wind is hot, moist and relaxing. Violent winds and thunderstorms are common.

The fauna of Paraguay proper is practically the same as that of Brazil. Caymans, water-hogs (capinches), several kinds of deer (Cerus paludosus the largest), oones, opossums, armadillos, vampires, the American otirth, the ibis, the jabiru, ibises, peacocks, the palma- medes cornuta, parrots and parakeets, are among the more notable forms. Insect life is peculiarly abundant; the red stump-like ant-hills are a feature in every landscape, and bees used to be kept in all the mission villages.

Population.—The great majority of the inhabitants are of Indian (Guaraní) descent, with very slight traces of foreign blood. Civilization has not made much progress, and the habits of the people are more primitive than those in the more advanced neighbouring republics. As a general rule the Paraguayans are indolent, especially the men. Climatic conditions obviate the necessity of any superfluity of clothing. A cotton chemise, and a white manifold wrapped in Moorish fashion over head and body, constitute the dress of the women; a cotton shirt and trousers that of the men. Boots and shoes are worn only by the upper classes. Gout and leprosy are the only endemic diseases, but the great proportion of the population suffer from diarrhoea and dyspepsia. The common language of the country is Guaraní, although in a few districts Tupi is spoken. The country people as a rule understand a little Spanish, if living near any trading centre. "New Australia" is a pastoral and agricultural settlement, originally founded in 1893 by immigrants from Australia as an experiment in communism. The colony failed at first, and was reconstituted in 1894. The settlers numbered 161 in 1908. Immigration is on a small scale (1024 in 1908), but tends to increase; it is encouraged by the government, which seeks to divert to Paraguay some portion of the Italian labour immigrant into Brazil and Argentina. In 1908 the total foreign population numbered about 18,000, half of whom were natives of Argentina. The principal towns are Asunción, the capital (pop. 1905, 60,259), Villa Rica (25,000), Concepción (15,000) and Villa del Pilar (10,000); these are described in separate articles. Encarnación on the Paraná has a large transit trade.

Government.—The constitution of the republic was voted by a constituent assembly on the 25th of November 1870. Legislative power is vested in a Congress consisting of a Senate and a Chamber of Deputies, elected by universal manhood suffrage in the proportion of one senator for every 12,000 inhabitants and one deputy for every 6000. Every member of Congress receives a salary of about £200. The head of the executive is the president, chosen by an electoral college for four years, and only re-eligible after eight consecutive years. He is aided by a cabinet of five ministers for transport and revenue. Should he be impeached or die during his term, or otherwise become unable to fulfil his duties, the president is succeeded by the vice-president (similarly elected), who is ex officio chairman of the Senate. The highest judicial authority is the Supreme Court, which is empowered to decide upon the constitutional validity of acts passed by Congress; its three members are appointed for four years by Congress, subject to the approval of the president. There are five courts of appeal, and inferior tribunals in all the large towns. The civil and criminal codes at Argentina have been adopted, almost without change. For purposes of local administration the republic is divided into 23 counties (partidos), which are subdivided into communes.

Religion and Instruction.—Roman Catholicism is the established religion, but the constitution guarantees full liberty to all other creeds. Asunción, the only bishopric in the state, is in the archbishopric of Buenos Aires. Education is backward and was long neglected. By law it is free and compulsory, but in some districts the attendance of many children is impossible. In 1907 there were 551 primary schools with 41,000 pupils.

Finance.—In 1898 the standing army, including cavalry, infantry and artillery, numbered about 1195 men; and there were five government steamers used for transport and revenue purposes.

Provision. The financial situation of Paraguay has been a source of anxiety for many years. In 1885, after interest had been unpaid for 11 years on bonds amounting to £1,505,400, an agreement was made for the issue of new scrip to the value of 890,000 in quittance of principal and interest; the public lands were again being ceded to the bondholders as compensation. In 1895 an arrangement was made for a reduction of the rate of interest, for the funding of the arrears, and for the creation of a sinking fund. The latter scheme proved successful, and the public lands were again exchanged for the bonds. On the 31st of December 1898 the total indebtedness of the country was £831,850. Besides the London debt, there are many other claims on Paraguay, including (1908) about £1,950,000 due to Brazil, about £2,500,000 due to Argentina, and an annual debt of £90,000 of the guarantor debt due to the Paraguay Central railway. The total indebtedness of the country is £7,950,000. The revenue derived mainly from import duties, and the most important branches of expenditure are the salaries of public officials, the army, public instruction and debt. The estimated revenue and expenditure for the three years 1906–1908 are shown in the following table:—
Revenue

The budget for 1906 remained in force in 1907 and 1908.

Industry.—The principal industries are the cultivation and preparation of yerba maté (Paraguayan tea), cattle-farming, fruit-growing, tobacco-planting and timber-cutting. Yerba maté, classified as *Ilex paraguariensis*, is a shrub. The leaves are stripped, washed, rolled, roasted and then inclosed in sacks and sent chiefly to Argentina. Paraguayan tea is used in place of the ordinary tea or coffee in many parts of South America. Medical experts state that the beverage infused from the leaves has a stimulating effect and is used to treat various ailments. The quantity exported from Paraguay in 1908 was 413,333 tons. The majority of the yerbales (tea plantations) were formerly the property of the government, but have been acquired by private enterprise. An import duty about yerba maté is the small expense necessary for its production, and the cheap rate, notwithstanding the high tariff on its importation, at which it can be placed on the Argentine market as compared with ordinary tea or Brazilian coffee.

The cattle industry comes next in importance. The number of animals was 5,859,000 in 1906, which decreased to 5,802,000 in 1908; an increase of about 45% since the census of 1899. The animals are small, but Durham and Hereford bulls have been introduced from Argentina to improve the breed. The increase in the herds has been steady. The owners of plantations in Paraguay and Uruguay try to work the farming on Paraguay for the preparation of rasajo (jerked beef) and the manufacture of extract of meat. Both grasses and climate are advantageous on a farming and pastoral code.

Oranges are exported to Buenos Aires, Rosario and Montevideo, and are largely used for fattening hogs. The orange groves are often uncultivated, but yield abundantly; 10,796,000 dozens of oranges were exported in 1908. Some plantations are also sown with sugar-cane, cotton, coffee and ramie are cultivated. Tobacco, although of inferior quality, is grown to a considerable extent; the quantity exported rose from about 35 tons in 1900 to 1304 in 1908. The staple diet of the Paraguayans is still, as when the Spaniards first came, maize and mandioca (the chief ingredient in the excellent chimba or Paraguayan bread), varied, it may be, by the seeds of the *Victoria regia* of the lakes. The incised leaves of the plant are an excellent food, and the fresh or dried blossoms are the great feature of several of the lakes and rivers.

The forests abound in such timber as quebracho, cedar, curupay, lapacho and urunday. Some of these, such as the lapacho and quebracho, are of rare excellence in durability, as is shown by the wooden staves of pasture and of Germany. The staple diet of the Paraguayans is still, as when the Spaniards first came, maize and mandioca (the chief ingredient in the excellent chimba or Paraguayan bread), varied, it may be, by the seeds of the *Victoria regia* of the lakes. The incised leaves of the plant are an excellent food, and the fresh or dried blossoms are the great feature of several of the lakes and rivers.

The incised leaves of the plant are an excellent food, and the fresh or dried blossoms are the great feature of several of the lakes and rivers.

Commerce.—The commercial situation of Paraguay has improved in consequence of the investment of foreign capital in industrial enterprises. The rise in the terms of the raw materials and in the prices of the staple exports has been accompanied with a corresponding rise in the prices of the manufactured goods. The exports of Paraguay, the most important of which are tobacco, cotton goods, manufactured goods, wines, rice, flour, lumber and office supplies, have increased steadily.

Communications.—Numerous ocean-going liners, most of which fly the Brazilian or the Argentine flag, ply on the Paraguay and the Paraná, smaller vessels ascend the tributary streams, which are watered by the fumadas and by the works on the Paraná. The communication of the republic is the Paraguay-Central which was opened in 1906 between Buenos Aires and Asunción. The railway from the port of Pirapar (154 m.) The completion of the line to Encarnación was then undertaken (1906-1911), a train-ferry across the Paraná affording connexion with Posadas. These extensions, and the prolongation of the line into Argentina to the north, carried out mainly at the cost of the Argentine government, which acquired a controlling interest in the Paraguay Central. They were intended to shorten the journey between Buenos Aires and Asunción from 5 days to 3 hours. There are some fairly good wagon roads, and the government appropriates annually a considerable sum for their extension.

Post and Telegraph.—Paraguay entered the Universal Postal Union in 1884. Telegraph lines connect Asunción with other towns, and two cables put the republic in communication with the rest of the world by way of Corrientes and Posadas.

Money and Credits.—The banks open for business in 1904 were the National Bank, the Torrecilla Bank, the Bank of Los Ríos & Co., and the Agricultural Bank: the latter had a capital of £207,900, advanced by the government, and lends money to the agricultural and industrial classes. The Paraguayan Bank, with capital of £500,000, was opened in 1905, and a state bank (Banco de la República) was not established until the middle of 1906 when a capital of £1,253,439 was opened on the 30th of June 1906. The Conversion Office, which is authorized to sell or lend gold, receives a fixed revenue of £30,000 from certain import and export duties; it was reorganized by a law of May 1898, which increased the advances of the credit department of the government. The gold and silver coinage of Paraguay were legally standardized as identical with those of Argentina (5 gold dollars or pesos = £1); but paper money is about the only circulating medium, and gold commands a premium (1600% in December) over the value of the paper or currency dollar is about 48. 8d. For purposes of conversion the gold dollar has been taken at £1 throughout this article, and the currency dollar at 50 = £1.

Height and Measures.—The metric system is officially adopted, but the weights in common use are the tonela (2025 lb), the quintal (101.4 lb), the arroba (25.35 lb), the libra (1.04 lb) and the onza (0.016 lb). The unit for liquid measure is the cuarta (15.64 gallons); the unit for dry measure is the fanega (1 bushel). The land measures are the legua (2-689 m.), the zinca (69 sq. yds.), and the legua cuadrada (12 sq. m.).

History.—In 1527 Sebastian Cabot reached Paraguay and built a fort called Santo Espirito. Asuncion was founded on the 15th of August 1535 by Juan de Ayolas, and his successor, Martinez de Irala, determined to make it the capital of the Spanish possessions east of the Andes. From this centre Spanish adventurers pushed east to La Guayra, beyond the Paraná, and west into the Gran Chaco; and before long vast numbers of the less warlike natives were reduced to serfdom. The name Paraguay was applied not only to the country between the Paraguay and the Paraná, but to the whole Spanish territory, which now comprises parts of Brazil, Uruguay and the Argentine provinces of Buenos Aires, Entre Rios, Corrientes, Misiones, and part of Santa Fé. It was not till 1620 that Paraguay proper and Rio de la Plata or Buenos Aires were separated as distinct governments, and they were both dependent on the vice-royalty of Peru, till 1776, when Buenos Aires was erected into a vice-royalty, and Paraguay placed under its jurisdiction. The first Christian missions in Paraguay were established by the Franciscans—Armenta, Lebron, Solano (who was afterwards canonized as the “Apostle of Paraguay”) and Bolanos—between 1542 and 1560; but neither they nor the first Jesuit missionaries, Salonio, Field and Ortega, were allowed to make their enterprise permanent success. This fell to the lot of the second band of Jesuits, Cataldo, Mazeta and Lorenzana, who began work in 1605. Though they succeeded in establishing a kind of “imperium in imperio,” and were allowed to drill the natives to the use of arms, the Jesuits never controlled the government of Paraguay; indeed they had nearly as often to defend themselves from the hostility of the governor and bishop at Asuncion as from the invasions of the Paulistas or Portuguese settlers of São Paulo. It was only by the powerful assistance of Zabala, governor of Buenos Aires, that the anti-Jesuit and quasi-national party which had been formed under Antequera was crushed in 1735. In 1765, however, Ferdinand VI, eager to take advantage of the Portuguese, in exchange for the fortified village of Colonia del Sacramento (Uruguay), both the district of La Guayra and a territory of some 20,000 sq. m. east of the Uruguay. The Jesuits resisted the transference, and it was only after several engagements that they were defeated by the combined forces of Spain and Portugal. The treaty was revoked by Spain in 1761, but the missions never recovered their prosperity, and the Jesuits were finally expelled in 1769. In 1811 Paraguay declared itself independent of Spain; but 1814 was a despotism in the hands of Dr J. G. R. Francia (q.v.). On Francia’s death, in 1840, the chief power passed to his nephew, Carlos Antonio Lopez (q.v.), who in 1862 succeeded by his son Francisco Solano Lopez. In 1864 a dispute arose between the younger Lopez and the Brazilian government, and Lopez marched an army through Argentine territory to invade southern Brazil.
This act induced the governments of Brazil, Brazil and Argentina to combine for the purpose of supressing Lopez. The invasion (March, 1870) by a small army of about 3,700 men, involving an enormous sacrifice of life and treasure lasting for five years, only coming to a close when the Paraguayan forces were totally defeated and Lopez was killed at the battle of Aquidaban on the 1st of March 1870. During this warfare every male Paraguayan capable of bearing arms was forced to fight, whole regiments being formed of boys of from 12 to 15 years of age. Even women were used as beasts of burden to carry ammunition and stores, and when no longer capable of work were left to die by the roadside or murdered to avoid any ill consequences occurring from their capture. When the war broke out the population of Paraguay was 1,337,430; when hostilities ceased it consisted of 28,736 men, 106,243 women above 15 years of age, and 85,079 children. During the retreat of the Paraguayans the dictator ordered every town and village passed through to be razed to the ground, and every living animal for which no use could be found to be slaughtered. When the end came the country and people were in a state of absolute prostration.

Upon the death of Lopez the government was administered by a triumvirate consisting of Cirió Rivarola, Carlos Loizaga, and José Diaz de Bedoza, until, in November 1879, the present constitution was formulated. The policy of Brazil was for a time directed towards the annexation of Paraguay; the debt due to Brazil on account of the war was assessed at £40,000,000, a sum which Paraguay could never hope to pay; and it was not until 1876 that the Brazilian army of occupation was wholly withdrawn. But the rivalry between Brazil and Argentina, and the necessity of maintaining the balance of power among the South American republics, enabled Paraguay to remain independent. No violent constitutional change took place after 1870, though there have been spasmodic outbreaks of revolution, as in 1881, in 1894, in 1898, in December 1904—when a somewhat serious civil war was ended by the peace of Pilocayo—in July 1908 and in September 1909. None of these disturbances deeply or permanently affected the welfare of the republic, nor were all of them accompanied by bloodshed. Under the presidency of J. B. Egusquiza (1894-1898) the boundary dispute with Argentina, which had been the cause of long-lasting war, was finally settled, owing to the success of the revolution, which forced the president to resign. The main interest of recent Paraguan history is economic, rather than political. In that history the gradual development of commerce, the financial reforms in 1893, and the extension of the Paraguay Central railway after 1906, were events of far greater importance than any political movement which took place between 1870 and 1910.

PARAHYBA (PARAHYBA or PARAHYBA DO NORTE), a state of north-eastern Brazil, bounded N. by Rio Grande do Norte, E. by the Atlantic, S. by Pernambuco, and W. by Ceará. Pop. (1890), 457,422; (1900), 490,784. Area, 28,854 sq. m. It consists of a narrow coastal zone, 30 to 40 m. wide, along the seaboard, behind which the country rises sharply to a highland region forming part of the great central plateau of Brazil. The long, dry season (April to October), together with occasional devastating droughts (secas) lasting two or more years, prevents the development of forests and damages the agricultural and pastoral industries of the state. There is only one river of importance, the Parahyba do Norte, which crosses the southern part of the state from west to east with a course of about 240 m. The state is poorly watered and covered with a scanty vegetation suitable for pasturage only. Stock-raising is favoured by the existence of a bromeliacious plant, called mecumira, which is sufficiently juicy to satisfy the thirst of the animals. On the low lands and along some of the river valleys agriculture is the chief occupation of the people; cotton and sugar are largely produced and some tobacco is grown. The exports include hides, skins, cotton, sugar and tobacco. Rubber of the Ceará type is also found and forms an item among the smaller exports.

The eastern extremity of the state is served by a railway, originally called the Conde d’Eu railway but now forming part of the Great Western of Brazil system, which runs westward from the northward from Independencia (72 m.), where it connects with the extension towards the north of the Nova Cruz line, and a branch runs southward to Pilar, 15 m. from its junction and 46 m. from Parahyba. Another small branch runs westward from the station of Mulungu to Alagóa Grande (14 m.). The capital is Parahyba (g.t.), and other important towns, with the populations (in 1890) of their municipalities, which include large rural districts and sometimes several other towns, are: Arcia (26,500); Bananeiras (20,058); Campina Grande (21,475); Guarabira (26,053); Manangaupe (20,754); Pilar (10,133, town); Pombal (12,804); and Souza (11,135).

Parahyba formed part of the original grant, known as the capitanía of Itamaracá, from the Portuguese crown to Pero Lopes de Souza. It was not settled until 1584, when a fort was erected near the present port of Cabedello under the name of São Filipe.

PARAHYBA (PARAHYBA DO NORTE), a city and port of Brazil, capital of Parahyba state, on the right bank of the Parahyba do Norte River, 11 m. above its mouth and 65 m. N. of Recife. Pop. (1891), 18,658, including Cabedello; (1908, estimate), 20,000. Parahyba is the starting-point of the Conde d’Eu railway, now a part of the Great Western of Brazil system, which includes a main line to Independencia, where it connects with the Natal & Nova Cruz line of Rio Grande do Norte, and a branch to Cabedello. The entrance to the Parahyba do Norte River being obstructed by a stone reef and sand bars, only vessels drawing less than 14 ft. can effect an entrance. The “Varadouro,” as the lower part of the city is called, is built on the margin of the river and is devoted principally to commerce. Behind this is a low hill on whose northern slope and broad summit the upper city is built, and a tramway line runs to the suburb of Trincheira. There are some good public buildings, including the parish church (matriz) of N.S. das Neves, the old Franciscan convent and church, the government palace, and the treasury. There are a normal school, a lyceum, a national gymnasium, and a school for marine apprentices.

Parahyba was founded in 1835. It was called Frederikstadt by the Dutch, who occupied the Franciscan convent, as a government place, and Cippé, in honour of the king of Spain when the Dutch were expelled. Its original name was resumed on the separation (1904) of Portugal and her colonies from Spanish rule.

PARAHYBA DO SUL, a river of Brazil, having its source on the campos of Bocaina, on the northern slope of the Serra do Mar in the western part of the state of São Paulo, and flowing at first south-westerly and then after a horse-shoe curve in the vicinity of Jacarehy in a general E.N.E. direction to the Atlantic in lat. 21° 38’ S. Its upper course for a distance of 80 m., or to the confluence of the Parahyba, is known as the Parahytinga. The navigable channel from São Fidelis to the
PARALDEHYDE—PARALLAX

Atlantic is 54 m. long, and the total length of the river, including the Parábyngna, is 540 m. Its source is about 490 ft. above sea-level. The Parábyngna passes through a fertile, long-settled country, and a part of which was for many years the principal coffee-producing region of Brazil. Its lower course passes through the rich alluvial sugar-producing district of Campos. Among the towns on the Parábyngna are Campos, São Fidelis, Parábyngna do Sul, Juiz de Fora, Barra do Pirahy (railway junction), Rezende, Queuiz and Lorena.

PARALDEHYDE, in medicine, a clear colourless liquid (for the chemistry see ALDEHYDES), soluble in 1 in 10 of water and freely in alcohol. Paraldehyde is a powerful hypnotic, giving a refreshing quiet sleep which is not followed by unpleasant after effects. As it does not depress the heart when used in medicinal doses, it may be given to patients suffering from cardiac disease. It is much used to produce sleep in the insane. As it is largely excreted by the lungs it may be found useful in bronchial asthma. When taken continuously the drug soon loses its power as a hypnotic. Its unpleasant taste usually prevents the formation of a paraldehyde habit, but it occasionally occurs with symptoms resembling delirium tremens. When taken in an overdose paraldehyde kills by producing respiratory failure.

PARALLAX (Gr. παράλλαξις; alternately, in astronomy, the apparent change in the direction of a heavenly body when viewed from two different points. Geocentric parallax is the angle between the direction of the body as seen from the surface of the earth and the direction in which it appears from the centre of the earth. Annual parallax is the angle between the direction in which a star appears from the earth and the direction in which it appears from the centre of the sun. For stellar parallaxes see STAR; the solar parallax is discussed below.

Solar Parallax.—The problem of the distance of the sun has always been regarded as the fundamental one of celestial measurement. The difficulties in the way of solving it are very great, and up to the present time the best authorities are not agreed as to the result, the effect of half a century of research having been merely to reduce the uncertainty within continually narrower limits. The mutations of opinion on the subject during the last fifty years have been remarkable. Up to about the middle of the 19th century it was supposed that transits of Venus across the disk of the sun afforded the most trustworthy method of making the determination in question; and when Encke in 1824 published his classic discussion of the transits of 1761 and 1769, it was supposed that we must wait until the transits of 1874 and 1882 had been observed and discussed before any further light would be thrown on the subject. The parallax 8-5776° found by Encke was therefore accepted without question, and was employed in the Nautical Almanac from 1834 to 1886. Doubt was first thrown on the accuracy of this number by an announcement from Hansen in 1862 that the observed parallactic inequality of the moon was irreconcilable with the accepted value of the solar parallax, and indicated the much larger value 8-97°. This result was soon apparently confirmed by several other researches founded both on theory and observation. Did the evidence appear to fit the value 8-95° used in the Nautical Almanac from 1870 to 1881. The most remarkable feature of the discussion since 1862 is that the successive examinations of the subject have led to a continually diminishing value, so that at the present time it seems possible that the actual parallax of the sun is almost as near to the old value of Encke as to that which first replaced it. The value of 8-848°, determined by S. Newcomb, was used from 1882 to 1900; and since then the value 8-86° has been employed, having been adopted at a Paris conference in 1896.

Five fundamentally different methods of determining the distance of the sun have been worked out and applied. They are as follows:—

I. That of direct measurement.—From the measures of the parallax of either Venus or Mars the parallax of the sun can be immediately derived, because the ratios of distances in the solar system are known with the last degree of precision. Transits of Venus and observations of various kinds on Mars are all to be included in this class.

II. The second method is in principle extremely simple, consisting merely in multiplying the observed velocity of light by the time which it takes light to travel from the sun to the earth. The velocity is now well determined; the difficulty is to determine the time of passage.

III. The third method is through the determination of the mass of the earth relative to that of the sun. In astronomical practice the masses of the planets are commonly expressed as fractions of the mass of the sun, the latter being taken as unity. When we know the mass of the earth in gravitational measure, its product by the denominator of the fraction just mentioned gives the mass of the sun in gravitational measure. From this the distance of the sun can be at once determined by a fundamental equation of planetary motion.

IV. The fourth method is through the parallactic inequality in the moon's motion. For the relation of this inequality to the solar parallax see MOON.

V. The fifth method consists in observing the displacement in the direction of the sun, or of one of the nearer planets, due to the motion of the earth round the common centre of gravity of the earth and moon. It requires a precise knowledge of the moon's mass. The uncertainty of this mass impairs the accuracy of the method.

I. To begin with the results of the first method. The transits of Venus observed in 1874 and 1882 might be expected to hold a leading place in the discussion. No purely astronomical enterprise was ever carried out on so large a scale or at so great an expenditure of money and labour as was devoted to the observations of these transits, and for several years before their occurrence the astronomers of every leading nation were busy in discussing methods of observation and working out the multifarious details necessary to their successful application. In the preceding century reliance was placed entirely on the observed moments at which Venus entered upon or left the limb of the sun, but in 1874 it was possible to determine the relative positions of Venus and the sun during the whole course of the transit. Two methods were devised. One was to use a heliometer to measure the distance between the limbs of Venus and the sun during the whole time that the planet was seen projected on the solar disk, and the other was to take photographs of the sun during the period of the transit and subsequently measure the negatives. The Germans laid the greatest stress on measures with the heliometer; the Americans, English, and French on the photographic method. These four nations sent out well-equipped expeditions to various quarters of the globe, both in 1874 and 1882, to make the required observations; but when the results were discussed they were found to be extremely unsatisfactory. It had been supposed that, with the greatly improved telescopes of modern times, contact observations could be made with much greater precision than in 1761 and 1769, yet, for some reason which it is not easy to explain, the modern observations were but little better than the older ones. Discrepancies difficult to account for were found among the estimates of even the best observers. The photographs led to no more definite result than the observations of contacts, except perhaps those taken by the Americans, who had adopted a more complete system than the Europeans; but even these were by no means satisfactory. Nor did the measures made by the Germans with heliometers come out any better. By the American photographs the distances between the centres of Venus and the sun, and the angles between the line adjoining the centres and the meridian, could be separately measured and a separate result for the parallax derived from each. The results were:

<table>

PARALLAX

761

The German measures with the heliometer gave apparently concordant results, as follows:—

Transit of 1874: par. = 8.876°.
Transit of 1882: " = 8.879°.

The combined result from both these methods is 8.875°, while the combination of all the contact observations made by all the parties gave the much smaller result, 8.794°. Had the internal contacts alone been used, which many astronomers would have considered the proper course, the result would have been 8.776°.

In 1877 Sir David Gill organized an expedition to the island of Ascension to observe the parallax of Mars with the heliometer. By measurements giving the position of Mars among the neighboring stars in the morning and evening, the effect of parallax could be obtained as well as by observing from two different stations; in fact the rotation of the earth carried the observer himself round a parallel of latitude, so that the comparison of his own morning and evening observations could be used as if they had been made at different stations. The result was 8.78°. The failure of the method based on transits of Venus led to an international effort carried out on the initiative of Sir David Gill to measure the parallax by observations on those minor planets which approach nearest the earth. The scheme of observations was organized on an extended scale. The three bodies chosen for observation were: Victoria (June 10 to Aug. 26, 1888); Iris (Oct. 12 to Dec. 10, 1888); and Sappho (Sept. 18 to Oct. 25, 1888). The distances of these bodies at the times of observation were somewhat less than unity, though more than twice as great as that of Mars in 1877. The drawback of greater distance was, however, in Gill's opinion, more than compensated by the accuracy with which the observations could be made. The instruments used were heliometers, the construction and use of which had been greatly improved, largely through the efforts of Gill himself. The planets in question appeared in the telescope as star-like objects which could be compared with the stars with much greater accuracy than a planetary disk like that of Mars, the apparent form of which was changed by its varying phase, due to the different directions of the sun's illumination. These observations were worked up and discussed by Gill with great elaboration in the *Annals of the Cape Observatory,* vols. vi. and vii. The results were for the solar parallax \( \pi = \) :

From Victoria, \( \pi = 8.801° = \pm 0.006°. \)
Sappho, \( \pi = 8.798° = \pm 0.011°. \)
Iris, \( \pi = 8.812° = \pm 0.009°. \)

The general mean result was 8.802°. From the meridian observations of the same planets made for the purpose of controlling the elements of motion of the planets Auwers found \( \pi = 8.806°. \)

In 1898 the remarkable minor planet Eros was discovered, which, on those rare occasions when in opposition near perihelion, would approach the earth to a distance of 0.16. On these occasions the actual parallax would be six times greater than that of the sun, and could therefore be measured with much greater precision than in the case of any other planet. Such an approach had occurred in 1892, but the planet was not then discovered. At the opposition of 1900–1901 the minimum distance was 0.32, much less than that of any other planet. Advantage was taken of the occasion to make photographic measures for parallax at various points of the earth on a very large scale. Owing to the difficulties inherent in determining the position of so faint an object among a great number of stars, the results have taken about ten years to work out. The photographic right ascensions gave the values 8.86° + 0.007° ± 0.0027° (Hinks) and 8.86° + 0.0067° ± 0.0025° (Perrine); the micrometric observations gave the value 8.86° ± 0.004° (Hinks).1

II. The velocity of light (c) has been measured with all the precision necessary for the purpose. The latest result is 299,860 kilometres per second, with a probable error of perhaps 30 kilometres—that is, about the ten-thousandth part of the quantity itself. This degree of precision is far beyond any we can hope to reach in the solar parallax. The other element which enters into consideration is the time required for light to pass from the sun to the earth. Here no such precision can be attained. Both direct and indirect methods are available. The direct method consists in observing the times of some momentary or rapidly varying celestial phenomenon, as it appears when seen from opposite points of the earth's orbit. The only phenomena of the sort available are eclipses of Jupiter's satellites, especially of the first. Unfortunately these eclipses are not sudden but slowly changing phenomena, so that they cannot be observed without an error of at least several seconds, and not infrequently important fractions of a minute. As the entire time required for light to pass over the radius of the earth's orbit is only about 500 seconds, this error is fatal to the method. The indirect method is based upon the observed constant of aberration or the displacement of the stars due to the earth's motion. The minuteness of this displacement, about 20-50'', makes its precise determination an extremely difficult matter. The most careful determinations are affected by systematic errors arising from those diurnal and annual changes of temperature, the effect of which cannot be wholly eliminated in astronomical observation; and the recent works of Vennes and of Struve have introduced a new element of uncertainty into the determination. In consequence of it, the values of \( \pi = 8.806°. \) These last values agree very closely with a determination made by Gill at the Cape of Good Hope, and most other recent determinations give values exceeding 20.50'', while it is probable that the value exceeds 20°. So far as the results of direct observation are concerned may, for the present, be fixed at 20.52''. The corresponding value of the solar parallax is 8.782°.

In addition to the doubt thrown on this result by the discrepancy between various determinations of the constant of aberration, it is sometimes doubted whether the latter constant necessarily expresses with entire precision the ratio of the velocity of the earth to the velocity of light. While the theory that it does seems highly probable, it cannot be regarded as absolutely certain.

III. The combined mass of the earth and moon admits of being determined by its effect in changing the position of the plane of the orbit of Venus. The motion of the node of this plane is found with great exactness from observations of the transits of Venus. So exact is the latter determination that, were there no weak point in the subsequent parts of the process, this method would give far the most certain result for the solar parallax. Its weak point is that the apparent motion of the node depends partly upon the motion of the ecliptic, which cannot be determined with equal precision. The derivation of the distance of the sun by it is of such interest from its simplicity that we shall show the computation.

From the observed motion of the node of Venus, as shown by the four transits of 1761, 1769, 1867, and 1884, it is found:

\[ \text{Mass of (earth+moon)} = \frac{\text{Mass of sun}}{332000} \]
PARALLELISM—PARALYSIS

In gravitational units of mass, based on the metre and second as units of length and time,

Log. earth's mass = 14.60052

moon's mass = 12.6895.

The sum of the corresponding numbers multiplied by 332600 gives

Log. sun's mass = 20.12773.

Putting \( a \) for the mean distance of the earth from the sun, and \( n \) for its mean motion in one second, we use the fundamental equation

\[
\alpha^2 = M_{0}n^2 = \frac{2\pi}{31558149}\log n = 7.39907
\]

Putting \( n \) for the mean motion in one second, we use the fundamental equation

\[
\alpha^2 = M_{0}n^2 = \frac{2\pi}{31558149}\log n = 7.39907
\]

The denominator of the fraction being the number of seconds in the sidereal year. Then, from the formula

\[
\alpha^2 = M_{0}n^2 = \frac{2\pi}{31558149}\log n = 7.39907
\]

we find

Log. \( a \) in metres = 11.17653

Log. equiv. rad. = 3.80470

Sine \( \theta \)'s eq. hor. par. = 5.62817

Sun's eq. hor. par. = 8.762".

IV. The determination of the solar parallax through the parallactic inequality of the moon's motion also involves two elements—one of observation, the other of purely mathematical theory. The inequality in question has its greatest negative value near the time of the moon's first quarter, and the greatest positive value near the third quarter. Meridian observations of the moon have been heretofore made by observing the transit of its illuminated limb. At first quarter its first limb is illuminated; at third quarter, its second limb. In each case the results of the observation may be systematically in error, not only from the uncertain diameter of the moon, but in a still greater degree from the varying effect of irradiation and the personal equation of the observers. The theoretical element is the ratio of the parallactic inequality to the solar parallax. The determination of this ratio is one of the most difficult problems in the lunar theory.

Accepting the definitive result of the researches of E. W. Brown, the value of the solar parallax derived by this method is about

\[ \theta = 8.773". \]

V. The fifth method is, as we have said, the most uncertain

Motion of Earth.

is

\[ \theta = 8.818". \]

The following may be taken as the most probable values of the solar parallax, as derived independently by the five methods we have described:

From measures of parallax . . . 8.802"

velocity of light . . . 8.781"

mass of the earth . . . 8.762"

par. ineq. of moon . . . 8.773"

lunar equation . . . 8.816"

The question of the possible or probable error of these results is one on which there is a marked divergence of opinion among investigators. Probably no general agreement could now be reached on a statement more definite than this; the last result may be left out of consideration, and the value of the solar parallax is probably contained between the limits 8.776" and 8.804." The most likely distance of the sun may be stated in round numbers as 93,000,000 miles. (S. N.)

PARALLELISM, PSYCHOLOGICAL, in psychology, the theory that the conscious and nervous processes vary concomitantly whether or not there be any causal connexion between them; in other words "that modifications of consciousness emerge contemporaneously with corresponding modifications of nervous process" (Stout). The theory is the third possible alternative in considering the relation between mind and body, the others being interaction and one-sided action (e.g. materialism). It should be observed that this theory is merely a statement, not an explanation. (See Psychology.)

PARALLEL MOTION, a form of link-work invented by James Watt, and used in steam-engines (see Steam-Engine, § 88), to connect the head of the piston rod, moving up and down in a vertical path, with the end of the beam, moving in the arc of a circle. An ordinary form is shown diagrammatically in figure. MN is the path in which the piston-rod head, or crosshead, as it is often called, is to be guided. ABC is the middle line of half the beam, C being the fixed centre about which the beam oscillates. A link BD connects a point in the beam with a radius link ED, which oscillates about a fixed centre at E. A point P in BD, taken so that BP : DP :: EN : CM, move in a path which oscillates very closely with the straight line MN. Any other point F in the line CF or CP produced is made to copy this motion by means of the links AF and FG, parallel to BD and AC. In the ordinary application of the parallel motion a point such as F is the point of attachment of the piston-rod, and P is used to drive a pump-rod. Other points in the line CP produced are occasionally made use of by adding other links parallel to AC and BD.

Watt's linkage gives no more than an approximation to straight-line motion, but in a well-designed example the amount of deviation need not exceed one-fourth-thousandth of the length of stroke. It was for long believed that the production of an exact straight-line motion by pure linkage was impossible, until the problem was solved by the invention of the Peaucelle cell. (See also Mechanics: Applied Mechanics, §§ 77, 78.)

PARALLELS, in siegecraft, a term used to express the terrors drawn by besiegers in a generally parallel direction to the front of the besieged (Gr. paraleles, parallel). Parallels are employed along with "zigzag approaches" in the "formal attack" or siege proper. They are traced in short zigzag lengths (the prolongation of each length falling clear of the hostile works), in order to avoid enfilade; but their obliquity is of course made as slight as is consistent with due protection in order to save time and labour. The "first parallel" is opened at a convenient distance from the fortress, by numerous working parties, who dig (under cover of night) a continuous line of entrenchments facing the point or points of attack. Zigzags are next dug to the rear (when necessary) to give sheltered access to the parallel, and from this new zigzags are pushed out towards the defenders, to be connected by a "second parallel," and so on until finally a parallel is made sufficiently close to the fortress to permit of an assault over the open, the parallels becoming stronger and more solid as they approach to closer range. This system of parallels provides, within range of the defenders' weapons, shelter in which the besieger can safely mass men and material for the prosecution of the attack. Parallels and approaches are constructed either by ordinary "trench work," executed simultaneously by a large number of men strung out along the intended line, or by "sapping" in which one trained "sapper" as it were, burrows a trench in the required direction, others following him to widen and improve the work.

PARALUS and SALAMINIA, the name of two ancient Athenian triremes used for sacred embassies, the conveyance of despatches and tribute money, the transportation of state criminals, and as flags in time of war. It is probable that a third vessel of the same kind (called Delia) was used exclusively for Delian embassies, although it has been identified by some with the Salaminia.

PARALYSIS, or Palsy (from Gr. παραλίσθ, to relax; Wycliffe has palsy, and another old form of the word is parley), a term which in its wider acceptance indicates abolition of motor, sensory, sensorial or vaso-motor functions, but in medical nomenclature is usually restricted to the loss or impairment of voluntary muscular power. Paralysis is to be regarded rather as a symptom than a disease per se; it may arise (i) from injury
PARALYSIS

763

or disease of nervous and muscular structures, and is then termed organic paralysis; or (2) from purely dynamic disturbances in the nervous structures of the brain, which produce overvoltage or paralytic movement. The latter is functional motor paralysis, a symptom common in certain neuroses, especially hysteria.

For general paralysis of the insane, see INSANITY.

Whether the loss of motor power be functional or organic in origin, it may be generalized in all the muscles of the body, or localized to one or many. The different forms of paralysis of the voluntary muscles which may arise from organic disease can be understood by a consideration of the motor path of voluntary impulses from brain to muscle. There are two neural segments in this path, an upper cerebral and a lower spinal; the former has its departure platform in the brain and its terminus in the whole of the anterior grey matter of the spinal cord, whence issues the lower spinal segment of the motor path to the muscles. The nerve fibres of the upper cerebral segment are prolongations of the large psycho-motor cells; the nerve fibres of the lower segment are prolongations by the anterior roots and motor nerves of the large cells in the grey matter of the cord. Disease or destruction of any part of the upper segment will give rise to loss of voluntary power, for the influence of the mind on the muscles is removed in proportion to the destruction of this efferent path (see diagram in NEUROPATHOLOGY). Disease or destruction of the lower spinal segment causes not only loss of voluntary power but an atrophy of the muscles themselves. Paralysis may therefore be divided into three great groups: (1) loss of voluntary power without muscular wasting except from disuse, and without electrical changes in the muscles due to injury or disease of the upper cerebral segment of the motor path of volition; (2) loss of muscular power with wasting and electrical changes in the muscles due to disease or injury of the lower spinal segment formed by the cells of the grey matter of the spinal cord, the anterior roots and the peripheral motor nerves; (3) primary wasting of the muscles.

The more common forms of paralysis will now be described.

1. Hemiplegia, or paralysis affecting one side of the body, is a frequent result of apoplexy (q.v.); there is loss of motion of the tongue, face, trunk and extremities on the side of the body opposite the lesion in the brain. In a case of severe complete hemiplegia both arm and leg are powerless; the face is paralysed chiefly in the lower part, while the upper part moves almost as well as on the unparalysed side, and the eye can be shut at will, unlike peripheral facial paralysis (Bell’s palsy). The tongue when protruded deviates towards the paralysed side, and the muscles of mastication contract equally in ordinary action, although difficulty arises in eating, from food accumulating between the cheek and gums on the paralysed side. Speech is thick and indistinct, and when there is right-sided hemiplegia in a right-handed person, there may be associated various forms of aphasia (q.v.), because the speech centres are in the left hemisphere of the brain. Some muscles are completely paralysed, others are merely weakened, while others, e.g. the trunk muscles, are apparently unaffected. In many cases of even complete hemiplegia, the motor nerves to the face in children take about a few weeks or months, and is generally first indicated by return of movement in the muscles which are habitually associated in their action with those of the opposite unparalysed side; thus, movement of the leg returns first at the hip and knee joints, and of the arm at the shoulder and elbow, although the hand may remain motionless. The recovery however in the majority of cases is only partial, and the sufferer of hemiplegia is left with a permanent weakness of one side of the body, often associated with contracture and rigidity, giving rise to a characteristic gait and attitude. The patient in walking leans to the sound side and rounds the affected leg from the hip, the inner side of the toe of the boot scraping the ground as it is raised and advanced. The arm is adducted at the shoulder, flexed at the elbow, wrist and fingers, and resists all attempts at extension. According to the part of the brain damaged variations of paralytic symptoms may arise; thus occasionally the paralysis may be limited more or less to the face, the arm or the leg. In such case it is termed monoplegia, a condition sometimes arising from cerebral tumour. Occasionally the face is paralysed on one side and the arm and leg on the other side; this condition is termed alternate hemiplegia, which is due to the fact that the disease has damaged the motor path from the brain to the arm and leg before it has crossed over to the opposite side, whereas the path to the face muscles is damaged after it has crossed. In rare cases both leg, arm and face on one side may be paralysed—triplegia; or all four limbs—bilateral hemiplegia. Infantile spastic paralysis, infantile diplegia, or as it is sometimes called Little’s disease, is a birth palsy caused by injury from protracted labour, the use of forceps or other causes. The symptoms are generally not observed until long after birth. Convulsions are common, and the child is unable to sit up or walk long after the age at which it should do so.

Paraplegia is a term applied to paralysis of the lower extremities; there are many causes, but in the great majority of instances it arises from a local or general disease or injury of the spinal cord. A localized transverse myelitis will interrupt the motor and sensory paths which connect the brain with the spinal grey matter below the lesion, and when the destruction is complete, motor and sensory paralysis in all the structures below the lesion occurs; thus fracture, dislocation and disease of the spinal column (e.g. tubercular caries, syphilitic disease of the membranes, localized tumours and haemorrhages) may cause compression and inflammatory softening, and the result is paralysis of the voluntary muscles, loss of sensation, loss of control over the bowel and bladder, and a great tendency to the development of bed-sores. The muscles do not waste except from disuse, nor undergo electrical changes unless the disease affects the spinal grey matter or roots as well as the cerebral path. When it does so, as in the case of acute spreading myelitis, the symptoms are usually more severe and the outlook is more grave.

In cases of focal myelitis from injury or disease, recovery may take place and the return of power and sensation may occur to such an extent that the patient is able to walk long distances; this is the most common terminating in cases of localized disease or injury of the spinal cord often takes place by keeping the patient on his back in bed, daily practising massage and passive movements, and so managing the case as to avoid bedsores and septic inflammation of the bladder—the two dangerous complications which are liable to arise.

2. Paralysis may result from acute inflammatory affections of the spinal cord involving the grey and white matter—myelitis (see Neuropathology).

Infantile or Essential Paralysis.—This is a form of spinal paralysis occurring with frequency in young children; in Scandinavian countries the disease is prevalent and sometimes assumes an epidemic form, whereby one is led to believe that it is due to an infective organism. The names infantile and essential paralysis were given before the true nature of the disease in the spinal cord was known; precisely the same affection may occasionally occur, however, in adults, and then it is termed adult spinal paralysis. The medical name for this disease is acute anterior poliomyelitis (Gr. ἀνterior, grey, and μυελος, marrow), because the anterior grey matter of the spinal cord is the seat of acute inflammation, and destruction of the spinal motor nerve path to the muscles. The extent of the spinal grey matter affected and the degree of destruction of the motor nerve elements which ensues determine the extent and permanency of the paralysis. The term atrophic spinal paralysis is sometimes employed as indicating the permanent wasting of muscles that results.

Infantile paralysis often commences suddenly, and the paralysis may not be observed until a few days have elapsed; the earliest symptoms noticeable are fever, convulsions and sometimes vomiting; and, if the child is old enough, it may complain of pains or numbness or tingling in the limb or limbs which are subsequently found to be paralysed. It is characteristic, however, of the disease that there is no loss of sensation...
PARALYSIS

in the paralysed limb. The whole of the limb is not necessarily paralysed, often it is only a group of muscles, and even if the paralysis afflicts both legs or the arm and leg on one side, it generally fails in the same form of distribution as the previously described paraplegia or hemiplegia. The affected muscles rapidly waste and become flaccid, the electrical reactions change, and finally the muscles may cease to respond to electrical stimulation whether of the continuous or interrupted current. In the less severe cases (and they are the most common) only a group of muscles undergo complete paralysis and atrophy, and there is always hope of some return of power in a paralysed limb. Associated with the withered condition of the limb due to the muscular atrophy is an enfeebled circulation, rendering the limb cold, blue and livid; the nutrition of the bones and other parts is involved, so that a limb paralysed in early infancy does not grow and is shorter than its fellow. Deformities arise, some the result of simply failing muscular support; others due to permanent changes in the position of the limbs, for example clubfoot. There is absence of bladder and bowel troubles, and bedsores do not occur; the disease itself is rarely, if ever, fatal. About a month after the onset of the disease, the local trouble of the atrophied muscles should be commenced, and every effort should be made by massage, by suitable positions and passive movements to promote the circulation and prevent deformities in the affected limbs. Should these measures fail, surgical aid should be sought.

Sub-acute and chronic forms of atrophic and spinal paralysis have been described, but some of them were undoubtedly cases of peripheral neuritis.

Wasting Palsy. Progressive Muscular Atrophy.—This is a chronic disease characterized by slow and insidious weakness and wasting of groups of muscles due to disease of the anterior spinal grey matter. It begins mostly in adult life between 25 and 45 years of age, and affects males more than females. In the majority of cases it commences in the upper extremities, and the small muscles of the hand are especially liable to be affected. The palmar eminences of the thumb and little finger, owing to the wasting of the muscles, gradually disappear, and a flat ape-like hand is the result; in extreme cases the small muscles of the hand are atrophied, and a claw-like hand is the result. The muscles which are next most liable to atrophy are those of the shoulder and upper arm, and the atrophy may thence spread to the muscles of the neck and trunk, and the intercostals and even the diaphragm may be affected, causing serious difficulties of respiration. The lower extremities are less often and later affected by wasting. This disease generally runs a slow and progressive course; it may however be years before it spreads from the hand to the arm, and a period of arrest may occur before other muscles become involved. A characteristic feature of the disease is fibrillary twitching of the wasting muscles. The electrical excitability of the muscles is diminished rather than changed, except where the wasting is very extreme, when a partial reaction of degeneration may be obtained. Sensation is unaffected, as the disease is limited to the motor cells of the anterior grey matter (see Neuropathology). There is no affection of the bowel or bladder. Death usually occurs from intercurrent diseases, such as pneumonia, diabetes, and broncho-pneumonia. Some patients die owing to failure of the respiratory muscles; others from the disease spreading to the medulla oblongata (the bulb of the brain) and causing bulbar paralysis. The chronic morbid process leading to decay and destruction of the spinal motor cells which is the essential pathological feature of this disease is generally accompanied, and sometimes preceded, by degeneration of the path of voluntary impulses from the brain. It is then called amyotrophic lateral sclerosis, a rapid form of progressive muscular atrophy.

Bulbar Paralysis.—A number of different morbid conditions may give rise to a group of symptoms, the principal features of which are paralysis of the muscles concerned in speech, swallowing, phonation and mastication. These symptoms may arise suddenly from vascular lesions or inflammatory processes, which involve the nucle of origin of the cranial nerves supplying the muscles of the tongue, lips, pharynx and larynx. But there is also a slow degenerative insidious progressive bulbar paralysis affecting both sexes pretty equally; it came on between 40 to 60 years of age, and the cause is unknown. Slight indistinctness of speech, especially in the utterance of consonants requiring the elevation of the tip of the tongue to the dental arch and palate, is usually the first symptom. Later the explosive lip sounds are indistinctly uttered; simultaneously, owing to paralysis of the soft palate, the speech becomes nasal in character and sooner or later, associated with this difficulty of speech, there is a difficulty of swallowing, partly because the tongue is unable to convey the food to the back of the mouth, and it accumulates between the cheeks and gums. Moreover the pharyngeal muscles are unable to seize the food and start the process of swallowing on account of the paralysis of the soft palate; liquids are apt to regurgitate through the nostrils, the patient must therefore be nourished with soft semi-solid food. As the disease proceeds, the difficulty of speech and swallowing is increased by the affection of the laryngeal muscles; the pitch of the voice is lowered and the glottis is imperfectly closed by the deglutitive movements, consequently there is difficulty of passing liquids and food to pass into the larynx and set up fits of coughing, which, however, are ineffective. Later the muscles of mastication are affected and the disease may extend to the respiratory centre, giving rise to attacks of dyspnoea. The intellectual faculties are as a rule unimpaired, although the facial expression and the curious emotional mobility of the countenance, with a tendency of the patient to burst into tears or laughter, would suggest weak-mindedness. Whilst the lower half of the face is strikingly affected, the upper half retains its normal expression and power of movement. This disease is usually rapidly fatal, since it affects the vital centres, and liability to broncho-pneumonia excited by the entrance of food into the air passages is also a constant danger in the later stages.

Bulbar Paralysis without Anatomical Change.—This condition is also termed "myasthenia gravis"; it differs from acute and chronic bulbar disease by the absence of muscular atrophy, by normal electrical excitability of the muscles, by a marked tendency to the presentment of the paralysis by fatigue, and by considerable remissions of the symptoms. The bulbar symptoms are the most prominent, but all voluntary muscles are more or less affected, especially the eye-muscles. It is a rare disease affecting both sexes equally at almost any age, the causes and pathology of which are unknown.

3. Paralysis resulting from disease or injury of the motor path to the muscles in the peripheral nervous system.

Neuritis.—Paralysis may arise in a muscle, a group of muscles, a whole limb, the lower extremities, or there may be a generalized paralysis of voluntary muscles as a result of neuritis. A typical example of neuritis giving rise to paralysis owing to inflammatory swelling and compression is afforded by the facial nerve; this purely motor nerve as it passes out of the skull through a narrow bony passage is easily compressed and its function interfered with, causing a paralysis of the whole of one side of the face and Bell's Palsy. Exposure to a cold draught in a person with rheumatic diathesis is a frequent cause. As an example of the mechanical compression producing paralysis, crutch palsy may be cited; it is the result of continuous compression if the musculo-spiral nerve as it winds round the bone of the upper arm.

Lead poisoning may give rise to a localized neuritis affecting the posterior inter-osseous nerve, especially in painters and in those whose occupations necessitate excessive use of the extensors of the forearm; the result is wrist drop or lead palsy.

Sciatica is a painful inflammatory condition of the sciatic nerve, in which there may be weakness of the muscles; but inability to move the limb is more on account of the pain it causes than on account of paralysis of the muscles. Exposure to cold and wet, e.g. sitting on a damp seat, may lead to sciatica in a gouty or rheumatic person.

Multiple neuritis is a painful generalized inflammation of the peripheral nervous system and arises in many toxic conditions.
of the blood; among the most important are lead, arsenic and chronic alcohol poisoning. It also occurs in diabetes, diphtheria, beri-beri and other conditions (see NEUROPATHOLOGY). A short description of the commonest form will be given. It occurs in chronic alcoholism and especially in women, and most frequently due to a combination of a septic absorption from some internal disease and the abuse of alcohol. In a marked case the patient may suffer from paraplegia, but it is distinguished from the paraplegia of spinal disease by the fact that there is loss of control of the sphincters only when there is associated dementia, and that instead of the limbs being insensible they are extremely painful on deep pressure. There is wasting of the muscles, and electrical changes in them; frequently there is anaesthesia and analgesia of the skin, which takes a stocking-like distribution. In severe cases the upper limbs may be affected, and all the muscles of the body are more or less liable to be paralysed—even the heart may suffer. The mental condition in such a severe case is usually quite characteristic; there is delirium, the patient is the subject of hallucinations and delusions; there is loss of knowledge of time and place, and illusions of personal identity. A constant symptom is the memory of recent events, while those of early life are easily recollected.

Paralyses—termed medically muscular dystrophies—may arise from a primary atrophy of muscle apparently independent of any discoverable change in the nervous system, but due to a congenital developmental defect of the muscles. Heredity plays an important part in the incidence of these diseases, members of the same family being affected with the same type of disease, and at the same period of life. There may be a tendency in a family to the affection of one sex and not the other; on the other hand, children of both sexes may suffer in the same family. It is curious that the majority of cases are males, and that it is transmitted by women who are not themselves its subjects. Many different clinical types have been described based upon the age of onset, the groups of muscles first affected, and the presence or absence of apparent hypertrophy; they are however all varieties of one affection, and in a case where there is an apparent enlargement of muscles there is really atrophy of the contractile muscle fibres and overgrowth of fat and interstitial fibrous tissue; consequently this form of the disease is called pseudo-hypertrophic paralysis.

The muscular dystrophies may be divided into two groups according to the period of life in which the malady manifests itself: (1) Those occurring in childhood; (2) those occurring in youth or adult life. In the first group the muscles may be atrophied or apparently hypertrophied. A progressive atrophy of muscles associated with progressive weakness and various disabilities of movement is soon recognized in the relation of cause and effect; but the parents whose first child looks like an infant Hercules, with abnormally large calves and buttocks, cannot for some time appreciate any connexion of this condition with a muscular weakness which is manifested in various ways. The child stands with its feet widely separated; it waddles along rather than walks; it falls easily and rises with difficulty, having to use the hands to push against the floor; it then rests one hand on the knee, and then the other hand on the other knee, and clumbs, as it were, up its own thigh in order to assume the erect posture. In this pseudo-hypertrophic form of paralysis the outlook is very grave, and there is little hope of the patient reaching adult life.

Paralysis agitans, Shaking Palsy or Parkinson's Disease is a chronic progressive disease of the nervous system occurring late in life, and characterized by weakness, tremors and stiffness of the muscles associated with a peculiar attitude and gait. The first sign of the disease is weakness followed by tremor of one hand; this consists of continuous movements of the thumb and forefinger as in rolling a pill, or of movements of the hand like beating a tom-tom; then the other hand is affected, and later there is tremor at the ankle. In some cases there is a continual nodding movement of the head. These tremors are at the rate of five per second and cease during sleep. The attitude and gait are very characteristic; the head is bent forward, and the patient in beginning to walk takes slow steps, which soon become short and quick as if he were running after his centre of gravity. The intellect is clear and in marked contrast to the mask-like expression. This disease lasts for years, and but little progress in the way of treatment, except passive movements of the limb to prevent contracture.

Treatment.—There are certain general principles in the treatment of all forms of paralysis which may be summarized as follows.

1. Rest in bed and attention to the vital functions of the body, the head's action, the respiratory functions, nutrition and excretion.

2. The disease is the hazard due to the administration of drugs and stimulants. As regards the respiratory sources of the dangers of paralysis is an intercurrent pneumonia—sometimes unavoidable, often due, however, to attempts to give nourishment to a patient in an insensible state, with the result that some of the fluid enters the bronchial tubes, when either the reflex protective coughing is not excited or is ineffectual. Attention to the bowels and bladder is most important. A purge at the onset of paralysis is indicated when the pulse is full and of high tension, and the regular action of the bowels is necessary in all conditions. Retention of urine should be carefully avoided, if necessary by the passing of a catheter, but too much emphasis cannot be laid upon the importance of adopting aseptic precautions to avoid infection of the bladder. Syrup of iron is probably the best general aliment for all paralysed patients, and precautions taken to keep the skin of all exposed parts of the body clean; the back should be laved with eau-de-Cologne or spirit to harden the skin. Any sign of a red spot on the back or buttock may be an indication of a paralysed side. A warning note of the possibility of a bedsores; zinc powder or ointment treatment should be used and the effect of pressure on the part be removed if possible by change of posture and by the use of a water-bed. It is important to cover all warm bottles with flannel, for owing to insensibility large blisters, which heal with difficulty, may result. In cases of paralysis the legs should be covered with warm woollen hand-knit stockings, and a cradle employed to protect the feet from the continuous weight of the bed-clothes, a fruitful source of foot drop.

2. As soon as the acute symptoms have passed off passive movement and massage may be employed with advantage; in some cases electrical treatment is indicated; but as a rule, especially in children, electrical treatment offers the disadvantage of being painful and painful and cannot accommodate those who have become partially paralysed. Passive movements of the limbs, massage and passive movements. When the passive movements are being made the patient should be instructed by the operator to will the movement which he is performing, and thus try to re-establish the connection of the brain with the muscles through the point of interruption or by a new path if that is not possible.

PARAMARIBO—PARAMENT

PARAMARIBO, the capital of Dutch Guiana or Surinam (see Guiana), in 5° 44' 30" N., 55° 12' 54" W., 20 m. from the sea on the right bank of the Surinam, here a tidal river nearly a mile broad and 18 ft. deep. Pop. (1905), 33,821. Built on a plateau about 16 ft. above low-water level, Paramaribo is well-drained, clean and in general healthy. The straight canals running at right angles to the river, the broad, straight tree-planted streets, the spacious squares, and the solid plain public buildings would not be unworthy of a town in the Netherlands.

The Indian village of Paramaribo became the site of a French settlement probably in 1640, and in 1650 it was made the capital of the colony by Lord Willoughby of Parham. In 1693 it was still only a "cluster of twenty-seven dwellings, more than half of them grog-shops," but by 1700 it counted more than a thousand houses. The town was partly burned down in 1821, and again in 1832.

PARAMEOCUM, O. F. Müller, (often misspelt Paramaeicum, Paramoecium), a genus of aspirotrous ciliate Infusoria (95 s.), characterized by its slipper-like shape, common in infusions, especially when they contain a little animal matter. It has two dorsal contractile vacuoles, each receiving the mouths of five radiating canals from the inner layer of the ectosarc, and a large ovoid megalanecus, and one or two micronuclei. From its abundance, the ease with which it can be cultivated and observed, its relatively simple structure and adequately large size (1/20 mm.), it is most frequently selected for elementary study and demonstration, as well as for purposes of research.

PARAMENT (Fr. parament, from Late Lat. paramentum, adornment, para, to prepare, equip), a term applied by ancient writers to the hangings or ornaments of a room of state.
PARAMOUNT—PARANOIA

PARAMOUNT (Anglo-Fr. paramount, up above, par à mont, up or on top of the mountain), superior, supreme, holding the highest authority, or being of the greatest importance. The term was first used, as a term of feudal law, of the lord, the "lord paramount," who held his fief from no superior lord, and was thus opposed to "mesne lord," one who held from a superior. To those who held their fiefs from one who was not a "lord paramount" was given the correlative term "paravall, par à sol, in the valley. The word was confused by English lawyers with "avail," help, assistance, profit, and applied to the actual working tenant of the land, the lowest tenant or occupier.

PARANÁ, a state of southern Brazil, bounded N. by São Paulo, E. by the Atlantic, S. by Santa Catharina and the republic of Argentina, and W. by Matto Grosso and the republic of Paraguay, with the Paraná river as its western boundary line. Area, 35,451 sq. m.; pop. (1890), 249,491; (1900), 327,316. It includes two dissimilar regions—a narrow coastal zone, thickly wooded, swampy, and semi-tropical in character, and a high plateau (2500 to 3000 ft.) whose precipitous, deeply eroded eastern escarpments are known as the Serra do Mar, or Serra do Cubatão. The southern part of the state is densely forested and has large tracts of Paraguay tea (Ilex paraguayensis), known in Brazil as herva maté, or mate. The plateau slopes westward to the Paraná river, is well watered and moderately fertile, and has a remarkably uniform climate of a mild temperate character. The larger rivers of the state comprise the Parana panema and its tributaries the Cinza and Tibagy, the Ivery, Piquiry, Jeyu-guassú, and the Iguassú with its principal tributary the Rio Negro. The Paranapanema and a small tributary, the Itarare, form the boundary line with São Paulo west of the Serra do Mar, and the Iguassú and Negro, the boundary line with Santa Catharina and Argentina—both streams having their sources in the Serra do Mar and flowing westward to the Paraná. The other streams have shorter courses, and are obstructed by falls and rapids. Twenty miles above the mouth of the Iguaçu the Paraná or Parana has, at its broadest, but into twenty or more falls separated by rocks and islands, and surrounded by a wild, unsettled and wooded country. The falls are reached by occasional light-draught steamers on the Paraná between Posadas (Argentina) and the mouth of the Iguaçu, and thence by canoe to the vicinity of the falls. The surface of the plateau is undulating and the greater part is adapted to agricultural and pastoral purposes. There are two railway systems—the Parana to Curityba (69 m.) with an extension to Ponta Grossa (118 m.) and branches to Rio Negro (55 m.), Porto Amazonas (6 m.) and Antonina (10 m.); and the São Paulo & Rio Grande, which crosses the state from north-east to south-west from Porto União da Victoria, on the Iguaçu, to a junction with the Sorocabana line of São Paulo at Itarare. The upper Paraná is navigable between the Guayrá, or Sete Quedas, and the Urubu-pungu Falls. The chief export of Paraná is Paraguay tea (a forest product). The large foreign element in the population owing to the immigrant colonies established on the uplands, and considerable progress has been made in small farming and education. Besides the capital, Curityba, the principal towns are Paranaguá; Antonina, at the head of the Bay of Paranaguá, with a population of 7739 in 1890; Campo Largo, 20 m. west of Curityba (pop. 10,642 in 1890); Castro, N.W. of the capital on the São Paulo & Rio Grande line (pop. of the municipality, 10,310 in 1890); and Ponta Grossa (pop. of municipality, 4774 in 1890), north-west of Curityba at the junction of the two railway systems of the state.

Paraná was settled by gold prospectors from São Paulo and formed part of that captaincy and province down to 1853, when it was made an independent province. The first missions of the Jesuits on the Paraná were situated just above the Guayrá Falls in this state and had reached a highly prosperous condition when the Indian slave hunters of São Paulo (called Mamelucos) swept down and compelled them to leave their settlements and emigrate in mass to what is now the Argentine territory of Misiones. The ruins of their principal mission, known as Ciudad Real, are overgrown with forest.

PARANÁ, a city and port of Argentina, capital of the province of Entre Rios, and the see of a bishopric, situated on the left bank of the Paraná river, 410 m. by navigable channels (about 240 m. direct) N.W. of Buenos Aires. Pop. (1893), 24,261; (1904, estimate), 27,000. The city occupies a gently rolling site 120 ft. above the river and about 2 m. from its riverside port of Baja Grande, with which it is connected by railway, tramway and highway. It is classed as a seaport, and ocean-going vessels of not over 12 ft. draught can ascend to Baja Grande. There is also a daily ferry service across the river to Santa Fé (7 m. distant), which is connected by railway with Rosario and Buenos Aires. Paraná is also the western terminus of a provincial railway system, which connects with Concepción and Concordia, on the Uruguay river, and with other important towns of the province. The mean annual temperature is about 66° F. and the climate is bracing and healthful. Its port of Baja Grande, on the river shore below the bluffs, has the custom-house and a fine wharf for the accommodation of the Entre Rios river and railway craft. Paraná was founded in 1730, by colonists from Santa Fé and was at first known as Baja (a landing place). It was made the capital of the province by General Mansilla in 1821 (Concepción had previously been the capital), but in 1861 General Urquiza restored the seat of government to Concepción, where it remained until 1882, when Paraná again became the capital. Paraná was also the capital of the Argentine Confederation from 1852 to 1861.

PARANÁGUÁ, a seaport of the state of Paraná, Brazil, on the southern shore of the Bay of Paranaguá, about 9 m. from the bar of the main channel. Pop. of the municipality (1890), 11,794, of which a little more than one half belonged to the town. Paranaguá is the principal port of the state, and is a port of call for steamers in the coastwise trade. It is the coastal terminus of a railway running to Curityba, the capital (69 m.), with extensions to other island towns and a branch to Antonina, at the mouth. In the same year (1890) the town of Paranaguá was founded.

The Bay of Paranaguá opens into the Atlantic in lat. 25° 32' S. through three channels and extends westward from the bar about 10 m. It is irregular in outline, receives the waters of a large number of small streams, and is comparatively shallow. Light-draught steamers can ascend to Antonina at the head of the bay. The broad entrance to the bay, which is the gateway to the state of Paraná is nearly filled by the large Ilha do Mel (Honey Island) on which stands an antiquated fort commanding the only practicable channel.

PARANDHAR, a hill fort of British India, in Poona district, Bombay, 4472 ft. above the sea, 20 m. S.E. of Poona: pop. (1901), 944. It figures repeatedly in the rising of Sivaji against the Mahommedans, and was the favourite stronghold of the Peshwas whenever the despised city of Poona was threatened. It gave its name to a treaty with the Mahrattas, signed in 1776 but never carried into effect. It is now utilized as a sanatorium for British soldiers.

PARANOIA (Gr. παρά, beyond, and νοεῖν, to understand), a chronic mental disease, of which systematized delusions with or without hallucinations of the senses are the prominent characteristics. The delusions may take the form of ideas of persecution or of grandeur and ambition; these may exist separately or run concurrently in the same individual, or they may become transformed in the course of the patient's life from a persecutory to an ambitious character. The disease may begin during adolescence, but the great majority of the subjects manifest no symptoms of the affection until full adult life.

The prominent and distinguishing symptom of paranoia is the delusion which is gradually organized out of a mass of original but erroneous beliefs or convictions until it forms an integral part of the ordinary mental processes of the subject and becomes fused with his personality. This slow process of the growth of a false idea is technically known as "systematization,"
and the resulting delusion is then said to be "systematized." As such delusions are coherently formed there is no manifest mental confusion in their expression. Notwithstanding the fixity of the delusion it is subject in some cases to transformation which permits of the gradual substitution of delusions of grandeur for delusions of persecution. It happens also that periods of remission from the influence of the delusion may occur from time to time in individual cases, and it may even happen, though very rarely, that the delusion may permanently disappear.

It is necessary to point out that there is undoubtedly what may be called a paranoid mental constitution, in which delusions may appear without becoming fixed or in which they may never appear. The characteristics of this type of mind are credulity, a tendency to mysticism and a certain aloofness from reality, combined, as the case may be, with timidity and suspicion or with vanity and pride. On such a soil it is easy to understand that, given the necessary circumstances, a systematized delusional insanity may develop.

The term paranoia appears to have been first applied by R. von Kraft-Ebing in 1879 to all forms of systematized delusional insanity. Werner in 1889 suggested its generic use to supplant Wahnsinn and Verrücktheit, the German equivalents of mental states which originally meant, respectively, the delusional insanity of ambition and the delusional insanity of persecution—terms which had become hopelessly confused owing to divergences in the published descriptions of various authors.

The rapid development of clinical study has now resulted in the isolation of a comparatively small group of diseases to which the term is applied and the relegation of other groups bearing more or less marked resemblances to it to their proper categories. Thus, for example, it had formerly been held that acute paranoia was frequently a curable disease. It is now proved that the so-called acute forms were not true paranoias, many of them being transitory phases of E. Kraepelin's dementia praecox, others being terminal conditions of acute melancholia, of acute confusional insanity, or even protracted cases of delirium tremens. While it removes from the paranoia group innumerable phases of delusional insanity met with in patients labouring under secondary dementia as a result of alcoholism or acute insanity, such a statement does not exclude patients who may have had, during their previous life, one or more attacks of some acute mental disease, such as mania, for the paranoid mental constitution may be, though rare, subject to other forms of neurosis. Attempts have been made to fix the relative importance of paranoia by observing the presence or absence of a morbid emotional element in the mind of the subjects, with the object of referring to the group only such cases as manifest a purely intellectual disorder of mind. Though in some cases of the disease the mental symptoms may, at the time of observation, be of a purely intellectual nature, the further back the history of any case is traced the greater is the evidence of the influence of preceding emotional disturbances in moulding the intellectual peculiarities. Indeed it may be said that the fundamental emotions of vanity or pride and of fear or suspicion are the groundwork of the disease. We are justified therefore in ascribing the intellectual aberrations which are manifested by delusions, in part at least, to the preponderating influence of morbid emotions which alter the perceptive and apereceptive processes upon which depend the normal relation of the human mind to its environment. Although, generally speaking, paranoiae manifest marked intellectual clearness and a certain amount of determination of character in the exposition of their symptoms and in their manner of reacting under the influence of their delusions, there is, without any doubt, an element of original abnormality in their mental constitution. Such a mental constitution is particularly subject to emotional disturbances which find a favourable field of operation in an innate mysticism allied with credulity which is impervious to the rational appeal of the intellect. In those respects the paranoid presents an exaggeration of, and a departure from, the psychical constitution of normal individuals, who, while subject both to emotion and to mystical thought, retain the power of correcting any tendency to the predominance of these mental qualities by an appeal to reality. It is just here that the paranoiac fails, and in this failure lies the key to the pathological condition. For the present the question as to whether this defect is congenital or acquired owing to some superimposed pathological condition cannot be answered. However that may be, it is frequently ascertained from the testimony of friends and relatives that the patients have always been regarded as " queer," strange, and different from other people in their modes of thought. It is usually stated that nervous or mental diseases occur in the family histories of over 50% of the subjects of this affection.

Paranoia is classified for clinical purposes according to the form of delusion which the patients exhibit. Thus there are described the Persecutory, the Litigious, the Ambitious and the Amarytoid types. It will be observed that these divisions depend upon the prevalence of the primary emotions of fear or suspicion, pride or vanity and love.

According to V. Magnan, the course of paranoia is progressive, and each individual passes through the stages of persecution and ambition successively. Many authorities accept Magnan's description, which has now attained to the distinction of a classic, but it is objected to by others on the ground that many cases commence with delusions of ambition and manifest the same symptoms unchanged during their whole life, while other patients suffering from delusions of persecution never develop the ambitious form of the disease. Against these arguments Magnan and his disciples assert that the relative duration of the stages and the relative intensity of the symptoms vary widely, so that in the first instance the persecutory stage may be so short or so indefinite in its symptoms as to escape observation; and that in the second instance the persecutory stage may be so prolonged as within the short compass of a human life to preclude the possibility of the development of an ambitious stage. As however there exist types of the disease which, admittedly, do not conform to Magnan's progressive form it will be more convenient to adopt the ordinary description here.

1. Persecutory Paranoia.—This form is characterized by delusions of persecution with hallucinations of a painful and distressing character. In predisposed persons there is often observed an anomaly of character dating from early life. The subjects are of a retiring disposition, generally studious, though not brilliant or successful workers. They prefer solitude to society of their fellows and are apt to be introspective, set in their ways, analytical or given to unusual modes of thought or literary pursuits. Towards the commencement of the insanity the patients become gloomy, preoccupied and irritable. Suspicions regarding the attitude of others take possession of their minds, and they ultimately come to suspect the conduct of their nearest relatives. The conversations of friends are supposed by the patient to be interlarded with phrases which, on examination, he believes to contain hidden meanings, and the newspapers appear to abound in veiled references to him. A stray word, a look, a gesture, a smile, a cough, a shrug of the shoulders on the part of a stranger are apt to be misinterpreted and brooded over. The extraordinary prevalence of this imagined conspiracy may lead the patient to regard himself as a person of great importance, and may result in the formation of delusions of ambition which intermingle themselves with the general conceptions of persecution, or which may wholly supplant the persecutory insanity.

At this juncture, however, it generally happens that hallucinations begin to appear. These, in the great majority of instances, are auditory and usually commence with indefinite noises in the ears, such as ringing sounds, hissing or whistling. Gradually they assume a more definite form until isolated words and ultimately formed sentence are distinctly heard. There is great diversity in the completeness of the verbal hallucinations in different patients. Some patients never experience more than the subjective annoyance of isolated words generally
PARANOIA

of an insulting character, while others are compelled to listen to regular dialogues carried on by unknown voices concerning themselves. A not uncommon form of verbal hallucination is formulated in the complaint of the patients that “all their thoughts are read and proclaimed aloud.” Even more than the enforced listening to verbal hallucinations this “thought reading” distresses the patient and often leads him to acts of violence, for the privacy of his inmost thoughts is, he believes, desecrated, and he often feels helpless and desperate at a condition from which there is no possible escape.

Though some of the subjects do not develop any other form of hallucination, it is unfortunately the lot of others to suffer, in addition, from hallucinations of taste, smell or touch. The misinterpretation of subjective sensations in these sense organs leads to the formulation of delusions of poisoning, of being subjected to the influence of noxious gases or powders, or of being acted on by agencies such as electricity. Such are the persons who take to their food for chemists for analysis; who complain to the police that people are acting upon them injuriously; who hermetically seal every crevice that admits air to their bedrooms to prevent the entrance of poisonous fumes; or who hammer away between the feet of their beds and the floor with the object of insulating electric currents. Such patients obtain little sleep; some of them indeed remain awake all night—for the symptoms are usually worse at night—and have to be content with such snares of sleep as they are able to obtain at odd times during the day. It is obvious that a person tormented and distracted in the way described may at any moment lose self-control and become a danger to the community. But perhaps the most distressing and most distracting of all hallucinations are those which for want of a better name are termed “sexual.” The subjects of these hallucinations, both male and female, under the belief that improper liberties are taken with them, are more clamant and threatening than any other class of paranoids.

During the course of a disease so distressing in its symptoms the patient’s suspicions as to the authors of his persecution vary much in indefiniteness. He often never fixes the direct blame upon any individual, but refers to his persecutors as “they” or a “society” or some corporate body such as “lawyers,” “priests” or “freemasons.” It not infrequently happens, however, that suspicions gradually converge upon some individual or that from an early stage of the disease the patient has, generally under the influence of hallucinations, fixed the origin of his trouble upon one or two persons. When this takes place the matter is always serious from the point of view of physical danger to the inculpated person, especially if the patient is of a violent or vindictive disposition.

The persecutory type of the disease may persist for an indefinite period—even for twenty or thirty years—without any change except for the important fact that remissions in the intensity of the symptoms occur from time to time. These remissions may be so marked as to give rise to the belief that the patient has recovered, but in true paranoia this is hardly ever the case, and sooner or later the persecution begins again in all its former intensity.

1. Ambitious Paranoia.—After a long period of persecution a change in the symptoms may set in, in some cases, and the intensity of the hallucinations may become modified. At the same time delusions of grandeur begin to appear, at first faintly, but gradually they increase in force until they ultimately supplant the delusions of persecution. At the same time the hallucinations of a disagreeable nature fade away and are replaced by auditory hallucinations conformable to the new delusions of grandeur. Undoubtedly, however, this form of paranoia may commence, so far as can be observed, with delusions of grandeur, in which case there is seldom or never a transformation of the personality or of the delusions from grandeur to persecution, although delusions of persecution may engraft themselves or run side by side with the predominant ambitious delusions.

The emotional basis of ambitious paranoia is pride, and every phase of human vanity and aspiration is represented in the delusions of the patients. There is moreover considerably less logical arrangement displayed in the explanations of their beliefs by such patients than in the case of the subjects of persecution. Many of them affect to be the descendants of historical personages without any regard for accurate genealogical detail. They have no compunction in disowning their natural parents or explaining that they have been “changed in their cradles” in order to account for the fact that they are of exalted or even of royal birth. Dominated by such beliefs paranoids have been known to travel all over the world in search of confirmation of their delusions. It is people of this kind who drop into the ears of confusing strangers vague hints as to their exalted origin and kindred, and who make desperate and occasionally alarming attempts to force their way into the presence of princes and rulers. The sphere of religion affords an endless field for the ambitious paranoids and some of them may even aspire to divine authority, but as a rule the true paranoia does not lose touch with earth. The more extravagant delusions of persons who call themselves by divine names and assume omnipotent attributes are usually found in patients who have passed through agitated and at times of a morbid nature such as mania or dementia praecox and are mentally enfeebled.

A not uncommon form of paranoia combining both ambition and persecution is where the subject believes that he is a man of unbounded wealth or power, of the rights to which he is, however, deprived by the machinations of his enemies. These patients frequently obtain the knowledge on which they base their delusions through auditory hallucinations. They are often so troublesome, threatening and persistent in their determination to obtain redress for their imagined wrongs, that they have to be forcibly detained in asylums in the public interest.

On the whole, however, the ambitious paranoia is not troublesome, but calm, dignified, self-possessed, and reserved on the subject of his delusions. He is usually capable of reasoning as correctly and of performing work as efficiently as ordinary people. Many of them, however, while living in society are liable to give expression to their delusions under the influence of excitement, or to behave so strangely and unconventionally on unsuitable occasions as to render their seclusion either necessary or highly desirable.

2. Amatory Paranoia.—A distinguishing feature of this form of paranoia is that the subjects are chivalrous and idealistic in their love. Some of them believe that they have been “mysteriously” married to a person of the opposite sex usually in a prominent social position. The fact that they may have never spoken to or perhaps never seen the person in question is immaterial. The conviction that their love is reciprocated and the relationship understood by the other party is unshakable, and is usually based upon suppositions that to a normal mind would appear either trivial or wholly unreal. The object of affection, if not mythical or of too exalted a position to be approached, is not infrequently persecuted by the admirer, who takes every opportunity of obtruding personally or by letter the evidences of an ardent adoration. The situation thus created can easily become complicated and embarrassing before it is realized that the persistent wooer is insane.

The failure of their schemes or repeated repulses may, in the case of some patients originate delusions of persecution directed, not against the object of affection, but against those who are supposed to have conspired to prevent the success of the patient’s desires. Under the influence of these delusions of persecution the patient may lose self-control and resort to violence against his supposed persecutors.

The subjects of this form of paranoia are in the majority of instances unmarried women well advanced in years who have led irreproachable lives, or men of a romantic disposition who have lived their mental lives more in the realm of chimeras than in the region of real facts. The delusions in this form of paranoia are never accompanied by hallucinations.

Closely allied, if not identical with amatory paranoia, is the form in which jealousy forms the basis of morbid suspicions
with or without definite delusions. The subject is usually poor in mental resources, but proud, vindictive and suspicious. It is eminently a condition which arises spontaneously in certain persons whose mental constitution is of the paranoiac type, i.e., persons who are naturally credulous, mystical and suspicious. The subjects are extraordinarily assiduous in watching the objects of their jealousy, whether husbands, wives or sweethearts. Their conduct in this respect is fertile in producing domestic dispease and unhappiness, and in the case of unmarried persons in creating complicated or delicate situations. It is not infrequently happens, just as in the case of the class of amatory paranoiacs, that delusions of persecution establish themselves, usually directed towards persons who are believed to have secured the affections of the object of jealousy. The disease then follows the ordinary course of the insanity of persecution but usually without hallucinations of the senses. The subjects are highly dangerous and violent. Under the influence of their delusions murder and even mutilation may be resorted to by the male, and poisoning or vitriol-throwing by the female subjects.

4. Litigious Paranoia (paranoia querulus).—The clinical form of litigious paranoia presents uniform characteristic features which are recognized in every civilized community. The basic emotion is vanity, but added to that is a strong element both of acquisitiveness and avarice. Moreover the subjects are, as regards character, persistent, opinionative and stubborn. When these qualities are superadded to a mind of the paranoiac type, which as has been pointed out, is more influenced by the passions or emotions than by ordinary rational considerations, it can readily be appreciated that the subjects are capable of creating difficulties and anxieties which sooner or later may lead to their forcible seclusion in the interests of social order.

It is important to observe that the same subjects may lay claim to or the wrongs they complain of may not necessarily be imaginary. But, whether imaginary or real, the statement of their case is always made to rest upon some foundation of fact, and is moreover presented, if not with ability, at any rate with forensic skill and plausibility. As the litigants are persons of one idea, and only capable of seeing one side of the case—their own—and as they are actuated by convictions which preclude feelings of delicacy or diffidence, they ultimately succeed in obtaining a hearing in a court of law under circumstances which would have discouraged any normal individual. Once in the law courts their doom is sealed. Neither the loss of the case nor the payment of heavy expenses have any effect in disheartening the litigant, who carries his suit from court to court until the methods of legal appeal are exhausted. The suit may be raised again and again on some side issue, or some different legal personality may be initiated. In spite of the alienation of the sympathy of his relations and the advice of his friends and lawyers the paranoiac continues his futile litigation in the firm belief that he is only defending himself from fraud or seeking to regain his just rights. After exhausting his means and perhaps those of his family and finding himself unable to continue to litigate to the same advantage as formerly, delusions of persecution begin to establish themselves. He accuses the judges of corruption, the lawyers of being in the pay of his enemies and imagines the existence of a conspiracy to prevent him from obtaining justice. One of two things usually happens at this stage. Though well versed in legal procedure he may one day lose self-control and resort to threats of violence. He is then probably arrested and may on examination be found insane and committed to an asylum. Another not uncommon result is that finding himself non-suited in a court of law he commits a technical assault upon, it may be, some high legal functionary, or on some person in a prominent social position, with the object of securing an opportunity of directing public attention to his grievances. The only result is, as in the former instance, his medical certification and incarceration.

Paranoia is generally a hopeless affliction from the point of view of recovery. From what has been stated regarding its genesis and slow development it is apparent that no form of ordinary medical treatment can be of the least avail in modifying its symptoms. The best that can be done in the interests of the patients is to place them in surroundings where they can be shielded from influences which aggravate their delusions and in other respects to make their unfortunate lot as pleasant and as easy to endure as possible.
PARAPET—PARASITIC DISEASES

1899; Magnan, Le Dëhre chronique (Paris, 1899); Stewart Paton, Psychiatry (Philadelphia, 1905); Percy Smith, "Paranoid," in Journ. of Mental Science (1904), p. 607. (J. MN.)

PARAPET (Ital. parapeto, Fr. parapet, from para, imperative of Ital. parare, to cover, defend, and petto, breast, Lat. pecus; the German word is Brustwacht), a dwarf wall along the eige of a roof, or round a lead flat, terrace wall, &c., to prevent persons from falling over, and as a protection to the defenders in case of a siege. Parapets are either plain, embattled, perforated or panelled. The last two are found in all styles except the Romanesque. Plain parapets are simply portions of the wall generally overhanging a little, with a coping at the top and corbel table below. Embattled parapets are sometimes pan léd, but oftener pierced for the discharge of arrows, &c. Perforated parapets are pierced in various devices—as circles, trefoils, quatrefoils and other designs—so that the light is seen through. Panelled parapets are those ornamented by a series of ovals, either oblong or square, and more or less enriched, but are not perforated. These are common in the Decorated and Perpendicular periods.

PARAPHERNALIA (Lat. paraphernalia, sc. bona, from Gr. παραφύρω; παρά, beside, and φύρω, dower), a term originally of Roman law, signifying all the property which a married woman who was sui juris held apart from her dower (dos). A husband could not deal with such except with his wife's consent. Modern usages of the word, which are kept up by the Roman, mainly follow the same principle, and the word preserves its old meaning. In English and Scottish law the term is confined to articles of jewelry, dress and other purely personal things, for the law relating to which see HUSBAND AND WIFE.

The word is also used in a general sense of accessories, external equipment, cumbersome or showy trappings.

PARAPHRASE (Gr. παραφράσας, from παραφράω, to relate something in different words, παρά, beside, and φράω, speak, tell), a rendering into other words of a passage in prose or verse, giving the sense in a fuller, simpler or clearer fashion, also a free translation or adaptation of a passage in a foreign language. The term is specifically used in the Scottish and other Presbyterian churches of metrical versions for singing of certain passages of the Bible.

PARASCENIUM (Gr. παρασκενίων), in a Greek theatre, the wall on either side of the stage, reaching from the back wall (σκηνή) beyond the orchestra (ορθηχορ)."}

PARASITE (From Gr. παρά, beside, σῶς food), literally "mess-mate," a term originally conveying no idea of reproach or contempt, as in later times. The early parasites may be divided into two classes, religious and civil. The former were assistants of the priests, their chief duty being to collect the corn dues which were contributed by the farmers of the temple lands or which came in from other sources (Athenaeus vi. 235; Pollix vi. 35). Considerable obscurity exists as to their other functions, but they seem to have been charged with providing food for the visitors to the temples, with the care of certain offerings, and with the arrangement of the sacrificial banquets. In Attica the parasites appear to have been confined to certain demes (Acharnæ, Diomeia), and were appointed by the demes to which the temples belonged. The "civil" parasites were a class of persons who received invitations to dine in the pryaneum and subsequently in the tholos) as distinguished from those who had the right to dine there eις αὑτήν. An entirely different meaning ("andler "sponger ") became attached to the word from the character introduced into the Middle and New Comedy, first by Alexis, and firmly established by Diphilus. The chief object of this class of parasites was a good dinner, for which they were ready to submit to almost any humiliation. Numerous examples occur in the comedies of Plautus; and Alciphron and Athenaeus (vi. 236 sqq.) give instances of the insults they had to put up with at the hands of both host and guests. Some of them played the part of professional jesters (like the later buffoons and court fools), and kept collections of witticisms ready for use at their patrons' table; others relied upon flattery, others again descended to the most degrading devices (Plutarch, De adulatore, 23; De educatione purorum, 17). The term parasite, from meaning a "hanger-on," has been transferred to any living creature which has an another one.

See Juvenal v. 170 with J. E. B. Mayor's note, and the exhaustive article by M. H. Meier in Ersch and Gruber's Allgemeine Encyclopädie.

PARASITIC DISEASES. It has long been recognized that various specific pathological conditions are due to the presence and action of parasites (see PARASITISM) in the human body, but in recent years the part played in the causation of the so-called infective diseases by various members of the Schizomyces—fission fungi—and by Protozoan and other animal parasites has been more widely and more thoroughly investigated (see BACTERIOLOGY). The knowledge gained has not only modified our conception of the pathology of these diseases, but has had a most important influence upon our methods of treatment of sufferers, both as individuals and as members of communities. For clinical and other details of the diseases mentioned in the following classification, see the separate articles on them; the present article is concerned mainly with important modern discoveries as regards aetiology and pathology. In certain cases indeed the aetiology is still obscure. Thus, according to Guarnieri, and Councilman & Calkins, there is associated with vaccinia and with small-pox a Protozoon parasite, Cytocytes variolae, Gaur. This parasite is described as present in the cytoplasm of the stratified epithelium of the skin and mucous membranes in cases of vaccinia, but in the nuclei of the cells in cases of variola or small-pox, whilst it is suggested that there may be a third phase of existence, not yet demonstrated, in which it occurs as minute spores or germs which are very readily carried in dust and by air currents from point to point. In certain other conditions, such as mumps, dengue, epidemic dropsy, oriental sore—with which the Leishman-Donovan bodies (Hedasoma tropicum, Wright) are supposed to be closely associated (see also Kala-azur below)—verruga, framboesa or yaws—with which is commonly associated a spirochaete (Castellani) and a special microcosocus (Pierz, Nichols)—and beri-beri, the disease may be the result of the action of specific microorganisms, though as yet it has not been possible to demonstrate any aetiological relationship between any microorganisms found and the special disease. Such diseases as haemoglobiniferous fever or black-water fever, which are also presumably parasitic diseases, are probably associated directly with malaria; this supposition is the more probable in that both of these are recognized as occurring specially in those patients who have been weakened by malaria.

The following classification is based partly upon the biological relations of the parasites and partly on the pathological phenomena of individual diseases—

A.—Diseases due to Vegetable Parasites.

I.—To Schizomyces, Bacteria or Fission Fungi.

1. Caused by the Pyogenic Micrococci.

2. Caused by Specific Bacilli.

(a) Acute Infective Fevers.

Cholera. Insective Meningitis.
Typhoid Fever. Influenza.
Malaria Fever. Yellow Fever and Weil's Disease.
Relapsing Fever. Diphtheria.
Plague. Tetanus.
Pneumonia. Tuberculosis.

(b) More Chronic Infective Diseases (tissue parasites).

Glanders. Leprosy.

II.—To Higher Vegetable Parasites.

Actinomycosis, Madura Foot, Aspergillosis and other Mycoses.

B.—Diseases due to Animal Parasites.

I.—To Protozoa.

Malaria. Kala-azur.
Amebic Dysentery. Tsetse-fly Disease.
Haemoglobiniferous Fever. Sleeping Sickness.
Syphilis.

II.—To other Animal Parasites.

Filariasis, &c.
Fig. 1.—Spirochaeta pallida of Schaudinn (Spirochæma pallidum), the organism found in the early sores of syphilis; stained by Giemsa’s stain. X 1000 diam.

2.—Preparation of the Glanders bacillus (B. mallei), from a 12-hours’ agar-agar culture. X 1000 diam.

3.—Negri bodies (red with blue points) in and around the nerve cells of the cornu ammonis of a dog suffering from rabies. X 800 diam.

4.—Staphylococcus pyogenes aureus from a 12-hours’ agar culture. X 1000 diam.

5.—Malaria. Life cycle, in the blood, of the Tertian malarial parasite commencing with the small amoebulae and passing through the spore-bearing stages. X 1000 diam.

6.—Section of gland from a guinea-pig inoculated with the Glanders bacillus (B. mallei). X 1000 diam.

7.—Leishman-Donovan bodies found in the scraping made from the cut surface of the spleen from a case of Kala-Azar. X 1000 diam.

8.— Branched hyphal threads of the Ray fungus (Actinomyces, clubbed through thickening of the sheath.) X 1000 diam.

9.—The Trypanosoma Gambiense, seen in a blood film taken from a case of sleeping sickness. X 1000 diam.
PARASITIC DISEASES

PARASITIC DISEASES

C.—Infected Diseases in which an organism has been found, but has not finally been connected with the disease.

Hydrophobia. Scarlet Fever.

D.—Infected Diseases not yet proved to be due to micro-organisms.

A.—Diseases due to Vegetable Parasites.

I.—To Schizomycetes, Bacteria or Fission Fungi.

Saprophytic and Septicaemia.—It is now recognized that although nitrate of silver, turpentine, castor oil, perchloride of mercury and certain other chemical substances are capable of producing suppuration, the most common causes of this condition are undoubtedly the so-called pus-producing bacteria. Of these perhaps the most important are the staphylococcus ( cocci arranged like bunches of grapes), streptococcus ( cocci arranged in chains), and pneumococcus, though certain other organisms not usually associated with pus-formation are undoubtedly capable of setting up this condition, e.g. Bacillus pyocyaneus, Bacillus coli communis, and the typhoid bacillus. These organisms (the products of which by chemical irritation, stimulate the lymphatics or by emigration) bring about the death and digestion of the tissues and fluids (which no longer "clot") with which they come in contact, pus (matter) being thus formed: this accumulates in the tissues, in the serous cavities, or even on mucous surfaces; septicaemia or blood-poisoning, secondary infection of tissues and organs at a distance from the original site of infection, or typhemia, with the formation of secondary abscesses, may thus be set up.

In septicaemia the pus-forming organisms grow at the seat of introduction, and produce special poisons or toxins, which, absorbed into the blood, give rise to symptoms of fever. From the point of introduction, however, the organisms may be swept away either by the lymph or by the blood, and carried to positions in which they set up further inflammatory or suppurrative changes. In the streptococcal inflammations spreading by the lymph channels appears to be specially prevalent. In the blood the organisms, if in small numbers, are usually destroyed by the plasma, which has a powerful bactericidal action; should they escape, however, they are carried without multiplication, or from one part of the body to another. In the blood, the general circulation, or of the liver, where, being stopped, they may give rise to a second focus of infection, especially if at the point of impaction the vitality of the tissues is in any way lowered. Unless the blood is very much impoverished, its bactericidal action is usually sufficiently powerful to bring about the destruction of anything but comparatively large masses of pyogenetic organisms. This bactericidal power, however, may be lost; in such case the pus-forming organisms may actually multiply, a general haemorrhagic infection resulting. Should micro-organisms be conveyed by the veins to the heart, and there be deposited on an injured valve, an infective endocarditis is the result; from such a deposit numerous organisms may be continuously poured into the circulation. Simple thrombi or clots may also become infected with micro-organisms. Fragment of these, washed away, may form septic plugs in the vessels and give rise to abscesses at the points where they become impacted. A distinction must be drawn between saprophyemia and septicaemia. In saprophyemia the toxic products of saprophytic organisms are absorbed from a gangrenous or necrotic mass, from an ulcerating surface, or from a large surface on which saprophytic organisms are living and feeding on dead tissues: for example, we may have such a condition in the clots that sometimes remain after childbirth on the inner surface of the wall of the womb. So long as no micro-organisms follow the toxins, the condition is purely saprophytic, but should any organisms make their way into and multiply in the blood, the condition becomes one of septicaemia. The term pyaemia is usually associated with the formation of fresh secondary foci of suppuration in distant parts of the body. If the primary abscess occurs in the lungs, the secondary or metastatic abscesses usually occur in the vessels of the general or systemic circulation, and less frequently in other vessels of the lung. When the primary abscess occurs in the systemic area, the secondary abscess occurs first in the lung, and less frequently in the systemic vessels; whilst if the primary abscess be in the portal area (the veins of the digestive tract), the secondary abscesses are usually distributed over the same area, the lungs and systemic vessels being more rarely affected.

Infective Endocarditis.—Acute malignant or ulcerative endocarditis occurs in certain forms of septicaemia or of pyaemia. It is brought about by the streptococcus pyogenes (see Plate II. fig. 2), the pneumococcus, or the Staphylococcus pyogenes aureus (see Plate I. fig. 4), or, more rarely, by the gonococcus, the typhoid bacillus or the tubercle bacillus, as they gain access to acute or chronic valvular lesions of the heart. The aortic and mitral valves are usually affected, the pulmonary and tricuspid valves much more rarely, though Washbourn states that the infective form occurs on the right side more frequently than does simple endocarditis. A rapid necrosis of the surface of the valve is early followed by a deposition of fibrin and leucocytes on the necrotic tissue; the bacteria, though not present in the blood, but in the fibrinous vegetations which break down very rapidly; ulcerative lesions are thus formed, and fragments of the septic clot (i.e. the fibrinous vegetations with their enclosed bacteria) are carried in the circulating blood to different parts of the body, and, becoming impacted in the smaller vessels, give rise to septic infarcts and abscesses. The ulceration of the valves, or in the first part of the aorta, may be so extensive that aneurysm, or even perforation, may ensue.

In certain cases of streptococcic endocarditis the use of anti-streptococcic serum appears to have been attended with good results. Sir A. Wright found that the introduction of vaccines prepared from the pus-producing organisms after first lowering the opsonic index almost invariably, after a very short interval, causes it to rise. He found, too, that the vaccine is specially efficacious when it is prepared from the organisms associated with the special form of suppuration to be treated. Whenever the opsonic index becomes higher under this treatment the suppurrative process gradually subsides: boils, acne, pustules, carbuncles all giving way to the vaccine treatment. The fibrinous or opsonic index may be regarded as an index of the intensity of the activities of the leucocytes that are found in such enormous numbers in the neighbourhood of suppurrative organisms and their products.

Erysipelas.—In 1853 Fehleisen demonstrated that in all cases of active erysipelatous inflammation a streptococcus or chain of micrococci (similar to those met with in certain forms of suppuration) may be found in the lymph spaces in the skin. The multiplying streptococci found in the lymph spaces form an active poison, which, acting on the blood-vessels, causes them to dilate; it also “attracts” leucocytes, and usually induces proliferation of the endothelial cells lining the lymphatics. These cells—perhaps by using up all available oxygen—interfere with the growth of the streptococcus and act as phagocytes, taking up or devouring the dead or weakened micro-organisms. Both mild and severe phlegmonous cases of erysipelas are the result of the action of this special coccus, alone, or in
PARASITIC DISEASES

combination with other organisms. It has been observed that cancerous and other malignant tumours appear to recede under an attack of erysipelas, and certain cases have been recorded by both Fehleisen and Coley in which complete cessation of growth and degeneration of the tumour have followed such an attack. As the streptococcus of erysipelas can be isolated and grown in pure culture in broth, it was thought by these observers that a subcutaneous injection of such a cultivation might be of value in the treatment of cancerous tumours. No difficulty was experienced in setting up erysipelas by inoculation, but in some cases the process was so acute that the remedy was more fatal than the disease. The virulence of the streptococcus of erysipelas, as pointed out by Fehleisen and Coley, is greatly excited when the coccus is grown alongside the Bacillus prodigiosus and certain other saprophytic organisms which flourish at the body-temperature. It is an easier matter to control the action of a non-multiplying poison, even though exceedingly active, than of one capable, under favourable conditions, of producing an indefinite amount of even a weaker poison. The erysipelas virus having been raised to as high a degree of activity as possible by cultivating it along with the Bacillus prodigiosus—the bacillus of "bleeding" bread—in broth, is killed by heat, and the resulting fluid, which contains a quantity of the toxic substances that set up the characteristic erysipelas changes, is utilized for the production of an inflammatory process—which can now be accurately controlled, and which is said to be very beneficial in the treatment of certain malignant tumours. The accurate determination of the aetiology of erysipelas has led to the adoption of a scientific method of treatment of the disease. The Streptococcus erysipelatis is found, not specially in the zone in which inflammation has become evident, but in the tissues outside this zone: in fact, the streptococci appear to be most numerous in the lymphatics of the tissues in which there is little change. Before the appearance of any redness there is a dilatation of the lymph spaces with fluid, and the tissues become slightly oedematous. As soon, however, as the distension of vessels and the emigration of leucocytes, with the accompanying swelling and redness, become marked, the streptococci disappear or are imperfectly stained—they are undergoing degenerative changes—the inflammatory "reaction" apparently being sufficient to bring about this result.

If it were possible to set up the same reaction outside the advancing streptococci might not a barrier be raised against their advance? This theory was tested on animals, and it was found that the application of iodine, oil of mustard, cantharidines and similar rubefacients would prevent the advance of certain micro-organisms. This treatment was applied to erysipelial patients with the most satisfactory result, the spread of the disease being prevented whenever the zone of inflammation was extended over a sufficiently wide area.

Genorrhoea.—A micro-organism, the gonococcus, is the cause of gonorrhoea. It is found in the pus of the urethra and in the conjunctive lying between the epithelial cells, where it is seen adhering to the lining of the urethra and in the fluid of joints affected with gonorrhoeal arthritis; also in the pleural effusion and in the vegetations of gonorrhoeal endocarditis. It is a small diplococcus, the elements of which are flattened or slightly concave disks apposed to one another; these, dividing transversely, sometimes form tetrads. They are found in large numbers, usually in the leucocytes, adherent to the epithelial cells or lying free. They stain readily with the basic aniline dyes, but lose this stain when treated by Gram's method. The gonococcus is best grown on human blood-serum mixed with agar (Wertheim), though it grows on ordinary solidified blood-serum or on blood-agar. Like the pneumococcus, it soon dies out, usually before the eighth or ninth day, unless reinoculations are made. It forms a semi-transparent disk-like growth, with somewhat irregular margins, or with small processes running out beyond the main colony. It acts by means of toxins, which have been found to set up irritative changes when injected, without the gonococci, into the anterior chamber of the eye of the rabbit.

2. Caused by Specific Bacilli.
(a) Acute Infective Fevers.

Cholera.—In 1854 Koch, in the report of the German Cholera Commission in Egypt and India, brought forward overwhelming evidence in proof of his contention that a special bacterium is the causal agent of cholera; subsequent observers in all countries in which cholera has been met with have confirmed Koch's observation. The organism described is the "comma" bacillus or vibrio, one of the spirilla, which usually occurs as a slightly curved rod 1 to 2 μ in length and 0-5 to 0-6μ in thickness. These comma-shaped rods occur singly or in pairs; they may be joined together to form circles, half-circles, or "S"-shaped curves (see Plate II. fig. 3).

In cultivations in specially prepared media they may be so grouped as to form long wavy or spiral threads, each of which may have a length of ten, twenty, or even thirty, of the short curved vibrio; in the stools of cholera patients, especially during the earlier stages of the disease, they are found in considerable numbers; they may also be found in the contents of the lower bowel and in the substance of the contents of the intestines of the traveller, and albuminous material is also found, especially in the crypts and in and around the epithelium lining the follicles. It is sometimes difficult, in the later stages of the disease, to obtain these organisms in sufficiently large numbers to be capable of distinguishing them with the microscope. It is, however, possible, by using the Dunbar-Schottelius method they can be detected even when present in small numbers. A quantity of faintly alkaline meat broth, with 2% of peptone and 1% common salt, is inoculated with some of the contents of the intestine, and is placed in an incubator at a temperature of 35°C. for about twelve hours, when, if any cholera bacilli are present, a delicate pellicle, consisting almost entirely of short "comma" bacilli, appears on the surface. If this growth be allowed to multiply, the media become acid in the lower. After a time the pellicle is gradually lost, the cholera organisms being overgrown, as it were, by the other organisms. In order to obtain a pure culture of the cholera bacillus, remove a small fragment of the young film, shake it up thoroughly in a little broth, and then make a smear-plate culture; around the growing colony liquefication takes place, and the colony gradually sinks to the bottom of the liquefying area, which now appears as a clear ring.

The organism grows very luxuriantly in milk, in which, however, it may be no very easily isolated, so long as there are a few small, or otherwise, not be recognized by a faint aromatic and sweetish smell, which can scarcely be distinguished from the aromatic smell of the milk itself, except by the most practised nose.

The cholera bacillus may remain alive in water for some time, but it appears to be less resistant than many of the putrefactive and saprophytic organisms. It grows better in a saline solution (brackish water) than in perfectly fresh water; it flourishes in serum and other albuminous fluids, especially when peptones are present. Its power of forming poisonous substances appears to vary directly with the amount and nature of the albumen present in the nutrient medium; and though it grows most readily in the presence of peptone, it appears to form the active poison in milk, though some low albumen and other crude albumen to which there is not too free access of oxygen. From the experiments carried out by Koch, Nicati and Rietzsch, and Macleod, there appears to be no doubt that the healthy stomach and intestine are not favourable breeding-grounds for the cholera bacillus. In the first place, it requires an alkaline medium for its full and active development, and the acid found in a healthy stomach seems to exert an exceedingly deleterious influence upon it. Secondly, it appears to be incapable of developing except when left at rest, so that the active peristaltic movement of the intestine interferes with its development. Moreover, it forms its poison most easily in the presence of crude albumen. It is interesting to note what an important bearing these facts have on the personal and general spread of cholera. Large quantities of the cholera bacillus may be injected into the stomach of a guinea-pig without any intoxicative or other symptoms of cholera making their appearance. Further, healthy individuals have swallowed, without any ill effect, pills
PARASITIC DISEASES

Containing the dejecta from cholera cases, although cases are recorded in which "artificial" infection of the human subject has undoubtedly taken place, whilst, as Metchnikoff demonstrated, very young rabbits, deriving milk from mothers whose mammary glands have been smeared with a culture of the cholera vibrio, soon succumbed, suffering from the classical symptoms of this disease.

If, however, previous to the injection of the cholera bacillus the acidity of the stomach be neutralized by an alkaline fluid, especially if at the same time the peristaltic action of the intestine be paralysed by an injection of morphia, a characteristic attack of cholera is developed, the animal is poisoned, and in the large intestine a considerable quantity of fluid faeces containing numerous cholera bacilli may be found. There appear to be slight differences in the cholera organisms found in connexion with different outbreaks, but the main characteristics are preserved throughout, and are sufficiently distinctive to mark out all these organisms as belonging to the cholera group. Amongst the known predisposing causes of cholera are the inauspicious use of purgative medicines, the use of unripe fruit, insufficient food and intemperance. These may be all looked upon as playing the part of the alkaline solution in altering the composition of the gastric juices, and especially as setting up alkaline fermentation in the stomach and small intestine; beyond this, however, the irritation set up may bring about an accumulation of inflammatory serous fluid, from the albumen of which, as we have seen, the cholera organism has the power of producing very active toxins.

The part played by want of personal cleanliness, overcrowding and unfavourable hygienic conditions may be readily understood if it be remembered that the cholera bacillus may grow outside the body. The number of cases in which epidemics of cholera have been traced to the use of drinking-water contaminated with the discharges from cholera patients is now considerable. The more organic matter present the greater is the virulence of the water so contaminated; and the addition of such water to milk has, in one instance at least, led to an outbreak. If cholera dejecta be sprinkled on moist soil or damp linen, and kept at blood-heat, the bacillus multiplies at an enormous rate in the twenty-four or thirty-six hours; but, as seen in the Dunbar-Schottelius method, at the end of three or four days it is gradually overcome by the other bacteria present, which, growing strongly and asserting themselves, cause it to die out.

The importance of this saprophytic growth in the propagation of the disease can scarcely be over-estimated. Water which contains an ordinary amount of organic and inorganic matter in solution does not allow of the multiplication of this organism, which may soon die out; but when organic matter is present in excess, as at the margin of stagnant pools and tanks, development occurs, especially on the floating solid particles. This bacillus grows at a temperature of 30° C. on meat, eggs, vegetables and moistened bread; also on cheese, coffee, chocolate and dilute sugar solutions. In some experiments carried out by Cartwright Hood and the writer in connexion with the passage of the cholera organism through filters it remained alive in the charcoal filtering medium for a period of at least forty-two days, and probably for a couple of months. It must be remembered that cholera bacilli are gradually overcome or overgrown by other organisms, as only on this supposition can the immunity enjoyed by certain regions, even after the water and soil have been contaminated, provided that no fresh supply is brought in, "to relight the torch," be explained. In most of the regions in which cholera remains endemic the wells are merely dug-out pits beneath the slightly raised houses, and are open for the reception of sewage and excreta at all times. These dejecta contain organic material which serves as a nutriment on which infective organisms, derived from the soil and ground-water, may flourish. Not only dejecta, but also the rinsings from soiled linen and utensils used by cholera patients should be removed as soon as possible, "without allowing them to come into contact with the surface of the soil, with wells," or with vegetables and the like. The discovery of Koch's comma bacillus has so altered our conceptions of the aetiology of this disease that we now study the conditions under which the bacillus may multiply and be disseminated, instead of concerning ourselves with the cholera itself as some definite entity. Telluric agencies become merely secondary factors, the dissemination of the disease by winds from country to country is no longer regarded as being possible, whilst the spread of cholera epidemics along the lines of human intercourse and travel is now recognized. The virulent bacillus requires the human organism to carry it from those localities in which it is endemic to those in which epidemics occur. The epidemiologist has come to look upon the study of the cholera organism and the conditions under which it exists as of more importance than mere local conditions, which are only important in so far as they contribute to the propagation and distribution of the cholera bacillus, and he knows that the only means of preventing its spread is the careful inspection of everything coming from cholera-stricken regions. He also recognizes that the herding together of people of depressed vitality, under unhygienic and often filthy conditions, in quarantine stations or ships, is one of the surest means of spreading an epidemic of the disease; that attention should be confined to the careful isolation of all patients, and to the disinfection of articles of clothing, feeding utensils, and the like; that the comma bacillus can only be driven out of rooms by means of light and fresh air; that thorough personal, culinary and household cleanliness is necessary; that all water except that known to be pure should be carefully boiled; and that all excess, both in eating and drinking, should be avoided. The object of the physician in such cases must be first to isolate as completely as possible all his cholera patients, and then to get rid of all predisposing causes in the patients themselves, causes which have already been indicated in connexion with the aetiology of the disease.

Attention has frequently been drawn to the fact that patients who have lived for some time in a cholera region, or who have already suffered from an attack of cholera, appear to enjoy a partial immunity against the disease. Halliche, working on the assumption that the symptoms of cholera are produced by a toxin formed by the cholera organism, came to the conclusion that, by introducing first a modified and then a more virulent poison directly into the tissues under the skin, and not into the alimentary canal, it would be possible to obtain a certain insusceptibility to the action of this poison. He found that for this purpose the cholera bacillus, as ordinarily obtained in pure culture from the intestinal canal, is too potent for the preliminary inoculation, but is not sufficiently active for the second, if any marked protection is to be obtained. By allowing the organism to grow in a well-aerated culture the virulence is gradually diminished, and this virulence, once abolished, does not return even when numerous successive cultures are made on agar or other nutrient media. On the other hand, by passing the cholera bacillus successively through the peritoneal cavities of a series of about thirty guinea-pigs, he obtains a virus of great activity which is soon lost on agar, but, if it is passed at all necessary, from time to time, again to pass the bacillus through guinea-pigs, three or four passages now being sufficient to reinforce the activity.

From these two cultures the vaccines are prepared as follows: The surface of a slant agar tube is smeared with the modified cholera organism. After this has been allowed to grow for twenty-four hours, a small quantity of sterile water is poured into the tube, and the surface-grown bacilli are carried out into an emulsion in the water; this is then poured off, and the process is repeated until the whole of the growth has been removed. The mixture is made up with water to a bulk of 8 c.c., so that if 1 c.c. is injected the patient receives 0.4 of surface-growth; it is found that this quantity, when injected subcutaneously into a guinea-pig, gives a distinct reaction, but does not cause necrosis of the tissues.

If the vaccine is to be kept for any length of time, the emulsion is made with 0.5% carboxic acid solution, prepared with carefully sterilized water, and the mixture is made up to 6 c.c. instead of 8 c.c., since the carboxic acid appears to interfere slightly with the activity of the virus. The stronger virus is prepared in exactly the same way. The preliminary injection, which is made in the left flank, is followed by a rise in temperature and by local reaction.
PARASITIC DISEASES

After three or four hours there is noticeable swelling and some pain; and after ten hours a rise in temperature, usually not very marked, occurs. These signs soon disappear, and at the end of three or four days the second injection is made, usually on the opposite side. This second injection may be repeated at any time after the first within a year or two. The distribution of the disease is great, as women so frequently act as laundresses, cooks, housemaids, nurses and the like. Frosh states that out of 6708 typhoid patients 310 excrated bacilli for more than 10 weeks after convalescence; 144 of these were no longer carriers by the end of the 9th week. In other cases the attacks of diarrhea have been prolonged from four to nine years. Dr Donald Greig, in 1908, reported a case in which the patient appears to have been a typhoid carrier for fifty-two years from the time of convalescence. Frosh pointed out that the bacillus is carried in the body although often present in the faeces in enormous numbers may disappear and again reappear from time to time and that a continuous series of examinations is necessary before a convalescent patient can be declared free from the microbe. Anyone of the bacilli in the faeces should be watched closely.

Kerry found that when a small quantity of the cholera vibrio is injected into the peritoneal cavity of a guinea-pig highly immunized against cholera by Haffkine's vaccine and, that after these vibrios rapidly become motionless and granular, then very much swollen and finally "dissolve." This is known as Pfeiffer's reaction. A similar reaction may be obtained when a quantity of a culture of a vibrio inoculated on to a guinea-pig immunized against the cholera vibrio, or from a patient convalescent from the disease, is injected into the peritoneal cavity of a guinea-pig not subjected to any preliminary treatment; and, going a step further, it was found that the distribution of the cholera vibrio is brought about when even the mixture of vibrio and serum is made in a test tube. On this series of experiments as a foundation, the theory of acquired immunity has been reared.

Evidence has been collected that spirilla, almost identical in appearance with the cholera bacillus, may be present in water and in healthy stools, and that it is in many cases almost impossible to diagnose between these and the cholera bacillus; but although it may be that they are not invalid Koch's main contention, that a special form of the comma bacillus, which gives a compound group of reactions, is the cause of this disease, especially when these reactions are met with in an organism that comes from the human intestine.

Typhoid Fever.—Our information concerning the etiology of typhoid fever was largely increased during the last twenty years of the 19th century. In 1882 Eberth and Klebs independently, and in 1885 Coats, described a bacillus which has since been found to be intimately associated with typhoid fever. This organism (Plate II. fig. 4) usually appears in the form of a short bacillus from 2 to 30 in length and 0.3 to 0.4 in breadth; it has slightly rounded ends and is stained at the poles; it may also occur as a somewhat longer rod more equally stained throughout. Surrounding the young organism are numerous long and well-formed flagella, which give it a very characteristic appearance from that standpoint. At present there is no evidence from the typhoid bacillus forms spores. These bacilli are found in the adenosid follicles or lymphatic tissues of the intestine, in the mesenteric glands, in the spleen, liver and kidneys, and may also be detected even in the smaller lymphoid masses in the lung and in the post-typhoid abscesses formed in the bones, kidneys, or other parts of the body; indeed, it is probable that they were first seen by von Recklinghausen in 1871 in such abscesses. They undoubtedly occur in the dejecta of patients suffering from typhoid fever, whilst in recent years it has been demonstrated that they may also be found in the urine. It is evident, therefore, that the urine, as well as the faeces, may be the vehicle by means of which the disease has been unwittingly spread in certain otherwise inexplicable outbreaks of typhoid fever, especially as the bacillus may be present in the urine when the acute stage of the disease has gone by, and when it has been assumed that the bacillus is absent. When the bacillus is convalescent, he is no longer a focus from which the infection may be spread. Easton and Knox found typhoid bacilli in the urine of 21% of a series of their typhoid patients.

In 1896 Kayser demonstrated what had previously been suspected, that the typhoid bacilli may persist for considerable periods in the bile duct and gall bladder, whence they pass into the intestinal tract and are discharged with the evacuations. Patients in whom this organism was found as "carrier bacilli." They become convalescent and except that now and again they suffer from attacks of diarrhea they appear to be perfectly healthy. It has been observed, however, especially during these attacks of diarrhea, that being a "typhoid bacillus" carrier, they remain alive sufficiently long to enable them to multiply and flourish when again brought into contact with moist food, milk, etc.

When inoculated on potato, careful examination will reveal that certain almost invisible moist patches are present; these are made up of rapidly multiplying typhoid bacilli. The typhoid bacillus grows in gelatin, especially on the surface,

PARASITIC DISEASES

775

fever, which in certain respects it resembles; the temperature curve, however, has a more undulant character, except in the malignant type, where the temperature remains high throughout the course of the attack. According to Hughes, this disease is widely distributed in the countries bordering upon the Mediterranean south of latitude 46° N., and along the Red Sea littoral. Analogous forms of fever giving a "specific" serum reaction with the micrococcus of this disease are also met with in parts of India, China, Africa and America.

The Micrococcus melitensis (1887), which is found most abundantly in the enlarged spleen of the patient suffering from Malta fever, is a very minute organism (0-33a in diameter), ovoid or comma-shaped, somewhat motile; or, when fixed, it may be seen, if a drop of the blood taken directly from the spleen be smeared over the surface of agar nutrient medium, minute transparent colourless colonies appear; in thirty-six hours these have a slight amber tinge, and in four or five days from their first appearance they become opaque. These colonies, which flourish at the temperature of the human blood, cease to grow at the room-temperature except in summer, and if kept moist, soon die at anything below 60° F., though they may be preserved for some time by the ordinary methods of growth and multiplication in broth there is opacity of the medium at the end of five or six days, this being followed by precipitation, so that a comparatively clear supernatant fluid remains. It grows best at 30° to 32° C.; it is highly pathogenic; it is very vigorous and may resist desiccation for several weeks.

This organism is distinctly pathogenic to monkeys, and its virulence may be so increased that other animals may be affected by it. Though unable to live in clean or virgin soil, it may lead a saprophytic existence in soil polluted with faecal matter. Hughes maintains that the "viruses" leaves the body of goats and of man along with the faeces and urine. The importance of this in ambulatory cases is very evident, especially when it is remembered that goats feeding on grass, &c., which has come in contact with such urine are readily infected. It seldom appears to be carried for any considerable distance. Infection is not conveyed by the sputum, sweat, breath or scraping of the skin of patients, and infected dust does not seem to play a very important part in producing the disease. Hughes divides the fever into three types. In the malignant form the onset is sudden, there are headache, vomiting pain over the whole body, and sometimes vomiting; the temperature rapidly rises,uria appears; the tongue is furred, and swollen, and the breath very offensive; the temperature may continue for some time at 105° to 106° F. The stools in the diarrhoea which is sometimes present may be most offensive.

At the end of a few days the lungs become congested and pneumatic, the pulse weak, hyperpyrexia appears, and death ensues. A second type, by far the most common, is the "undulant" type, in which there is remittent pyrexia, separated by periods in which the patient appears to be improving. These pyrexic curves, from one to seven in number, average about ten days each, the first being the longest,—eighteen to twenty-three days. In an intermittent type, in which the temperature-curve closely resembles the hectic pyrexial curve of phthisis or suppuration, the "undulant" character is also marked. A considerable number of toxic symptoms make their appearance—localized neuritis, synovitis, anæmia, emaciation, bronchial catarrh, weakness of the heart, neuralgia, profuse night-sweats and similar affections. Patients suffering from it, though usually healthy, are often, even after prolonged attacks of the disease, but the mortality among patients suffering from organic mischief of any kind may be comparatively high. The diagnosis from malaria, phthisis, rheumatic affections and pneumonia, in most cases, is made fairly easily, but the serum agglutinating reaction (first demonstrated by Wright in 1897) with cultures of the Micrococcus melitensis, corresponding to the typhoid reaction with the typhoid bacillus, is sometimes the only trustworthy feature by which a diagnosis may be made between this fever and the above-mentioned diseases. About 50% of the goats in Malta give a positive agglutinative reaction and about 10% excrete the bacillus which contains the micrococcus.

Sir David Bruce, in his investigations on the tsetse fly disease, pointed out that certain wild animals although apparently in good health might serve as reservoirs for, or stores of, the N'gana parasite. He was therefore quite prepared to find

somewhat like the bacillus coli communis, but with a less luxuriant growth. This organism, when taken from young broth cultures, is a small vessel, about 3-5 years old—during the period at which flagella are seen—and examined microscopically, exhibits very lively movements. When, as pointed out by Gruber and Durand, blood-serum, in certain dilutions, from a case of typhoid fever is added to such a culture, the broth, at first turbid, owing to the suspended and moving microorganisms, gradually becomes clear, and a deposit is formed which is found to be made up of masses or clumps of typhoid bacilli which have lost their motility. This reaction is so characteristic and definite, that when the mixture is kept under examination under the microscope, it is quite possible to follow the slowing-down movement and massing together of the organisms. It is found, moreover, that normal blooded serum has no such effect on the bacilli. This property of the blood-serum is acquired at such an early date of the disease—sometimes even at the end of the first week—and occurs with such regularity, that typhoid fever may now actually be diagnosed by the presence or absence of this "agglutinating" property in the blood-serum. It must, however, be understood that such infections from typhoid fever, and diluted with saline solution, to 1 in 10, to 1 in 50, or in still greater dilution, causes the bacilli to lose their motility and to become aggregated into clumps within an hour, it may be concluded that the patient is suffering from typhoid fever; if this agglutination be not obtained with a dilution of 1 in 10, in from 15 to 30 minutes, experience has shown that the patient is not suffering from this disease. Certain other diseases, such as cholera, give a similar specific serum reaction with their specific organisms. These sera have, in addition, a slight common action—a general agglutinating power—which, however, is not manifested except in concentrated solutions, the higher dilutions failing to give any clumping action at all, except with the specific bacillus associated with the disease from which the patient, from whom the serum is taken, is suffering.

Wright and Semple, working on Haffkine's lines, introduced a method of vaccine against typhoid, corresponding somewhat to that devised by Haffkine to protect against cholera. They first obtained a typhoid bacillus of fairly constant virulence and of such strength and power of multiplication that an agar culture of 24 hours growth would be inoculated into five times three, or four hours; and will kill four fairly large guinea-pigs, each weighing 350 to 450 grams. A similar culture emulsified in bouillon or saline solution and killed by heating for five minutes at 60° C. is a vaccine sufficient for protection. If, however, a similar culture heated for the same period may be used as the vaccine. In either case the vaccine is injected under the skin of the loin well above the crest of the ilium. This injection is usually followed by pyrexia, which begins after two or four hours, and swelling and tenderness in the position of the nearest lymphatic glands, marked malaise, headache, a general feeling of restlessness and discomfort and a rise of temperature. The blood of a patient so treated early causes agglutination of typhoid bacilli and acts on these bacilli much as does cholera serum in Pfeiffer's reaction. At the end of ten days a second and stronger dose is given. After each injection there is, according to Wright, a "negative phase" during which the results of the previous injection may be seen. There seems to be no doubt that if this be done a very marked, though not complete, protection is conferred. For a time the agglutinative and lytic powers of the serum continue to rise and the patient is protected from typhoid bacilli, but a new series of injections is required. It is recorded in favour of this method of treatment that of 4502 soldiers of the Indian army inoculated 0-98% contracted typhoid, while 25,851 soldiers of the same army who were not inoculated overcast 25% (2,541) contracted typhoid. Interestingly, of the 4502 inoculated all but 1705 had been inoculated, but of these only 2% contracted typhoid, whilst of 10,529 uninoculated men 14% were attacked. Wright, who has been indefatigable in carrying out and watching this method of treatment, has compiled a large number of statistics dealing with 40,000 individuals of these 8600 were inoculated, and 21% contracted typhoid, 12% of these succumbing to the disease. Of the 41,000 uninoculated men 51% contracted the disease, 21% of those attacked succumbing.

Medicinal or Malta Fever.—Until comparatively recently, Mediterranean fever was looked upon as a "contagious
PARASITIC DISEASES

that the Micrococcus melitensis might similarly be "stored" in an animal which might show but slight, if any, manifestations of Malta fever. Localizations as to the direction in which to look were given in the following fashion. There was a strike amongst the dairymen supplying the barracks in Malta and it became necessary to replace the goats' milk in the dietary of the troops by condensed milk. What followed? In the first half of the year 1906 there had been 144 cases (in 1905 there had been 750 cases), in the second half after the alteration of the milk supply, only 32 cases were recorded and in 1907, 7 cases during the whole year. In the navy during the same period there were, in 1905, 498 cases, in 1906, 248 cases and, from January to September 1907, not a single case.

The most common method of infection is by the ingestion of milk, but, in the goats which had handled milk may also give rise to infection through finding its way into cuts, bruises, &c. In the goat the disease is of an extremely mild character, the clinical symptoms, which are present for two or three days only, being easily overlooked. In some cases, especially in the Mediterranean Fever Commission, goats died from the various methods of inoculation or as the result of feeding with contaminated or infected material. The micrococcus is often found in the circulating blood from which it may be excreted along with the urine. In dairy cows, during the milking process, it may be brought in from the general circulation and of most of the viscera, persisting longest in the spleen, kidneys and lymphatic glands. In the later stages of the disease the micrococcus is found in the milk even after it has been boiled. It is likewise highly resistant, as the author has shown, for it was observed that the milk of the goat is so dangerous, as now and again it may contain an enormous number of the specific micrococcus varying "within wide limits from day to day," although bearing no relation to the severity of the infection. The temperature, and presence of the Micrococcus melitensis in the milk appears to be merely the result of a mechanical flushing of the mammary glands by means of which the cocci multiplying therein are removed. As pointed out by the Mediterranean Fever Commission the majority of Malta fever from its vantage ground in the milk may make its way to ordinary ice-creams and to native cheeses, in which it appears to retain its full virulence. Monkeys are especially susceptible to the micrococcus, for they react so rapidly that the milk contamination from an infected goat. In 1905 an interesting experiment was, unintentionally, carried out. An official of the United States Bureau of Animal Industry visiting Malta in the summer of that year purchased a herd of 61 milk-goats and four bilberry-goats. These were shipped via Antwerp to the United States. On arrival at Antwerp the goats were transferred to a quarantine station, where they remained for five days and were consigned by steamer to New York. On board the S.S. "Joshua Nicholson," which took the goats from Malta to Antwerp, were twenty-three officers and men; ten out of the twenty-three were afterwards traced. One was found to have been infected by M. melitensis at an unknown date, and eight had subsequently suffered from fever. Five of these had been contaminated by the micrococcus. It is interesting to note, however, that two men who boiled the milk before drinking it, and an officer and a cabin-boy who disliked the milk and did not drink it at all, came off scot free.

The above-mentioned cases might lead the question somewhat, as there was a possibility that the men attacked might have been in contact with infected patients in Malta. A far more conclusive case was the following. A woman at the quarantine station in New York, U.S.A., was so persistently struck with a cough and general coldness that the Milk Commission of New York suspected she may have been infected by M. melitensis, and therefore obtained milk from several goats, over a considerable period, suffered from a typical attack of Mediterranean fever about nine or ten weeks after the goats had been landed in America. In this case "contact" with other cases of exposure to infection by human patients could not be eliminated.

It may be held then that the M. melitensis leads a more or less passive existence in the body of the Maltese goat, only exercising its virulence when the goat is brought in contact with a human. There is some slight evidence that the Micrococcus melitensis may remain alive with its virulence unimpaired even when taken up by the mosquitoes Acrionymia and Stegomyia, and again in the common blood of milk, for the micrococcus has, for a short interval, been detected in the milk, and it can be recovered for a longer period and still in a fairly virulent condition from the excreta of these insects. In spite of this, transmission of the disease by these insects, though apparently possible, does not seem to be very frequent. The micrococcus is also found with a vaccine prepared from the Micrococcus melitensis appears to exert a protective influence for a period of about four months, after which time there is a marked diminution in the immunity conferred on the animal.

Relapsing Fever.—The specific cause of relapsing fever (famine fever) appears to be the Spirillum Obermeierii, an organism which occurs in the blood (during the febrile stages) of patients suffering from this disease. During the febrile stages are periods of intermission, during which the spirillum disappears from the blood and, apparently, retires to the spleen. This disease, in epidemic form, follows in the footsteps of famine and destitution, specially affecting young people between the ages of fifteen and twenty; it seldom attacks children under five years of age, but when it attacks patients over thirty it assumes a very virulent form. In monkeys inoculated with blood containing the Spirillum Obermeierii the first symptoms appear between the second and sixth days. In the human subject this incubation period may last as long as three weeks; then comes an attack of fever, which continues for about a week, and is followed by a similar period of apparent convalescence, on which ensues a pyrexial relapse, continuing about half as long as the first. The spirilla, the cause of this disease, are fine spirals with pointed ends, three or four times as long as the diameter of a red blood corpuscle. Although it has as yet been found impossible to cultivate these spirilla outside the body, human beings, and monkeys injected with blood containing the organism have contracted this disease; and in monkeys it has been found that during the period before the relapse the spirilla have made their way into the cells of the spleen. As yet little is known as to the mode of development of these organisms, and of their method of transmission from one patient to another, but it is thought that, as in the case of malaria and the taoe-fly disease, they may be carried by blood-sucking insects. Relapsing fever is distinguished from typhoid fever by its sudden onset, and by the distinct intermissions; and from influenza by the enlargement of the spleen and liver. The most satisfactory method of diagnosis is the examination of the blood for the presence of the spirillum during the febrile stage. The post-mortem appearances are those of a toxic (bacterial) poisoning. Curious infarction-like masses, in which are numerous spirilla, are found in the spleen; in the liver there is evidence of acute interstitial hepatitis, with cloudy swelling of the liver cells; and in the lungs, there is a brown, rounded abscess, that may be formed on the heart and voluntary muscles may also be met with.

Plague.—During recent years opportunities for the study of plague have unfortunately been only too numerous. In patients suffering from this disease, a micro-organism, capable of leading either a saprophytic life or a parasitic existence in the human body, and in some of the lower animals, was described independently by Kitasato and Lowson and by Yersin, 1894, in Hong-Kong. It is a short moderately thick oval bacillus, with rounded ends, which stain deeply, leaving a clear band in the centre (see Plate II., fig. 7). It is thus resembles the short diptheria bacillus and the influenza bacillus. Certain other forms are met with—long rods and large oval bacilli, pear-shaped or round, imperfectly stained pale involution forms—but the above is the most characteristic. It grows readily on most media at the temperature of the body, but, like the glands bacillus, soon loses its virulence in cultivations. It may be obtained in pure cultures from the lymph glands, and from the abscesses that are formed in the groin or other positions in which the glands become enlarged and softened. It may also be found in the spleen and in the blood, and, in the case of patients suffering from the pneumonic form of the disease, even in the lungs and in the sputum. It has also been found under the faeces and urine. (It is very important that these excreta from plague patients should always be most carefully disinfected.) This organism, when obtained in pure culture and inoculated into rats, mice, guinea-pigs or rabbits, produces exactly the same symptoms as does material taken fresh from the softened glands. The symptoms are local swelling, enlargement and softening of the lymphatic glands, and high fever.

The difficulty of explaining the spread of plague, at one time apparently almost insuperable, has at last been overcome, as it has been found that although the acute pneumonic plague is undoubtedly highly contagious, the spread of the bubonic and septiæmic forms could not be explained on the same hypothesis. As the pneumonic form is met with in only about 2.5% of the whole of the cases, transmission by direct contagion seems to be an utterly inadequate explanation. In the autumn of 1896, when the plague broke out in India, and those dealing
with the outbreak came to the conclusion that certain houses were centres of infection, it was noticed that those houses were most infective at night, and that they might actually be centres of infection although uninhabited; indeed the infection seemed to spread to houses between which and the infected house there appeared to be no intercommunication of any kind. This seemed to be inexplicable except on the assumption that the infective agent, the Bacillus pestis, was, in some way or other, carried by animals. It had already been noted that rats disappeared from plague-stricken houses, many dying before the appearance of the plague in the human population. Simond, noting these conditions, suggested that the plague bacillus might be transmitted by the flea from rat to rat and from rat to man. Although he was not able to demonstrate this connexion he indicated a line of research to other observers, who, as knowledge accumulated, were able to complete each link in the chain of infection. The plague bacillus having been found in the rat, the next step was to demonstrate its presence in the flea, and living plague germs were found in the stomachs of fleas inhabiting plague-infected houses. Several species seem to be able to transmit this germ, but in none of them does the plague bacillus appear to have developed in the intergenerational generations of the like—as in the case of the protozoon of malaria in its passage from to and the mosquito and the human subject—it simply passes unchanged through the alimentary canal of the flea, is excreted in the faeces, and is carried into the wound made by the epipharynx-mandibles of the flea.

At least three species of animals, two rats and the human subject, and three species of fleas are involved in this chain. The rat fleas are Pulex cheopis found in India, and Ceratophyllus fasciatus, the rat flea of northern Europe, and Pulex irritans, the common flea, all of which have the power of transmitting the disease. In India of course the Pulex cheopis, usually solely associated with rats, seems to play the most prominent part. The two rats involved are the Mus decumanus, or brown rat, which is found in the sewers and develops the plague first, and the Mus rutilus, the common black house-rat. From the sewer-rat the house-rat is infected, and from the house-rat man. Under ordinary conditions rat fleas do not attack the human subject, but, as the rats are attacked by plague and die, the infected fleas, starve out as it were, leave them and transfer their attentions to other animals and the human subject, infecting many of those they bite. Colonel Bannerman maintains that this infection takes place in the majority of cases, by this chain of transmission, and that there is no evidence that the excreta of these rats infect food or contaminate the soil. Colonel Lamb, summarizing the experimental evidence on this question, writes:

"1. Close contact of plague-infected animals with healthy animals, if fleas are excluded, does not give rise to an epizootic among the latter. As the godowns (experimental huts) were never cleaned out, close contact includes contact with faeces and urine of infected animals, and contact with and eating of food contaminated with faeces and urine of infected animals as well as with pus from open plague ulcers; (2) close contact of young, even when suckled by plague-infected mothers, did not give the disease to the former (3) if plague is present, then the epizootic, once started, spreads from animal to animal, the rate of progress being in direct proportion to the number of fleas present; (4) an epizootic of plague may start without direct contact of healthy animal and infected animal and infected fleas; (5) transmission of the infection from rat to rat; (6) infection can take place without any contact with contaminated soil; (7) aerial infection is excluded."

The experiments lead to the conclusion that fleas and fleas alone, are the transmitting agents of infection. Bannerman gives in concise form similar evidence in relation to naturally infected native houses. Infection is carried from place to place by fleas, usually on the body or in the clothing of the human being. Such fleas, fed on infected blood, may remain alive for three weeks, and of this period, we are told, may remain infective for fifteen days. At the first opportunity these fleas forsake the human host and return to their natural host the rat. In most of the epidemics there is a definite sequence of events. First the brown rats are attacked, then the black rats, then the human subject, and Colonel Lamb suggests that after the rat disappears the flea starves from about three days and then the flea is probably killed. There comes the incubation period of plague, three days. Following this is the period of average duration of the disease, five or six days. This time-table, he says, corresponds to the period—when the epidemics are at their height—that intervenes between the maximum death-rate in rats and the maximum death-rate in man, about ten to fourteen days. This history of the connexion between the flea, the rat, and the human subject reads almost like a fairy tale, but it is now one of the well-authenticated and sober facts of modern medicine.

In India, where the notions of cleanliness are somewhat different from those recognized in Great Britain, most of the conditions favourable to the spread of the plague bacillus are of the most perfect character. This organism may pass into the soil with faeces; it may there remain for some time, and then be taken into the body of one of the lower animals, or of man, and give rise to a fresh outbreak. Kitasato and Yersin were both able to prove that soil and dust from infected houses contain bacilli that are capable of infecting an attack of plague in the lower animals, and that fleas fed on diseased districts or other bacillus-containing material, die, and in turn contain bacilli which are capable of setting up infection. Hankin claims that ants may carry the plague to and from rats, and so to the human being. It has already been mentioned that the organism rapidly loses its virulence when cultivated outside the body; on the other hand, on being passed through a series of animals its virulence gradually increases. Thus may be explained the fact that in most outbreaks of plague there is an early period during which the death-rate is very low; after a time the percentage mortality is enormously increased, the virulence of the disease being very great and its course rapid. There seem to be notable differences in the degree of susceptibility of different races and different individuals, and those who have passed safely through an attack appear to have acquired a marked degree of immunity.

Two methods of treatment, both of which seem to have been adopted with a certain degree of success, are now being tried. Haffkine, who was the first to produce a vaccine for the treatment of cholera, prepared a vaccine of a somewhat similar type for the treatment of plague. For this the Bacillus pestis is cultivated in broth; to this culture broth (Indian butter) is added; these form centres around which the organisms may develop. As the organisms multiply they grow down into the broth, but gradually becoming fewer in number as the floating organisms are engulfed by the surface mass, the latter come to resemble stalactites. These are broken off, from time to time, by shaking, others immediately beginning to form in their place. This may go on for six weeks. The flask with its contents is then well shaken and heated in a water bath to 70° C., from one to three hours. On testing by culture the fluid should now be sterile, i.e. no bacilli should remain alive, and the fluid, ready for use, may be injected into the subcutaneous tissues of the arm in a dose of from 3 cc. for a man and 2 to 2.5 cc. for a woman, children receiving relatively small amounts. A rise of temperature followed by malaise and headache, which pass off in about 24 hours, is soon noted, and some local swelling and redness appear at the site of injection. The Indian Plague Commission were satisfied that the use of this fluid was found to be of great utility. As it is now, that although it does not confer a complete immunity against the disease, the case mortality is lowered. They are of opinion also that protection is not conferred at once, but lieut-Colonel Bannerman states that the disease of both human beings and experimental animals may be produced when this vaccine is used, and that epidemic plagues may be produced in experimental animals, and that epidemic plagues may be produced in experimental animals.

In the official report (Annual Report of the Sanitary Commissioner with the Government of India) for 1904 occurs the following: That its value is great is certain, not only does it largely reduce the danger of plague being contracted, but, if it fails to prevent the attack, the probability of a fatal event is reduced by one-half.

This method of treatment, however, is of no avail in the case of patients already attacked, for each case Yersin's serum treatment must be applied in. Various other vaccines have been described, but all consist of some form of killed or attenuated bacilli, and the results attained do not vary very greatly. Yersin, who first demonstrated the plague bacillus also devised the method of raising an aqueous "antiserum." A horse was inoculated repeatedly, at intervals, and with gradually increasing doses of living plague bacilli. It was afterwards found that cultures sterilized by heat served equally well for this inoculation of the horse and of course were many more
PARASITIC DISEASES

easily worked with. This process of preparation may have to be continued for from six months to a year. The horse is then bled and from the clot the serum is separated, care being taken to determine by injection of the blood into mice that no living bacilli have by accident made their way into, and remained in, the horse's blood. Sera from such a horse as will kill a dressing of a half will protect the mouse against a dose of living bacilli fatal to a control mouse in from 48 to 60 hours. When this serum is injected in sufficiently large doses subcutaneously in mild cases, and subcutaneously or intraperitoneally (Isherwood, 1887) in more severe cases in doses of 150 to 300 cc., the results seem to be excellent, especially when the serum is injected into the tissues around the bubo or swellings formed in this disease. Calmette and Sahlinbeni under such treatments (1898) in the horse they had a mortality of under 15%, whilst amongst 72 patients not so treated the death-rate was over 65%. This serum kills the bacilli and at the same time neutralizes the toxin formed during their growth. The lethal amount of this serum was 20 cc. in more severe cases, and 10 cc. in mild cases, when large doses are given, and when the serum injected subcutaneously is thrown into the area in which the lymph flows towards the bubo. As in the case of the diphtheria antitoxic serum joint pains and rashes may follow its exhibition, but no other ill effects have been noted.

Pneumonia.—The case in favour of acute lobar pneumonia being an infective disease was a very strong one, even before it was possible to show that a special organism bore any aetiological relation to it. In 1880, Friedländer claimed that he had isolated such an organism, but the pneumo-bacillus then described appears to be inactive as compared with the pneumo-coccus isolated by Fraenkel and Talamon. This bacillus was described by them as an encapsulated diplo-coccus. Grown on serum or agar over which sterile blood has been smeared, it occurs as minute, glistening, rather prominent points, almost like a fine spray of water or dew. When the organism is cultivated in broth the capsule disappears, and chains of diplococci are seen. It resembles the influenza bacillus in a most remarkable manner. It may be found, in almost every case of pneumonia, in the "rusty" or " prune-juice" spumt. Injected into rabbits, it produces death with very great rapidity; and by passing the organism through these animals its virulence may be markedly increased. Like the influenza bacillus and even the diphtheria bacillus, this organism may be present in the mouth and lungs of perfectly healthy individuals, and it is only when the vitality of the system is lowered by cold or other depressing influences that pneumonia is induced; two factors, the presence of the bacillus and the lowered vitality, being both necessary for the production of this disease in the human subject. It is quite possible, however, that, as in the case of cholera, a slight inflammatory exudation may supply a nutrient medium in which the bacillus rapidly acquires increased virulence, and so becomes a much more active agent of infection.

It is claimed by the brothers Klemperer, by Washbourn and by others, that they have been able to produce an anti-pneumococcic serum, by means of which they are able to treat successfully severe cases of pneumonia. The cattarhal pneumonia so frequently met with during the course of whooping-cough, measles and other specific infective fevers, is also in all probability due to the action of some organism of which the influenza bacillus and the Diplococcus pneumoniae are types.

Infective meningitis is, in most of the recent works on medicine, divided into four forms: (1) the acute epidemic cerebro-spinal form; (2) a posterior basic form, which, however, is closely allied to the first; (3) suppurative meningitis, usually associated with pneumonia, erysipelas, and pyaemia; and (4) tubercular meningitis, due to the specific tubercule bacillus.

1. The first form, acute infective or epidemic cerebro-spinal meningitis, is usually associated with Weichselbaum's Diplococcus intracellularis meningitidis (two closely apposed disks), which is found in the exudate, especially in the leucocytes, of the meninges of the brain and cord. It grows, as transparent colonies, on blood-agar at the temperature of the body, but dies out very rapidly unless reinoculated, and has little pathogenic effect on any of the lower animals, though under certain conditions it has been found to produce meningitis when injected under the dura mater.

More or less successful attempts have been made to treat acute cerebro-spinal meningitis by means of antisera obtained from different sources. Flexner uses the serum of horses that have been highly immunized against numerous strains of the meningococcus, the process of immunization extending over four or five months. Meister, Lucius and Eršna supply Rupell's anti-bacterial serum derived from animals immunized against several strains of the meningococcus. The chlorinated or dried sera may be looked upon as polyvalent sera. Ivy Mackenzie and Martin, pointing out that the cerebro-spinal fluid, even of patients who have recovered from this form of meningitis, contains no anti-globulin, have made use of the serum of animals "boiled" in the spinal canal. In all cases the action seems to be much the same. These sera contain immune body and complement, and are distinctively bactericidal, acting on the meningococcus and rendering it harmless. The fluid, when heated, is said to resemble the treatment of lockjaw, where the antitetanus serum is brought as directly as possible into contact with the nerve centres.

The dose of these sera ranges from 15 to 40 cc. according to the severity of the disease. Although the general mortality of the disease is from 50 to 80%, it is stated that where Flexner's serum is used the mortality falls to 33%. The result corresponds somewhat closely to those obtained with antitoxin serum in diphtheria.

In patients injected on the first day of the disease the mortality was 14.4%, or 13.7% in the seventh day, but in the seventh day 36%. From this it is evident that although the serum has a distinct effect in bringing about the phagocytes of the meningococcus and the neutralization of the toxins produced, it does not make the disease an acute one. Mackenzie and Martin treated 20 cases with the blood taken from patients suffering, or convalescent, from meningitis. Of 14 acute cases treated 14 received serum from patients who had already recovered from the disease, 8 of the patients recovered, 2 died, and 2 cases which received their own serum both recovered. In the presence of these anti-cerebro-spinal-ferver sera the meningoccal become diminished in number and do not stain so readily, whilst, as is the case with antitoxin, the meningococcus is also diminished in number. The serum should be given until the temperature becomes normal. Mackenzie and Martin assert that even normal human blood contains substances which are bactericidal to the meningococcus and that this effect is due to the presence of an antitoxin and activity in the blood serum of patients suffering from an acute or chronic meningococcic infection, and the serum of a patient recently recovered from an infection shows the evidence of the presence of these substances in a still greater degree. They were also able to prove that the action of the antitoxin depends on an immune body which requires the presence of a complement to complete the process. The cerebro-spinal fluid differs from the serum in that it does not contain substances which kill the meningococcus, and is not capable of raising a complementary effect present in the blood, found in this cerebro-spinal fluid. Hence the efficacy of the blood when it is called upon to replace the fluid in the cerebro-spinal canal.

2. Posterior basic meningitis, according to Dr. Still, is "is frequently seen during the first six months of life, a period at which there is a decided spasm of the spinal meningitis is quite uncommon."

The organism found in this disease resembles the Diplococcus intracellularis meningitidis very closely, but differs from it in that it remains alive without recultivation for a considerably longer period. It is less pathogenetic than that organism, of which possibly it is simply a more highly saprophytic form. This is a somewhat important point, as it would account for the great resemblance that exists between the sporadic and the epidemic forms of meningitis.

3. In suppurative meningitis these two organisms may still be found in a certain proportion of the cases, but their place may be taken by the pneumococcus or Diplococcus pneumoniae or Fraenkel's pneumococc—Diplococcus lanceolatus—which appears to grow in two forms. In the first it is an encapsulated organism, consisting of small oval cocci arranged in pairs or in short chains; the capsule is unstained. When the pneumococcus grows in chains—the second form—as when cultivated outside the body, on blood-serum or on agar over the surface of which a small quantity of sterile blood has been smeared, it produces very minute translucent colonies. Like Weichselbaum's bacillus, it is solubilized in a matter of four days, otherwise it soon dies out. Unlike the other forms previously described, it may, when passed through animals, become extremely virulent, very small quantities being sufficient to kill a rabbit. Although the pneumococcus is found in the majority of these cases, especially in children, suppurative
meningitis may also accompany or follow the various diseases that are set up by the Streptococcus pyogenes and Streptococcus erysipelas; whilst along with it staphylococci and the Bacillus coli communis have sometimes been found. In other cases, again, there is a mixed infection of the pneumococcus and the Streptococcus pyogenes, especially in cases of disease of the middle ear. As might be expected in meningitis occurring in connexion with the specific infective diseases, e.g. influenza and typhoid fever, the presence of the specific bacilli of these diseases may usually be demonstrated in the meningeal pus or fluid.

4. The fourth form, tubercular meningitis (acute hydrocephalus), is met with most frequently in young children. It is now generally accepted that this condition is the result of the introduction of the tubercle bacillus into the blood-vessels and lymph spaces of the meninges at the base of the brain, and along the fissures of Sylvius.

Influenza.—From 1889 up to the present time, influenza has every year with unflagging regularity broken out in epidemic form in some part of the United Kingdom, and often has swept over the whole country. The fact that the period of incubation is short, and that the infective particles are extremely active at the very early stage of the disease, renders it one of the most rapidly-spreading maladies with which we have to deal. The infective agent, first observed by Pfeiffer and Canon, is a minute bacillus or diplococcus less that 1μ in length and 0.5μ in thickness; it is found in little groups or in pairs. Each diplococcus is stained at the poles, a clear band remaining in the middle; in this respect it resembles the plague bacillus. It is found in the blood—though here it seems to be comparatively inactive—and in enormous numbers in the bronchial mucus. It is not easily stained in a solution of carbol-fuchsine, but in some cases such numbers are present that a cover-glass preparation may show practically no other organisms. Agar, smeared with blood, and inoculated, gives an almost pure cultivation of very minute transparent colonies, similar to those of the Diplococcus pneumoniae, but as a rule somewhat smaller. This organism, found only in cases of influenza, appears to have the power of forming toxins which continue to act for some time after recovery seems to have taken place; it appears to exert such a general devitalizing effect on the tissues that micro-organisms which ordinarily are held in check are allowed to run riot, with the result that catarrh, pneumonia and similar conditions are developed, especially when cold and other lowering conditions co-operate with the poison. This toxin produces special results in those organs which, through over-use, impaired nutrition or disease, are already only just able to carry on their work. Hence in cases of influenza the cause of death is usually associated with the failure of some organ that had already been working up to its full capacity, and in which the margin of reserve power had been reduced to a minimum. It is for this reason that rest, nutrition, warmth and tonics are such important and successful factors in the treatment of this condition.

Yellow Fever, endemic in the West Indies and the north-eastern coast of South America, may become epidemic wherever the temperature and humidity are high, especially along the seaports in the tropical Atlantic coast of North America. It appears to be one of the specific infective fevers in which the liver, kidney, and gastro-intestinal systems, and especially their blood-vessels, are affected. In 1897 Sanarelli reported, in the Annales de l'Institut Pasteur, that he had found a bacillus in the blood-vessels of the liver and kidneys, and in the cells of the peritoneal fluid, but never in the alimentary tract, of yellow fever patients. These, he maintained, were perfectly distinct from the putrefactive microbes occurring in the tissues in the later stages, their colonies not growing like those of the bacillus coli communis. They grow readily on all the ordinary artificial nutrient media, as short rods with rounded ends, usually about 2 to 4μ in length and about half as broad as they are long. They are stained by Gram's method and readily by most of the aniline dyes, are ciliate, and do not liquefy gelatine. They flourish specially well alongside mounds, in the dark, in badly-ventilated, warm, moist places, and remain alive for some time in sea-water; these facts, as Sanarelli points out, may afford an explanation of the special persistence of yellow fever in old, badly-ventilated ships, and in dark, dirty and insanitary sea-coast towns. Once the organism, whatever it may be, finds its way into the system, it soon makes its presence felt, and toxic symptoms are developed. The temperature rises; the pulse, at first rapid, gradually slows down; and after some time persistent vomiting of bile comes on. At the end of three or four days the temperature and pulse fall, and there is a period during which the patient appears comparatively well; this is followed in a few hours by icterus and scanty secretion of urine. There may be actual anaemia, or the small quantity of urine passed may be loaded with casts and albumen; delirium, convulsions and haemorrhages from all the mucous surfaces may now occur, or secondary infections of various kinds, boils, abscesses, suppurations and septicaemia, may result. These often prove fatal when the patient appears to be almost convalescent from the original disease. As regards prognosis, it has been found that the lower the initial temperature the milder will the case be (Macpherson). An initial temperature of 106°F. is an exceedingly unfavourable sign. The following passage, from Boyce (his book on the isolation and cultivation of micro-organisms, published in 1891) is quoted by Boyce: "But rubbish! the small amount of sulphuretted hydrogen or marsh gas which might arise from a marsh could not possibly hurt a fly, much less a man. It is not that, it is a mosquito called in Cumana the 'Zancudo bobo,' the striped or domestic mosquito." Beauprethuy, recently as he wrote, then stood almost alone in this opinion. Now we know that yellow fever, in common with other specific diseases, is caused by the action of an organized virus. The search for a vegetable parasite, bacillus or micrococcus, as above indicated, has been very close and strenuous, but it may now be held that up to the present no bacillus or micrococcus, well authenticated as capable of causing yellow fever, has been discovered. Latterly a search has been made for protozoal organisms, organisms similar to those present in the blood of malignant patients and like conditions, or for spirochaetes similar to those associated with relapsing fever, and Boyce draws attention to the fact that a spirochaete has recently been identified in the tissues taken from cases of yellow fever. It has however been demonstrated that the virus, whatever it may be, is carried by a species of mosquito; this seems to favour the protozoan hypothesis, especially as it is found that the Stegomyia fasciata, Fab. (or S. calopus, Meig.), after taking the blood from an infected patient is not infective immediately but only becomes capable of infecting by its bite at the end of twelve days. It would appear therefore that residence in this mosquito is necessary for the material to become fully infective. During this period some special metamorphosis may occur, and metamorphosis essential to the development of the parasite, or, on the other hand, the time may be required for it to make its way to some position from which it may emerge from the mosquito when that insect occurs.
PARASITIC DISEASES

"strikes." In the interval between the bite of an infected Stegomyia and the appearance of the disease (5 or 6 days) the blood of the patient contains the virus which, when taken into the mosquito, may develop into the infective material; moreover, this virus persists alive and active for three days after the disease is fully developed, but at the end of this time it disappears, so far, at any rate, as its infective power is concerned, from the blood, secretions and tissues of the patient. Further, there is no evidence that the infective virus is ever transmitted directly from the patient in secretions or in fact in anything but blood or blood-serum. The infective material, then, is present in the human subject for about eight days, during which the blood and even the blood-serum may serve as a vehicle for the infective agent. If during this period the patient is bitten by the Stegomyia the mosquito cannot distribute the infection for twelve days, but after this the power of transmitting reinfection persists for weeks and even months during cold weather when the insect is torpid. As soon, however, as the warm weather comes round and the mosquito becomes active and again begins to bite there is evidence that it still maintains its power of transmitting infection; indeed Boyce states that mosquitoes infected in one year are capable of transmitting infection and starting a fresh epidemic in the following one. In the warm season, however, it is probable that a mosquito by a single bite is capable of setting up an attack of the disease, as we see important in this question.

The Stegomyia, known as the domestic or house mosquito, is spoken of as the "Tiger" mosquito, "Scots' Grey," or "Black and White Mosquito," from the fact that there is a lyre-shaped pattern in white on the back of the thorax, transverse white bands on the abdomen, and white spots on the sides of the thorax; while the legs have white bands with the last hind tarsal joint also white" (Boyce). It is also spoken of as the "cistern mosquito," as it breeds in the cisterns, barrels, water butts, &c., containing the only water-supply of many houses. It may pass through its various stages of development in any small vessels, but the larvae are not usually found in natural collections of water, such as gutters, pools or wells, if the ovipositing insect can gain access to cleaner and purer water.

The egg of the Stegomyia deposited on the water develops in from 10 to 24 hours into the larval form, the so-called "wiggle-worm," the next stage for from 1 to 8 days, then becomes a pupa, and within 48 hours becomes a fully developed mosquito. The larvae can only develop if they are left in water, though a very small amount of water will serve to keep them alive. The eggs on the other hand are very resistant, and even when removed from water may continue viable for as long a period as three months. The Stegomyia affects clean water-butts and cisterns by preference. Consequently its presence is not confined to unhygienic districts; they may, however, "seek refuge for breeding purposes in the shallow street drains and wells in the town." The Stegomyia does not announce its advent and attack by a "ping" such as that made by the Anopheles, it works perfectly noiselessly and almost ceaselessly (from 3 p.m. to early morning) so that any human beings in its neighbourhood are not safe from its attacks either afternoon or night.

The most important prophylactic measures against the Stegomyia are ample mosquito nets "with a gauge of eighteen meshes to the inch" (Boyce), so arranged that the person sleeping under them is not even touched by the wings of the mosquitoes near the net; these nets should be used not only at night but at the afternoon siesta. Then the living room should be screened against the entrance of these pests, thorough ventilation should be secured; and all pools and stagnant waters, especially in the neighbourhood of houses, should be drained, water-butts and cisterns should be screened and all stagnant waters oiled with kerosene or petroleum, where drainage is impossible. What has been done through the carrying out of these and similar measures may be gathered from the record of the Panama Canal. In 1884 the French Panama Canal Company, employing from 15,000 to 18,000 men, lost by death 60 per 1000 annually (in 1885 over 70 per 1000). In 1904, when the Americans had taken over the work of construction, Col. W. C. Douglas undertook to clear the country of the Stegomyia, and within two or three years yellow fever had been eradicated. The death-rate from malaria was also greatly diminished, and by the end of 1907 the death-rate per annum amongst 45,000 workers was only 15 per 1000, a lower death-rate than is met with in many large English towns. Similar examples might be cited from other places, but the above is sufficiently striking to carry conviction that the methods employed in carrying on the warfare against tropical diseases have been attended with unexampled success. These diseases, at one time so greatly feared, are now so much under control that some one has said "we long we shall be sending our patients to the tropics in search of a health resort."

Well's disease, a disease which may be considered along with acute yellow atrophy and yellow fever, is one in which there is an acute febrile condition, associated with jaundice, inflammation of the kidney and enlargement of the spleen. It appears to be a toxie condition of a less acute character, however, than the other two, in which the functions and structure of the liver and kidney are specially interfered with. There is an affection of the gastro-intestinal system, and the nervous system is also in some cases profoundly involved. Haemorrhage into the mucous and serous membranes is a marked feature. The liver cells and kidney epithelium are affected to a high degree, and in the urine there is a cloudy swelling, probably also toxic in origin. Organisms of the Proteus group, which appear to have the power, in certain circumstances, of forming toxic substances in larger quantities than can be readily destroyed by the liver, and which then make their appearance in the kidney and spleen, are supposed to be the cause of this condition.

Diphtheria.—In regard to no disease has medical opinion undergone greater modification than it has in respect of diphtheria. Accurately applied, bacteriology has here gained one of its greatest triumphs. Not only have the aetiology and diagnosis of this disease been made clear, but knowledge acquired in connexion with the production of the disease has been applied to a most successful method of treatment. In 1875 Klebs described a small bacillus with rounded ends, and with, here and there, small clear unstained spaces in its substance. He, however, also described streptococci as present in certain cases of diphtheria, and concluded that there must be two kinds of diphtheria, one associated with each of these organisms. In 1883 he again took up the question; and in the following year another bacillus was described, which is known as the Klebs-Loeffler bacillus, which was afterwards proved by Roux and Yersin and many other observers to be the cause causans of diphtheria. This bacillus is a slightly-curved rod with rounded, pointed, or club-shaped end or ends (see Plate II. fig. 9). It is usually from 1 to 5 μ in length and from 0.3 to 0.5 μ in breadth; rarely it may be considerably larger in both dimensions. It is non-motile, and may exhibit great variety of form, according to the age of the culture and the nature of the medium upon which it is growing. It is stained by Gram's method if the decolorizing process be not too prolonged, and also by Loeffler's methylene-blue method. Except in the very young forms, it is readily recognizable by a series of transverse alternate stained and unstained bands. The bacillus may be wedge-shaped, spindle-shaped, comma-shaped or ovoid. In the shorter forms the polar staining is usually well marked; in the longer bacillus, the transverse striation. Very characteristic club-shaped forms or branching filaments are met with in old cultures, or where there is a superabundance of nutrition. In the former case, the middle of the club the banded appearance is specially well marked. In some specific bacilli are found in large numbers on the surface of the diphtheritic membrane (Plate II. fig. 10), and may easily be detached for bacteriological examination. In certain cases they may be found by direct microscopic examination, especially when they are stained by Gram's method, but it is far more easy to demonstrate their presence by the culture method. On Loeffler's special medium the bacillus flourishes so well at body-temperature—about 37° C.—that, like the cholera bacillus, they outgrow the other organisms present, and may be obtained in comparatively
pure culture. Distinct colonies may often be found as early as the eighth or twelfth hour of incubation; in from eighteen to twenty-four hours they appear as rounded, elevated, moderately translucent spots to the naked eye, with a yellow tinge, the surface moist and the margins slightly irregular or scalloped. They are thicker and somewhat more opaque in the centre. When the colonies are few and widely separated, each may grow to a considerable size, 4 to 5 mm.; but when more numerous and closer together, they remain small and almost invariably discrete, with distinct intervals between them. In older growths the central opacity becomes more marked and the creation more distinct, the moist, shiny appearance being lost. When the surface of the serum is dry, the growth, as a rule, does not attain any very large size.

These "pure" colonies, when sown in slightly alkaline broth, grow with great vigour; and if a small amount of such a 48 hours' culture is injected into the skin of a guinea-pig, the animal succumbs, with a marked local reaction and distinct symptoms of toxic poisoning very similar to those met with in cases of diphtheria of the human subject. Roux and Yersin demonstrated that the poison was not contained in the bacteria but was produced by the fluid filtered and thrown out by them from and into the nutrient medium. Moreover, they could produce all the toxic symptoms, the local reactions, and even the paralysis which often follows the disease in the human subject, by injecting the culture from which they had previously removed the whole of the diphtheria bacilli by filtration. This cultivation, then, contains a poisonous material, which, incapable of multiplying in the tissues, may be given in carefully graduated doses. If, therefore, there is anything in the theory that tissues may be gradually "acclimatized" to the poisons of these toxic substances, they saw that it should be possible to prove it in connexion with this disease. Behring, going still further, found that the tissues so acclimatized have the power of producing a substance capable of neutralizing the toxin, a substance which, at first confined to the cells, when formed in large quantities overflows into the fluids of the blood, with which it is distributed throughout the body. The bulk of this toxin-neutralizing substance remains in the blood-serum after separation of the cells. In proof of this he showed that (1) if this serum be injected into an animal before it is inoculated with even more than a lethal dose of the diphtheria bacillus or its products, the animal remains perfectly well; (2) a certain quantity of this serum, mixed with diphtheria toxin and injected into a guinea-pig, gives rise to no ill effects; and (3) that even when injected some hours after the bacillus or its toxins, the serum is still capable of neutralizing the action of these substances. In these experiments we have the germ of the present antitoxic treatment which has so materially diminished the percentage mortality in diphtheria. This serum may also be used as a prophylactic agent.

The antitoxic serum as now used is prepared by injecting into the subcutaneous tissues of a horse the products of the diphtheria bacillus. The bacilli, known as living bacilli, are allowed to grow in the blood-serum or blood-plasma, is filtered and heated to a temperature of 68° or 70° C. for one hour. It then contains only a small amount of active toxin, but injected into the horse it renders that animal highly sensitive to the action of neutralizing doses of the toxin, and even induces the production of a considerable amount of antitoxin. This production of antitoxin, however, may be accelerated by subsequent repeated injections, with increasing doses of strong diphtheria toxin, which may be so powerful that up to 4 or 8 of a drop, or even less, is a fatal dose for a medium-sized guinea-pig. The antitoxic serum so prepared may contain 200, 400, 600 or even more "units" of antitoxin per c.c.—the unit being that quantity of antitoxin which, when injected together with a given neutralizing dose of toxin, will prevent paralysis in the rabbit. As for neutralizing doses (the smallest quantity that will kill a 250-grmn. guinea-pig on the fifth day) of toxin for a 250-grmne guinea-pig, that animal continues alive on the fifth day from the injection. This, however, is a somewhat arbitrary and round number of neutralizing power, as it is found that, owing to the complicated structure of the toxin, the neutralizing and the lethal powers do not always go hand in hand; but as the toxin used in testing the antitoxin is always compared with the original standard, accurate results are easily obtained.

Diphtheria, though still prevalent in cities, has now lost many of its terror. In the large hospitals under the Metropolitan Asylums Board the death-rate fell from nearly 40% in 1889 to under 10% in 1903; and if antitoxin be given as soon as the disease is apparent, the mortality is brought down to a very insignificant figure. It has been made plain that as soon as antitoxin came into use the number of cases of paralysis increased rather than diminished. This may be readily understood when it is borne in mind that many patients recover under the use of antitoxin who would undoubtedly have succumbed in the pre-antitoxin days; and it cannot be too strongly insisted that although the antitoxin introduced neutralizes the free toxin and prevents its further action on the tissues, it cannot entirely neutralize that which is already acting on the cells, nor can it make good damage already done before it is injected. Even allowing that antitoxin is not accountable for the whole of the improvement in the percentage mortality statistics since 1896, it has undoubtedly accounted for a very large proportion of recoveries. Antitoxin often cuts short functional albuminuria, but it cannot repair damage already done to the renal epithelium before the antitoxin was given. The clinical evidence of the value of antitoxin in the relief that it affords to the patient is even more important than that derived from the consideration of death rates.

The diphtheria bacillus or its poison acts locally as a caustic and irritant, and generally or constitutionally as a protopathic poison, the most evident lesions produced being degeneration of nerves and muscles, and, in acute cases, changes in the walls of the blood-vessels occurring in the area of the inflammatory process, and in the streptococcus poison. Moreover, it is now clear that secondary complications, which in suppuration, are the remains of the human body, and even the discharge from the wounds of the operation. Infection, as well as the infrequent, which has caused the death of the patient, is the causative agent of the disease.

Tetanus (Lockjaw).—Although tetanus was one of the later diseases to which a definite micro-organismal origin could be assigned, it has long been looked upon as a disease typical of the "septic" group. In 1885 Nicolaier described an organism multiplying outside the body and capable of setting up tetanus, but this was only obtained in pure culture by Kitasato, a Japanese, and by the Italians in 1889. It has a very characteristic series of appearances at different stages of its development. First it grows as long, very slender threads, which rapidly break up into shorter sections from 4 to 5μ in length (see Plate II. fig. 11). In these shorter rods spores may appear on the second or up to the seventh day, according to the temperature at which the growth occurs. The rods then assume a very characteristic pin or drumstick form; they are non-motile, are somewhat rounded at the ends, and at one end the spore, which is of greater diameter than the rod, causes a very considerable expansion. Before sporulation the organisms are distinctly motile, occurring in rods of different lengths, in most cases surrounded by bundles of beautiful flagella, which at a later stage are thrown off, the presence of flagella corresponding very closely with the "motile" period. The bacillus grows best at the temperature of the body; it becomes inactive at 14° C. at the one extreme, and at 42° to 43° C. at the other; in the latter case investigation forms, clubs and branching and degenerated forms, often make their appearance. It is killed by exposure for an hour to a temperature of from 65° to 60° C.; the spores of the bacillus, although very heat-resistant, when the bacilli are killed, they withstand the temperature of boiling water for several minutes. The organism has been found in garden earth, in the excrement of animals—horses—and in dust taken from the streets or from living-rooms, especially when it has been allowed to remain at rest for a considerable period. It has also been demonstrated in, and separated from the pus of wounds (see Plate II. fig. 12) in patients suffering from lockjaw, though it is then invariably found associated with the micro-organisms that give rise to suppuration.

It is important to remember that this bacillus is a strict anaerobe, and can only grow when free oxygen has been removed from the cultivation medium. It may be cultivated in gelatine to which has been added from 2 to 3% of grape-sugar, when, along the lines of the stab culture, it forms a delicate growth, almost like a fine-tree, the tip of which never comes quite to the surface of the gelatine. The most luxuriant growth—evidenced by the longest branches—occurs in the depth of the gelatine away from free oxygen. After a time the
gelatine becomes sticky, and then undergoes slow liquefaction, the growth sinking and leaving the upper layers comparatively clear. This organism is not an obligate parasite, but a facultative; it may grow outside the body and remain alive for long periods.

Lockjaw is most common amongst agricultural labourers, gardeners, soldiers on campaign, in those who go about with bare feet, or who, like young children, are liable to get their knees or hands accidentally wounded by rough contact with the ground. Anything which dezertilizes the tissues—such as cold, bruising, malnutrition, the action of other organisms and their products—may all be predisposing factors, in so far as they place the tissue at a disadvantage and allow of the multiplication and development of the specific bacillus of tetanus. In order to produce the disease, it is not sufficient merely to inoculate tetanus bacilli, especially where resistant animals are concerned: they must be injected along with some of their toxins or with other organisms, the presence of which seems to increase the power of, or assist, the tetanus organism, by diverting the activity of the cells and so allowing the bacillus to develop. The poison formed by this organism resembles the enzymes and diphtheria poison, in that it is destroyed at a temperature of 65° C. in about five minutes, and even at the temperature of the body soon loses its strength, although, when kept on ice and protected from the action of light, it retains its specific properties for months. Though slowly formed, it is tremendously potent, 25 to 50 parts of a drop (the five-millionth part of a c.c.) of the broth in which an active culture has been allowed to grow for three weeks or a month being sufficient to kill a mouse in twenty-four hours, 1/2 of a drop killing a rabbit, 1/8 of a dog, or 1/6 of a drop a fowl or a pigeon; it is from 100 to 400 times as active as strychnine, and 400 times as poisonous as atropine. It has been observed that, quite apart from size, animals exhibit different degrees of susceptibility. Frogs kept at their ordinary temperature are exceedingly insusceptible, but when they are kept warm it is possible to tetanize them, though only after a somewhat prolonged incubation period, such as is met with in very chronic cases of tetanus in the human subject. In experimentally-produced tetanus in horses, which usually commence and are most pronounced in the muscles near the site of inoculation, it was at one time supposed that this was because the poison acted directly upon the nerve terminations, or possibly upon the muscles; but as it is now known that it acts directly on the cells of the central nervous system, it may, as in the case of rabies, find its way along the sympathetic channels of the nerves to those points of the central nervous system with which these nerves are directly connected, spasms occurring in the course of the muscular distribution of the nerves that receive their impulses from the cells of that area. As the amount of toxin introduced may be contained in a very small quantity of fluid and still be very dilute, the local reaction of the connective-tissue cells may be exceedingly slight; consequently a very small wound may allow of the introduction of a strong poisonous dose. Many of the cases of so-called idiopathic tetanus are only idiopathic because the chief visible change, and unless suppuration has taken place, has healed rapidly after the poison has been introduced. In tetanus, as in diphtheria, the organisms producing the poison, if found in the body at all, are developed only at the seat of inoculation; they do not make their way into the surrounding tissues. In this we have an explanation of the fact that all the earlier experiments with the blood from tetanus patients gave absolutely negative results. It is sometimes stated that the production of tetanus toxin in a wound soon ceases, owing to the arrest of the development of the bacillus, even in cases that ultimately succumb to the disease. Roux and Vaillard, however, maintain that no case of tetanus can be treated with any prospect of success unless the focus into which the bacilli have been introduced is freely removed. The antitetanus serum was the first antitoxin serum produced. It is found, however, that though the antitetanic serum is capable of acting as a prophylactic, and of preventing the appearance of tetanic symptoms in animals that are afterwards, or simultaneously, injected with tetanus toxin, it does not give very satisfactory results when it is injected after tetanic symptoms have made their appearance. It would appear that in such cases the tetanus poison has become too firmly bound up with the protoplasm of the nerve cells, and has already done a considerable amount of damage.

(b) More Chronic Infective Diseases (Tissue Parasites).

Tuberculosis.—In no quarter of the field of preventive medicine have more important results accrued from the discovery of a specific infective organism than in the case of Koch's demonstration and separation in pure culture of the tubercle bacillus and the association of this bacillus with the transmission of tuberculosis. In connexion with diagnosis—both directly from observation of the organism in the sputum and urine of tuberculous patients, and indirectly through the tuberculin test, especially on animals—this discovery has been of very great importance; and through a study of the life-history of the bacillus and its relation to animal tissues much has been learned as to the prevention of tuberculosis, and something even as to methods of treatment. One of the great difficulties met with in the earlier periods of the study of tuberculosis was its slow, though persistent, growth. At first cultivations in fluid media were not kept sufficiently long under observation to allow of its growth; it was exceedingly difficult to obtain pure cultures, and then to keep them, and in impure cultures the tubercle bacilli were rapidly overgrown. Taken directly from the body, they do not grow on most of the ordinary media, and it was only when Koch used solidified blood-serum that he succeeded in obtaining pure cultures. Though they may now be demonstrated by what appear to be very simple methods, before these methods were devised it was practically impossible to obtain any satisfactory results.

The principle involved in the staining of the tubercle bacillus is that when once it has taken up fuchsine, or gentian violet, it retains the stain much more firmly than do most organisms and tissues, so that if a specimen be thoroughly stained with fuchsine and then decolorized by a mineral acid—25% of sulphuric acid, say—although the colour is washed out of the tissues and most other organisms, the tubercle bacilli retain it; and even after the section has been stained with methylene-blue, to bring the other tissues and organisms into view, these bacilli still remain bright red, and stand out prominently on a blue background. If a small fragment of tuberculous tissue be pounded in a sterile mortar and smeared over the surface of impregnated blood-serum solidified at a comparatively low temperature, and if evaporation be prevented, dry scaly growths make their appearance at the end of some fourteen days. If these be reincubated through several generations, they ultimately assume a more saprophagic character, and will grow in broth containing 5% of glycerin, or on a peptone beef-agar to which a similar quantity of glycerin has been added. On these media the tubercle bacillus grows more luxuriantly, though after a time its virulence appears to be diminished. On blood-serum its virulence is preserved for long periods. The tubercle bacillus can be recovered from decubitus tissues or in cultivations as a delicate rod or thread 1-5 to 2-5μ in length and about 0-2 to 0-5μ in thickness (see Plate II., fig. 15). It is usually slightly curved, and two rods may be arranged end to end at an open angle. There is some doubt as to whether tubercel bacilli contain spores, but little masses of deeply-stained protoplasm can be seen, alternating with clear spaces within the sheath; these clear spaces have been held to be spores. This organism is found in the lungs and sputum in various forms of consumption; it is met with in tuberculous ulcers of the intestine, in the lymph spaces around the vessels in tuberculous meningitis, in tuberculous nodules in all parts of the body, and in tuberculous disease of the skin—lupus. It is found also in the tuberculous lesions of animals; in the throat-glands, tonsils, spleen and bones of the pig; in the spleen of the horse; and in the lungs and pleura of the cow. Tuberculosis may be produced artificially by injecting the tubercle bacillus into animals, some being much more susceptible than others. Milk drawn from an udder in which there are breaking-down tuberculous foci, may contain an enormous
783

PARASITIC DISEASES

number of active tubercle bacilli; and pigs fed upon this milk develop a typical tuberculosis, commencing in the glands of the throat, which can be traced from part to part of the body. The utmost precision of diagnosis is not always possible, but the heat which takes place in the subject is evidently also in the subject; and a sufficient number of cases are now on record to show that the swallowing of tuberculous material is a cause of tuberculosis, especially amongst children and adolescents. Inhaled tubercle bacilli from the recently-dried sputum of phthisical patients, like milk derived from tuberculous udders, may set up tuberculosis of the lungs or of the alimentary tract, especially when the epithelial layer is unhealthy or imperfect. The two main causes of the prevalence of tuberculosis in the human subject are: (1) tubercle bacilli may become so modified that they can flourish saprophytically; as yet it has not been possible to trace the exact conditions under which they live, but we are gradually coming to recognize that, although when they come from the body they are almost obligate parasites, they may gradually acquire saprophytic characters. (2) Many of the domestic animals are readily infected with tuberculosis, and in turn may become additional centres from which infection may radiate.

Koch's tuberculin has been of inestimable value in the early diagnosis of tuberculosis, especially in animals.

Tuberculin, from which the tuberculin test derives its name, consists of the products of the tubercle bacillus when grown for a month or six weeks in peptone meat-broth to which a small proportion, say 5 or 6% of glycérin has been added. The tubercle bacillus and its derivatives are temperature sensitive, especially when in a partially liquid state, and are not demonstrable, and completely by filtration through a Berkfield or Pasteur-Chamberland filter. If a large dose of this filtered fluid be injected under the skin of a healthy man or brute, it is possible to produce some of the symptoms of tuberculosis, such as swelling of the injected area and low-grade fever. It is evident that in a similar patient suffering from tuberculosis a very much smaller dose (one which does not affect the healthy individual in the slightest degree) is sufficient to bring about the characteristic swelling and rise of temperature, that is, the false test reaction, especially when carefully attended to. The reaction is only obtained under certain well-defined conditions. Driven animals seldom, if ever, react properly. Cattle to be tested should be allowed to remain at rest for some time before the test is condemned, especially when the test results are not clearly positive. After an injection of tuberculin into the subcutaneous tissues (usually in front of the shoulder or on the chest-wall) they should be kept under the same conditions and should be watched very carefully; the temperature is taken every hour or two; the test is regarded as negative if the temperature remains at or above a certain standard, say 101° F., but if it falls below 100° F. within three hours of an initial rise, the test is regarded as positive, especially when the first reaction is two hours or more after the injection. If the temperature remains between these points the case is a doubtful one, and, according to Sir John M'Fadyean, should be retested at the end of a month. It is interesting to note that the test is not trustworthy in the case of tuberculosis of the skin, in which the granulation stage is very rapid, especially when the skin is already high—103° F. In such cases, however, it is an easy matter to diagnose the disease by the ordinary clinical methods. At first observations were raised to this test on two grounds: (1) the bacilli, when injected into the skin, are capable of the multiplication, even if a small number of bacilli be injected subcutaneously into a tuberculous patient in whom, however, the tubercle bacilli may be demonstrable, the temperature begins to rise in six or eight hours and continues to rise for twelve hours or, in rare cases, for an even longer period, and it is considered sufficient to indicate the presence of the disease. Along with this there is usually some swelling and tenderness, with perhaps redness at the point of injection, whilst there is also some evidence of a vascular character in other parts of the body. An important method of applying tuberculin as a diagnostic reagent is that of Pirquet, who, after diluting old tuberculin with two parts of normal saline solution and one part of 5% carbolic acid, places a drop of the mixture on the skin and the reaction can be observed. The results are a "small dental burr." The skin is similarly treated with normal saline some 2 or 3 in. away from that at which the tuberculin is used. In the tuberculin area a little papule develops, which may become a vesicle, surrounded by a line of small fuel on the skin. The area, and remains. However, if a small drop of tuberculin is dropped into the conjunctival sac of one eye; this is followed by a mild attack of conjunctivitis or infiltration of the eye in the tuberculous patient, whilst in the healthy patient no effect is produced. Thus Dr. Pirquet's test appears to be of considerable value, it fails to give any information in cases of advanced tuberculosis, or of general miliary tuberculosis and of tuberculous meningitis. It certainly possesses one great advantage over the others—it does not give any reaction in cases of miliary tuberculosis in persons clinically sound and healthy. The inflation of the eye may, however, be so acute, especially where strong solutions of tuberculin are used, that considerable damage may be done, more especially should there be any foreign disease of the eye. It must be remembered that these tests the exhibition of tuberculin increases for a time the sensis- tiveness of the patient each time it is administered. It sets up a negative phase, as already described, and renders the patient more susceptible to the disease. It is believed that these tests are accompanied with, and at the present time Koch's two tuberculins—especially his new tuberculin—hold the field. The "old tuberculin" consists of the glycérin broth culture of the tubercle bacilli mentioned above. The new tuberculin consists of the centrifugalized deposit from a saline solution of the extract of the triturated dead tubercle bacilli; this is stored in small tubes, each containing two milligrammes of solid substance. This is diluted with distilled water containing 20% of glycérin, great care being taken to maintain the sterility of the solution. The dose is usually from 100 to 1000 of a milligramme for an adult, increasing to 10000; according to Sir A. Wright it should not go beyond this.

Perhaps no one has done more to rehabilitate the tuberculin treatment than Sir Almroth Wright, who after a long series of experiments devised what he called the tuberculo-opsinic index, about which a few words may be of interest. It is well-known that the blood contains cells which destroy bacteria into their substance and there digesting them. This, the so-called "phagocytic power" of Metchnikoff, was found to vary somewhat under different conditions, and Wright set himself to determine the factors which influenced this power and its variability. He found that the white blood corpuscles, the polymorphonuclear cells, whether from healthy or tuberculosis patients, always showed practically the same phagocytic activity when mixed together in equal parts with a saline solution, even when the latter has been taken from a healthy patient. If, however, corpuscles from the same individuals, whether healthy or tuberculous, were allowed to act upon the bacilli in the presence of serum drawn from a tuberculous patient, one of three things might happen: (1) the bacilli might be taken up in smaller numbers than in the above series of experiments; (2) they might be taken up in larger numbers; or (3) they might be taken up in what might be called normal numbers. In (1) and (2) Wright holds that the phagocytic power of the serum of tuberculosis is the evidence is negative. He found, however, that when a dose of tuberculin was injected into a tuberculous patient there was a distinct fall in the number of tubercle bacilli taken up by the leukocytes compared with the serum of the patient. This condition Wright speaks of as the "negative phase." Increased phagocytic activity of the cells is associated with what is spoken of as the positive phase. The theory is that the blood serum has the power of preparing bacteria to be eaten by the phagocytes in the same sense that boiling, says prepare food for ready digestion by the human subject, and Wright applied the term opsonin to the unknown constituent or complex of constituents of the serum that
exerts this action upon the bacteria. The opsonic index is obtained by comparing the average number of bacilli taken up by, say, 100 leucocytes, to which the serum from a tuberculous patient has been added, with the number of bacteria taken up by a hundred similar concentrations to which normal serum has been added. The ratio between the two giving the opsonic index. Wright maintains that after the injection of small doses of tuberculin during a negative phase which first appears, i.e. whilst there is a fall in the number of bacilli in the blood, the number of bacilli is much more susceptible than before to the attacks of the tubercle bacillus. Following this, however, there is a gradual rise in the opsonic index until it passes the normal and the patient enters a positive phase, during which the susceptibility to the attacks of the bacilli is considerably diminished. When the effects of this dose are passing off a fresh injection should be made; this again induces a negative phase, but one that should not be so marked as in the first instance, whilst the positive phase which succeeds should be still more marked than that first obtained. This can be repeated systematically and regularly the patient should begin, and continue, to improve. The difficulties involved in the determination of the opsonic index are, however, exceedingly great, and the personal factor enters so largely so that some observers are very doubtful as to the practical utility of this method. In Wright's hands, however, and in the hands of those who work with him, very satisfactory results are obtained. The tuberculin treatment, fortunately, does not stand or fall by the success of the opsonic index determination, especially as most valuable information as to the course of the disease and the effects of the tuberculin may be obtained by a study of the daily temperature and of the various constitutional evidences of the disease. Tuberculin should not be injected more frequently than about once in 10 or 14 days, and it is well not to increase the dose too rapidly. Wherever the temperature continues high, even a degree between 37 and 38 C., this may be a positive sign that it is not tuberculin, nor does it seem to be of any great value where the disease is making rapid headway or has become generalized, especially where there is meningitis or bleeding from the lungs. It is interesting to note, in connection with the opsonic index, that in non-tuberculous subjects the administration of a small dose of tuberculin is followed by no negative phase such as is met with in the tuberculous subject. The phagocytic power of the white blood corpuscles is determined by the ingestion of whole tubercle bacilli. The index falls whenever the bacillus is mixed with equal parts of a standard emulsion of tubercle bacilli and blood serum incubated in fine glass tubes for 15 minutes at a temperature of 37 C. If the period of incubation is much shorter than 15 minutes, the pathogonic power is less; and if the period be longer so many organisms are taken up that it becomes impossible to dif- ferentiate two sets of sera.

As an example we might adduce the following. Taking a tuberculous sputum containing 50-100 leucocytes per c.mm., the number of bacilli was determined by counting the number of bacilli per leucocyte; with the addition of 10 c.c. of serum and 10 c.c. of corpuscles and 10 c.c. of tubercle bacilli, the number of bacilli per leucocyte in the same number of cells was determined. These figures were then used to calculate the opsonic index obtained, which was 1 + 3 = 0.6 = opsonic index.

Leprosy.—Armauer Hansen in 1871, and Neisser in 1881, described a “leprosy bacillus” corresponding in size and in certain points of staining reaction to the tubercle bacillus, and it is now generally accepted that this bacillus is the direct and specific causal agent of leprosy. The discovery of this organism paved the way for the proof that the tubercular and anesthetic forms of leprosy are essentially the same disease, or rather are the manifestations of the action of a common organism attacking different series of tissues.

To demonstrate the presence of the leprosy bacillus, take an indiarubber ring firmly around the base of one of the leprosy tusks, which is represented as somewhat of a white color. If the ring is made tight enough, but not tightly, the bacillus will be driven out, leaving the nodule pale, make a puncture with the point of a sharp knife. From this puncture a clear fluid exudes; this, dried on a coverslip, will show, stained with carbol-fuchsin, and rapidly decolorized with a weak mineral acid, shows bacilli stained red and very like tubercle bacilli; they differ from that organism, however, in that they are somewhat shorter, and that if the acid be too strong or be allowed to act on them for too long a time, the colour is discharged from them much more readily. These organisms, which are from 4 to 6 x 1 in length and 0.3-4 in breadth, are as a rule more rigid and more pointed than are the tubercle bacilli (see Plate II., fig. 16). It is doubtful whether they form spores. They are found in large numbers lying embedded in a kind of gelatinous substance in the lymphatics of the skin, in certain cells of which they appear to be taken up.

It is curious that these bacilli affect specially the skin and nerves, but rarely the lungs and serous membranes, thus being in sharp contrast to the tubercle bacillus, which affects the latter very frequently and the former very rarely. They are seldom found in the blood, though they have been described as occurring there in the later stages of the disease. It is stated that leprosy has been inoculated directly into the human subject, the patient dying some five or six years after inoculation; but up to the present no pure culture of the leprosia bacillus has been obtained; it has therefore been impossible to produce the disease by the inoculation of the bacillus only. What evidence we have at our disposal, however, is all in favour of the transmissibility of the disease from patient to patient and through the agency of the leprosy bacillus. None of the numerous non-bacillary theories of leprosy account at all satisfactorily for this transmissibility of the disease, for its progressive nature, and for the peculiar series of histological changes that are met with in various parts and organs of the leprous body. Leprosy occurs in all climates. It is found where no fish diet can be obtained, and where pork and rice are never used, though to these substances has been assigned the power of giving rise to the disease. Locality appears to influence it but little, and with improved sanitation and increased cleanliness it is being gradually eradicated. The only fact or that is common in all forms of leprosy, and is met with in every case, is the specific bacillus; and in spite of the fact that it has yet been found impossible to trace the method of transmission, we must from what is known of the presence and action of bacilli, in other diseases, especially in tuberculosis, assign to the leprosy bacillus the rôle of leprosy-producer, until much stronger evidence than has yet been obtained can be brought forward in favour of any of the numerous other causes that have been assigned. Two cases are recorded in which people have contracted leprosy from picking their fingers with needles whilst sewing a leper's clothes; and a man who had never been out of Dublin is said to have contracted the disease by sleeping with his brother, a soldier who had returned from India suffering from leprosy.

Glanders.—Farcy in the human subject resembles the same disease experimentally produced in animals with material from a glandered animal, and as there is no pathological distinction between the two, from the aetiological standpoint, they may be considered together. If the pus from a glanders abscess be mixed with a little sterile saline solution and spread over the cut surface of a boiled potato kept at the body-temperature, bright yellow or honey-coloured, thick, moist-looking colonies grow very rapidly and luxuriantly. These colonies gradually become darker in colour, until they assume a cafe-au-lait, or even a chocolate, tint. On examining one of them microscopically, it is found to be made up of bacilli 2 to 52 long and 4 to 3 of their own length broad (see Plate I., fig. 2 and fig. 6). The bacillus is usually straight or slightly curved and rounded at one end; it appears to be non-motile. As first pointed out by Loeffler and Schütz, when a portion of a culture is inoculated subcutaneously, typical farcy, with the acute septicemia or blood-poisoning so characteristic of certain cases of glanders and farcy, is the result. The human subject is usually inoculated through wounds or scratches, or through the application of the nasal discharge of a glandered animal to the mucous membrane of the nose or mouth. Man is not specially susceptible, white mice and house mice, unless previously fed on sugar or with phosphorid, are unaffected by inoculation of the glanders bacillus. The pigeon is the only bird in which glanders has been produced. Lions and tigers are said to contract the disease, and to take it in a very severe and
Parasitic Diseases

785

rapidly fatal form. The glanders organism soon loses its virulence and even its vitality. Dry, it dies in about ten days; placed in distilled water, in about five days; but kept moist, or on culture media, it retains its vitality for about a month, although its activity soon becomes considerably lessened. These bacilli are readily killed at a temperature of 55°C.; they can pass through the kidneys, even when there is no lesion to be made out either with the naked eye or under the microscope (Sherrington and Bonome).

The glanders bacillus grows best in the presence of oxygen, but it may grow anaerobically; it then appears to have the power of forming toxin, either more in quantity or of greater activity than when it has access to a free supply of oxygen. This poison (mallein) is used for the purpose of diagnosing the presence of glanders. A cultivation is made in peptonized bouillon to which a small portion of glycerin has been added. The bacillus is allowed to grow and multiply at the temperature of the body for a month or six weeks; the organisms are then killed by heat and 0.5% carboxylic acid is added. The cultivation is then filtered through a porcelain filter in order to remove the bodies of the bacilli, and the resulting fluid, clear and amber-coloured, should have the power, when injected in quantities of 1 c.c., of giving the specific reaction in an animal suffering from glanders; in a healthy animal 6 c.c. will give no reaction. The suspected animal should be kept at rest and in a warm stable for twenty-four to forty-eight hours before the test is applied. The temperature should be normal, as no proper reaction is obtained in an animal in which the temperature is high. This reaction, which is a very definite one, consists in a rise of temperature of from 2° to 4° F., and the appearance of a swelling of from 3 to 4 in. in diameter and from 1 to 1½ in. in height, before the sixteenth or eighteenth hour; this swelling should continue to increase for some hours. It has been suggested that the injection of 1/10 to 1/5 c.c. of mallein, at intervals of two or three days, may be used with advantage in the treatment of glanders. Glandered horses seem to improve under this treatment, and the pseudotuberculosis may react even to much larger doses of mallein. The mallein test has revealed the fact that glanders is a far more common and more widespread disease than was at one time supposed.

II.—To Higher Vegetable Parasites

Actinomyces.—This disease is very prevalent in certain low-lying districts, especially amongst cattle, giving rise to the condition known as "sarcoma," "wooden tongue," "wens," "bony growths on the jaw," &c. It is characterized by the presence of a fungus, which, at first growing in the form of long slender threads that may be broken up into short rods and cocci, ultimately, as the result of a degenerative process, assumes the form of a "ray-fungus," in which a series of club-like rays are arranged around a common centre (see Plate I., fig. 5). It is probably a streptothrix—Stréptothrix Försteri. Numerous cases have been observed in the human subject. Suppuration and the formation of fistulous openings, surrounded by exuberant granulations, "proud flesh," usually supervene where it is growing and multiplying in the tissues of the human body, and in the pus discharged are yellowish green or reddish brown points, each made up of a central irregular mycelium composed of short rods and spores, along with the clubs already mentioned. The mycelial threads may reach a considerable length (20 to 100µ); some of them become thicker, and are thus differentiated from the rest; the peripheral club is the result of swelling of the sheath; the filaments nearer the centre of the mycelial mass contain spores, which measure from 1 to 2µ in diameter. This fungus appears to lead a saprophytic existence, but it has the power of living in the tissues of the animal body, to which it makes its way through or around carious or loose teeth, or through abrasions of the tongue or tonsils. After the above positions, the abdomen, especially near the veriform appendix, is a special seat of infection, or in some cases the thorax, the lesions being traceable downwards from the neck. Any of the abdominal or thoracic organs may thus be affected. The process spreads somewhat slowly, but once started may extend in any direction, its track being marked by the formation of a large quantity of fibrous tissue, often around a long fistula. In the more recent growths, and in solid organs, or tissues of some size, containing a soft semi-purulent cheesy-looking material, may be found, this mass in some cases being surrounded by dense fibrous tissue. When once a sinus is formed the diagnosis is easy, but before this the disease, where tumours of considerable size are rapidly formed, may readily be mistaken for sarcoma, or when the lungs are affected, for tuberculosis, especially as bronchitis and pleuritic effusion are frequently associated with both actinomyces and tuberculosis.

Myceloma, the Madura foot of India, is a disease very similar to actinomyces, and, like that disease, is produced by a somewhat characteristic streptothrix. It usually attacks the feet and legs, however, and appears to be the result of infection through injured tissues. Under certain conditions and in long-standing cases the fungus appears to become pigmented (black) and degenerated.

Other forms of fungus disease or Mycoses are described. Aspergillosis, or pigeon-breeder's disease, is the result of infection with the Aspergillus fumigatus. Certain tumours appear to be the result of the action of a yeast, Blastomyces or Saccharomyces. The spores of the Penicilium glaucum, and of some of the Mucorales, are also said to have the power of setting up irritation, which may end in the formation of a so-called granuloma or granulation tissue tumour. These, however, are comparatively rare.

B.—Diseases due to Animal Parasites.

I.—To Protozoa

Malaria.—Following Laveran's discovery, in 1880, of a parasite in the blood of patients suffering from malaria, our knowledge of this and similar diseases has increased by leaps and bounds, and most important questions concerning tropical diseases have now been cleared up. Numerous observations have been carried out with the object of determining the parasitic forms found in different forms of malaria—the tertian, quartan, and septique, or septimal, malaria. In each of these, in the red blood corpuscles, a series of developmental stages of the parasite from a small pale translucent amoeboid form may be followed. This small body first becomes lobulated, nucleated and pigmented; it then, after assuming a more or less marked rosette-shape with a deeply pigmented centre, breaks up into a series of small, rounded, hyaline masses of protoplasm, each of which has a central bright point. The number of these, contained in a kind of capsule, varies from 8 to 10 in the tertian, and from 12 to 20 in the tertian and aestivo-autumnal forms. There are certain differences in the arrangement of the pigment, which is present in larger quantities and distributed over a wider area in the somewhat larger parasites that are found in the tertian and quartan fevers. In the parasite of the aestivo-autumnal fever the pigment is usually found in minute dots, dividing near the pole at the point of division of the organism, along with it in the earlier stages (see Plate I., fig. 5). Here, too, the rosette form is also said to exist as the pleocyst of tertian fever, and in the latter is not so distinct as in the quartan parasites. These dividing forms make their appearance immediately before the onset of a malarial paroxysm, and their presence is diagnostic. The process of division goes on especially in the blood-forming organs, and is therefore met with more frequently in the spleen and in bone-marrow than in any other situation. The parasites, at certain stages of their development, may escape from the red blood corpuscles, in which case (especially when exposed to the air for a few minutes) they send out long processes of protoplasm and become very active, moving about in the plasma and between the corpuscles, sometimes losing their processes, which, however, continue in active movement. In the aestivo-autumnal fever curious crescent-shaped or ovoid bodies were amongst the first of the parasitic organisms described as occurring in the blood, in the red corpuscles of which they develop. Manson maintains that from these arise the flagellate forms, all of which, he thinks, are developed in order that the life of the malarial parasite may be continued outside the human body. It is probable that most of the pigment found in the organs taken from
PARASITIC DISEASES

malarial patients is derived from red blood corpuscles broken down by the malarial parasites; many of these, in turn, are devoured by leucocytes, which in malarial blood are usually greatly increased in number, and frequently contain much pigment, which they have obtained either directly from the fluid plasma or from the pigmented parasitic organism. The work recently carried out by Bruce on the tsetse-fly parasite, by A. J. Smith on Texas fever, and by W. S. Thayer and Hewison on the blood parasites of birds, has opened up the way for the further study of the malarial parasites outside the human body. There can be no doubt as to the close relation of the multiplication and sporulation of the malarial parasite with the ague paroxysm: the anaemia results from the breaking down of blood corpuscles. Toxic substances are present in the blood during the setting free of the spores; of this we have proof in the increased toxicity of the urine during the paroxysmal stages of the disease; moreover necrotic areas, similar to those found in acute toxic fevers produced by other micro-organisms, are met with. It is well to bear in mind that the accumulation of debris of parasites and corpuscles in the capillaries may be an additional factor in this necrosis, especially when to this is added the interference of nutrition necessarily involved by the impoverished condition of the malarial blood. It is interesting to note that, although, as pointed out by Nuttall, the Italian and Tirolese peasants have long been firmly of the opinion that malaria is transmitted through the mosquito, and although the American, Dr Josiah Nott, in 1848 referred to malaria as if the mosquito theory had already been advanced, little attention was given to this question by most observers. Still earlier, Rasori (in 1846) had stated that "for many years I have held the opinion that intermittent fevers are produced by parasites, which renew the paroxysm by the act of their reproduction, which recurs more or less rapidly according to the variety of the species"; and this appears to be the first well-authenticated reference to this subject. Nuttall, who gives an excellent summary of the literature on the mosquito hypothesis of malaria, assigns to King the honour of again drawing attention to this question. Lavran in 1831, Koch in 1852, Manson in 1854, Bignami and Mendini in 1866, and Grassi, Bignami and Bastianelli in 1868 all turned their attention to this hypothesis. Manson, basing his hypothesis upon what he had observed as regards the transmission of Filaria by the mosquito, suggested a series of experiments to Major Ronald Ross. These were carried out in 1895, when it was found that in mosquitoes that had taken up blood containing ameboid parasites, crescents, which were first described as cells, appeared in the stomach-wall after four or five days; these contained a number of stationary vacuoles and pigment granules, ten to twenty in number, bunched together or distributed in lines. Grassi, Bignami and Bastianelli confirm and supplement Ross's observations; they find that Anopheles claviger, taking the blood from a patient suffering from malaria, soon develops haemoplasmodia in the intestine. These parasites are then found between the muscular fibres of the stomach; they increase in size, become pigmented, and more and more vacuolated, until they project into the body-cavity. On the sixth day these large spheres contain an enormous number of red flagellates, which may, by their 'silver dust' appearance, be distinctly seen in the blood. On the seventh day numerous flagellates, arranged in rows around several foci, are seen. They are very delicate, are stained with difficulty, and appear to be perfectly independent of each other, though grouped within a capsule. After the capsule has ruptured, these thread-like "sporozoites," escaping into the body-cavity, gradually make their way to and accumulate in the cells or tubules of the salivary glands, whence their passage through the proboscis into the human blood is easily understood.

Thus two phases or cycles of existence have been demonstrated—one within the human body, the second in the mosquito. Development of the Malarial Parasite. That within the human body appears to be capable of going on almost indefinitely as long as the patient lives, but that in the mosquito appears to be an offshoot or an intermediate stage. The minute specks of protothaxia, the amoebulae, which have already been described as occurring in the red blood corpuscles of the higher animals, increase in size, take up blood pigment, probably from the red corpuscles, and then become developed into sporocytes or gametocytes. The sporocyte is the form which, remaining in the body, ultimately breaks up, as already seen, into a series of minute spores or amoebulae, which in turn go through the same cycle again, increasing in size and forming spores, and so on indefinitely. Gametocytes (the true sexual form) are in certain species, to outward appearance, very similar to the sporocyte, but in others they assume the crescentic shape, and can thus be recognized. The male cell resembles the female cell very closely, except that the protoplasm is hyaline and homogeneous-looking, whilst that of the female cell is granular. It has already been noted that when the blood is withdrawn from the body certain of the malarial parasites become flagellated. These flagella may be looked upon as sperm elements, which, forming in the male gametocyte, are extruded from that cell, and, once set free, seek out the granular female gametocytes. A single flagellum becomes attached to a small projection that appears on the female cell; it then makes its way into the protoplasm of the female cell, and by rapid streaming movements are then developed. In certain species the female cell is somewhat elongated, and may be peculiarly constricted. It becomes motile, and appears to have the power of piercing the tissues. In this way the first stages of development in the mosquito are passed. The gametocytes, taken along with the blood into the stomach of this insect, pass through the various phases above mentioned, though the zygote form of the human malarial parasite has not yet been traced. In the blood of a patient bitten by an infected mosquito the ordinary malarial parasite may be demonstrated without any difficulty at the end of a week or ten days, and the cycle recommences.

This theory, now no longer a hypothesis, in which the mosquito acts as an intermediary host for one stage of the parasite and transmits the parasite to man, affords an explanation of many apparently anomalous conditions associated with the transmission of malaria, whilst it harmonizes with many facts which, though frequently observed, were very difficult of explanation. Malaria was supposed to be associated with watery exhalations and with the fall of dew, but a wall or a row of trees was seemingly quite sufficient to prevent the passage of infection. It was met with on wet soils, on broken ground, in marshes, swamps and jungles; on the other hand, it was supposed to be due to the poisonous exhalations from rocks. All this is now explained by the fact that these are the positions in which mosquitoes occur: wherever there are stagnant pools, even of a temporary nature, mosquitoes may breed. It has been observed that although the malarial "miasma" never produces any ill effects in patients living at more than a few feet from the surface of the ground, malaria may be found at a height of from 7000 to 9000 ft. above sea-level; and the fact that a belt of trees or a wall will stop the passage of the poison is readily explicable on the mosquito theory. These insects are incapable, owing to their limited power of flight, of rising more than a few feet from the ground, and they make their way through a belt of trees of even moderate thickness. Broken ground pools are common of occurrence, and afford the conditions for the development of the mosquito, and infected tools used in one area may easily convey the ova to another. All these facts afford further support of this theory. The conditions of climate under which malaria is most rife are those which are most suitable for the development of the mosquito. The protection afforded by fires, the recognized value of mosquito curtains, the simultaneous disappearance of Anopheles and malaria on the complete draining of a neighbourhood, the coincidence of malaria and mosquitoes, and the protection afforded by large expanses of water near walls and trees are also important in this connexion.

The mosquitoes specially associated with the transmission of malaria in the human subject belong apparently to the genus

Development of the Malarial Parasite.
Anopheles. *Anopheles claviger* (maculipennis) and *Anopheles bifurcarius* both are found in Great Britain; *Anopheles pictus* is also found in other species found in Europe, but so far not in Great Britain. A member of the genus Culex, the grey mosquito or *Culex fatigans*, is the intermediate host of the protozoa of birds, on which many of the intermediate phases of the life-history of these parasites have been studied. Ross describes a dappled-wing mosquito as the one with which he performed his experiments on birds in India. *Anopheles claviger* is interesting in view of the former prevalence of malaria in Great Britain.

The remedy for malaria appears to be the removal or spoiling of the breeding grounds of the mosquito, thorough drainage of pools and puddles, or, where this cannot be easily effected, the throwing of a certain amount "of kerosene on the surface of these pools" (Nuttall).

Amoebic Dysentery.—In addition to the dysentery set up by bacteria, a form—amoebic dysentery or amoebic enteritis—has been described which is said to be due to an animal parasite, and it has been proposed to separate the various types of dysentery according to their aetiology, in which case the amoebic group is probably more specific than any other. The amoeba (*Amoeba dysenteriae, Entamoeba histolytica*, of Schaudinn) supposed to give rise to this condition was first described by Lösch in 1875. Since then this amoeba has been described either as a harmless parasite or as a cause of dysentery in Europe, Africa, the United States and in Brazil, and more recently in India. This organism, which is usually placed amongst the rhizopods, consists of a small rounded, ovoid or pear-shaped globule of protoplasm, varying in size from 6 to 40 μ, though, as Lafleur points out, these limits are seldom reached, the organism being usually from one and a half to three times the diameter of a leucocyte—from 12 to 26 μ (see Plate II., fig. 19). Its margins are well defined, and the body appears to consist of a granular inner portion and a homogeneous outer portion, the latter being somewhat lighter in colour than the inner; in the resting stage this division cannot be made out. The organism appears to pass through at least two phases, one corresponding to a cyst in the other to an amoeboid stage. In the latter stage, if the organism be examined on a warm stage, it is seen to send out processes, and, as in other amoebae, vacuoles may be seen as clear spaces lying in the granular and darker-coloured inner protoplasm. In the small vacuoles a deeply stained point may be seen. These vacuoles may be extruded through the ectoplasm. In some cases the vacuoles are so numerous that they occupy the whole of the space usually occupied by the granular protoplasm, and are merely surrounded by a zone of variable thickness, which "has the appearance of finely granular glass of a distinctly pale green tint" (Lafleur). In the cystic stage a nucleus which appears amongst the vacuoles may be made out, usually towards one side of the amoeba. This nucleus is of considerable size, i.e., nearly as large as a red blood corpuscle, and is readily distinguishable from the surrounding protoplasm. When stained by the Benzol method (safranin and light green) a more deeply staining nucleus may be observed; in the vacuoles the nucleus is often seen when stained by this method, but it is always difficult to obtain well-stained specimens of this organism. If these amoebae can be kept under observation for some time evidence of amitotic division may sometimes be seen. Red blood corpuscles are often engulfed by this amoeba, as are also micrococcii and bacilli. The movements of the amoebae are most active at a temperature of about 90° to 98° F. From the fact that pigment is contained in these organisms, it is supposed that they take in the red blood corpuscles as nutritive material, and that other substances may be taken in to serve a similar purpose. Nothing is known of the method of multiplication of the amoeba, but it is supposed that it may be both by fission and by spore formation. These organisms are present in the early stage of the acute disease, and disappear at the later stages. Perhaps of some importance is the fact that the abscesses found in the liver and lung, which occur so frequently in cases of dysentery, usually contain, especially in the portions immediately adjoining the suppurring mass, a considerable number of these amoebae. In the very small abscesses the amoebae are numerous and active, and occupy the whole of the interior of the lesion. It is quite possible that this swarming of the capillaries with amoebae is the cause both of the hemorrhages and of the small areas of necrosed tissue, the supply of nutrient being cut off from the liver cells and from the lung tissues, and that suppuration occurs only as a secondary process, though Councilman and Lafleur maintain that the amoeba itself is the primary cause of suppuration. It is possible, of course, that the suppuration is due to the action of pus-forming organisms conveyed along with, or following, the amoeba, as we know that the growth of suppurring organisms can go on in dead tissues when these organisms have no chance of surviving in the healthy tissues and fluids of the body. Lafleur holds that the amoeba forms a toxic substance which exerts a direct devitalizing effect on the liver cells, and that the amoeba itself causes suppuration. The abscesses in the lung, which invariably extend directly from the liver and occur at the base of the right lung, also contain these amoebae. For these reasons this organism is looked upon as the cause of dysentery and of certain forms of dysenteric abscess.

They differ from the *Entamoeba coli*—often met with in the intestine—which has a more distinct nucleus containing larger chromatin masses and is surrounded by a highly refractive nuclear membrane. Further, in the *Entamoeba coli* the cytoplasm is of the same character throughout, there being no differentiation into ectoplasm and endoplasm. *Amoeba histolytica* is often met with in a "resting phase," in which the nucleus is less distinctly marked, and may consist of small masses of chromatin distributed throughout the cell or penetrating small buds formed on the surface. Around each of these buds, three, four or more, a highly refractive cyst wall is formed, the cysts becoming separated from the rest of the cell, the remnant of which undergoes disintegration. These cysts are extremely resistant, and probably maintain the continuity of the species outside the body.

In the active phase, the amoeboid form appears able by its tough membranous pseudopodia to pass through the mucous membrane of the large intestine, especially the rectum, the lower part of the ileum and the flexures. Once it is ensconced in these tissues, small soft oedematous looking swellings soon appear on the mucous surface. Marshall points out that the amoeba probably reaches the liver by the portal circulation from the dysenteric lesions in which the amoeba are found. Other observers maintain that the amoeba may pass through the walls of the intestine, through the peritoneal cavity, and so on to the liver where they give rise to typical abscesses.

**Syphilis.**—It has long been recognized that syphilis is a specific infective disease, but although characterized by fever, anaemia, and increased growths of tissue followed by rapid degeneration and ulceration of tissue, it is only within quite recent years that a definite parasitic organism, present in all cases of typical syphilis, has been isolated and studied. Schaudinn and Hoffmann, followed by Metchnikoff and others, have described as of this organism a spiral or screw-shaped organism in which are seen from half a dozen to a dozen well-defined, short, regular, almost semicircular curves. This organism, when examined fresh, in normal or physiological salt solution, exhibits active screw-like movements as it rotates along its long axis; from time to time it becomes more or less bow-shaped and then straightens out, while moving about from point to point in the field of the microscope. It is not very strongly refractile, and can only be examined properly with the aid of special central illumination and in the presence of minute particles, by the movements of which the organism is more readily traced.

In order to obtain this organism for demonstration it is a good plan to wash the primary or secondary syphilitic sore thoroughly with alcohol; some of the clear fluid is then collected on a coverslip; or, perhaps better still, the lymphatic gland nearest to one of these sores may be punctured with a hypodermic needle, the fluid being driven out on to a slide on which some normal saline solution has been placed. When the organism has been examined alive the film may be carefully dried and then stained by Giemsa's

---

**PARASITIC DISEASES**

---
modification of the Romanowsky stain (see Plate I, fig. 1). This stain, which may be obtained ready prepared from Grüber, of Leipzig, under the name of "Giemsa'sche Lösung für die Romanowsky Färbung," is made as follows: Azur II–eosin compound, 5 g.; a little absolute alcohol (Merck's "for analysis"), and transfer to a clean, dry, well stoppered bottle. Pour three or four drops of this stain on to the prepared film (blood, bone, marrow, &c.) and run from side to side. After about a half minute add six or eight drops of distilled water, and mix thoroughly by moving the slide or cover-glass. Allow the stain to act for five minutes longer or, if the film be thick, for ten. Wash with distilled water, leaving a drop or two on the glass for about a minute. Examine at once or after drying without heat and mounting in xylol balsam.

These peculiar parasitic bodies appear as deeply stained points, rounded, oval or cockle-shaped, lying free or grouped in the large endothelial cells of the spleen. Examined under a magnification of 1000 diameters they are found to measure from 3·5 to 2·5 μ, or even less, in diameter. Their protoplasm is stained, somewhat unequally, light blue; and from this light blue background they are distinctly visible. A very deeply stained violet coloration of unequal size and shape is seen more prominently; the smaller of these is more deeply stained than the larger, is thinner, somewhat more elongated or rod-shaped, and parallel or running at right angles to the large corpuscle or obliquely from it. The larger corpuscle is rounded or oval, conical, or sometimes almost dumb-bell shaped. These bodies may appear to touch one another, though usually they are disconnected. Most of these Donovan-Leishman bodies are embedded in the protoplasm of the large endothelial or mononuclear splenic cells, of similar cells in the bone marrow, or of certain lymphatic glands. They may also be seen lying in the protoplasm of the endothelial cells lining the capillary vessels and lymphatics. They are considered by Leishman and Leonard Rogers to be organisms in an intermediate stage of development of either a Trypanosoma or some form of Herpetomonas. Rogers, who succeeded in cultivating them outside the body, described changes which he considers are associated with this latter germ. Paton goes further than this, and states that the Leishmania donovani LaV. et Mesn. taken up by the bed bug closely resembles in Dr. Grüber's type of the Herpetomonas of the common house-fly. It is thought that the Leishman–Donovan bodies are the tissue parasite stage, and that the herpetomonas stage is probably to be sought for in the blood of the patient.

Tsetse-Fly Disease (Trypanosomiasis).—The interesting observations carried out by Sir David Bruce have invested the tsetse-fly with an entirely new significance and importance. In 1895 Bruce first observed that in the tsetse disease—"ngana"—there may be found a flagellated haematozoan closely resembling the Trypanosoma Evansi found in Surra. This, like the Surra organism, is very similar in appearance to, but considerably smaller than, the haematozoan often found in the blood of the healthy rat. It has, however, as a rule a single flagellum only. A small quantity of blood, taken from an affected buffalo, wildebeest, koodoo, bushbuck or hyena—in all of which animals it was found by Bruce—when inoculated into a horse, mule, donkey, cow, dog, cat, rabbit, guinea-pig, rat or mouse, produces a similar disease, the organisms being found sometimes in enormous numbers in the blood of the inoculated animal, especially in the form of the rat and of the guinea pig. They cause in the rat the disease in a healthy animal only when it has first charged itself with blood from a diseased animal, and he produced evidence that Glossina morsitans is not capable of producing the disease except by carrying the parasites from one animal to another in the blood that it takes through its proboscis into its stomach. The parasites taken in along with such blood may remain in the stomach and alive for a period of 118 hours, but shortly after that the stomach is found to be empty, and the parasites contained in the excrement no longer retain their vitality. The mode of multiplication of these organisms has been studied by Rose-Bradford and Plimmer, who maintain that the multiplication takes place principally in the spleen and lymphatic glands. The tsetse-fly parasite, however, is still imperfectly understood, though much attention is now being paid to its life-history and development.
Sleeping Sickness (Trypanosomiasis).—To the group of diseases caused by Trypanosomes must now be added sleeping sickness. This disease is due to the presence and action in the human body of a form known as T. gambiens (Dutton).

In order to demonstrate the parasite in the blood of a case of sleeping sickness, where they are very scanty and difficult to find, the best method is repeated centrifugalization of the blood (Bruce), 10 c.c. being treated at a time; then the sediment in a number of these tubes is collected and again centrifuged. The living trypanosome may, as a rule, be distinguished in this final sediment, even under a low power of the microscope. The organism may be found in greater numbers in the cerebro-spinal fluid of a case in which the symptoms of sleeping sickness have been developed, though centrifugalization of from 10 to 15 c.c. of the cerebro-spinal fluid for half an hour may be necessary before they can be demonstrated. Greig and Gray, at Mott’s suggestion, were able to find the organism in the fluid removed by means of a hypodermic syringe from the swollen eyelids that appear as one of the earliest signs of the disease. Examined fresh and in its native fluid or in normal saline solution it is seen as an actively motile, highly refractile, somewhat spindle-shaped organism (see Plate I., fig. 9). The anterior end is prolonged into a pointed flagellum, the posterior end being slightly blunted or rounded. This organism darts about rapidly between the red blood corpuscles or other corpuscles or particles, and shows rapid undulations, the flagellum beating quickly and the body following the flagellum. In this body a couple of very bright points may be seen. On staining by Leishman’s stain (see under Kala-azar) the general protoplasm of the body is stained blue and is somewhat granular. This trypanosome is from 15 to 25 μ in length (without the flagellum, which is from 5 to 6 μ) and from 1-5 to 2-5 μ wide. In the centre of the spindle-shaped mass is a very distinct reddish purple oval corpuscle corresponding to the larger of the two bright points seen in the unstained specimen; this, the nucleus of the trypanosome, is slightly flattened. Now the posterior or blunt end of the organism is a second, but much smaller, deeply stained reddish purple point, the second of the bright spots seen in the unstained specimen; this is known as the micro-nucleus or centrosome. Around the micro-nucleus is a kind of court or area of less deeply stained protoplasm, arising from or near which and running along the margin of the body is a narrow band with a very sharply defined wavy free margin. This thin band of protoplasm seems to be continuous with the large spindle-shaped body of the trypanosome, but at the free margin it takes on the red tint of the micro-nucleus instead of the blue tint of the protoplasm. The undulatory membrane, as this band is called, is narrowest at the posterior end, getting broader and broader until the micro-nucleus is reached, beyond which it tapers off irregularly until finally it merges in the flagellum. In sleeping sickness the presence of this organism is usually associated with distinct anaemia, the red cells being diminished in number and the haemoglobin in quantity. Along with this there is an increase in the number of mononuclear leucocytes.

The trypanosome is carried to the human patient by the Glossina palpalis, in the proboscis of which the organisms may be seen for some short time after the insect has sucked blood from an infected patient. These trypanosomes have been found living and active in the stomach of this insect up to 118 hours, but after 140 hours no living parasites can be demonstrated. They undergo no metamorphoses in this intermediate host and are simply discharged in the intestinal excreta. It may be readily understood that the trypanosome under these conditions soon loses its virulence, and can no longer be infected by the bite of the Glossina for more than 48 hours after the infected blood has been ingested by the fly. The organism may remain latent in the human body for a considerable period. It certainly sets up very tardily any changes by which its presence can be detected. The first symptoms of its presence and activity are enlargement of the lymphatic glands, especially those behind the neck, a condition often accompanied by irregular and intermittent fever. After a time, in from three months to three years, according to Bruce, the organism gains access to the fluid in the cerebro-spinal canal. Accompanying this latter migration are languor, lassitude, a gradually increasing apathy, and finally profound somnolence.

The incubation period, or that between the time of infection and the appearance of the symptoms associated with trypanosomiasis may be as short as four weeks, or it may extend over several years. The inhabitants of the island of Senegal who have lived in Casamance do not consider themselves safe from the disease until at least seven years after they have left an infected area. At first, amongst negroes, according to Dutton and Todd, there is no external clinical sign of disease except glandular enlargement; in malattos and whites an irregular and intermittent fever may be the chief sign of infection, "the temperature being raised for two to four days, then falling to normal or below normal and rising again for three to five days." In other cases the fever is of the septic type, the temperature being normal in the morning but rising in the evening to 101-3° or 102-2° F., rarely to 103° F., the curve differing from that characteristic of malaria in which the rise usually takes place in the morning. Moreover, in sleeping sickness there are no rigor before the rise of temperature and but slight sweating, such as there is usually occurring at the end of the rise. Here again we have a distinction between the malarial condition and that of sleeping sickness. The respiration and the pulse rate are increased both during the febrile and the non-febrile attacks; the respiration is from 29 to 30 a minute, and the pulse rises to 90, and even up to 140, a minute, according to the degree of cardiac excitability which appears to be constantly present. The localized swelling and redness are seen as puffiness of the face, oedema of the eyelids and ankles and feet, congested erythematous patches on the face, trunk or limbs. Anaemia, general weakness and wasting, at first very slightly marked, gradually become prominent features, and headache is often present. The enlargement of the spleen appears to go on concurrently with enlargement of the lymphatic glands. Manson points out that trypanosomiasis may terminate fatally without the appearance of any characteristic symptoms of sleeping sickness, but as a rule the "sleeping" or second stage supervenes. The temperature now becomes of the hectic type, rising to 102-2° F. in the evening and falling to 98-6° F. in the morning. Here again there are no rigors or sweating. During the last stages of the disease the rectal temperature may fall as low as 95° and for the last day or two to 92° F., the pulse and respiration falling with the temperature. The irritability of the heart is still marked. Headache in the supranorbital region, and pain in the back, and even in the feet, have been described. Activity and intelligence give place to laziness, apathy and dullness; the face loses its brightness, the eyelids approximate, and the muscles around the face, neck and shoulders become flaccid. The patient becomes drowsy, and when questioned replies only after a marked interval. Fibrillary tremors of the tongue and shaking of the hands and arms, distinct even during rest, become increased when any voluntary movement is attempted. These tremors may extend to the lower limbs and trunk. Epileptiform convulsions, general weakness and progressive emaciation come on, and shortly before death there is incontinence of urine and faeces. "The intellectual faculties gradually become impaired, the patient has a certain amount of difficulty in understanding what is said to him, and becomes emotional, often crying for no reason whatever; delirium is usually absent, the drowsiness increases and the patient’s attitude becomes characteristic, the head falls forward on the chest and the eyelids are closed. At first the patient is easily aroused from this drowsy condition, but soon he reaches a stage in which he falls sound asleep almost in any attitude and under any conditions, especially after meals. These periods of sleep, which become gradually longer and more profound, lead eventually to a coma condition from which the patient can be aroused only with the greatest difficulty. It is at this stage that the temperature becomes normal and death occurs." Nabarro points out, however, that this condition of drowsiness and sleep, leading eventually to coma, is by no means invariably present-
PARASITIC DISEASES

In the early part of the sleeping-sickness stage patients often sleep more than usual, but later do not sleep excessively. They become lethargic and indifferent to their surroundings, however, and often lie with their eyes closed. When spoken to they hear and understand what is said to them and after a longer or shorter interval give a very brief reply.

The leucocytosis that occurs during the course of this form of trypanosomiasis is due, apparently, to secondary or terminal bacterial infections so frequently associated with the disease in its later stages. The first stage of the disease, that of fever, may last for several years; the second or nervous stage with tremors, &c., from four to eight months. It is quite exceptional for the disease to be prolonged for more than a year from the time that the nervous symptoms become manifest, though a European who contracted trypanosomiasis in Uganda, having delusions and becoming drowsy within the year, did not die of sleeping sickness until more than eighteen months from the onset of the nervous symptoms.

The Glossina palpalis is not found in swamps. It affects a belt of from ten to thirty yards broad along banks bounding it. The bite of the fly is sometimes transmitted by the bite of a dog, the animal in which the so-called fables of the streets occurs. The puppy is specially dangerous, as, although it may be suffering from rabies when the saliva contains an extremely excited virus, the animal may exhibit no signs of the disease until after the time of its death. The other animals that may be affected " naturally" are dogs, cats, foxes, horses, cows and deer; but all warm-blooded animals may be successfully inoculated with the disease. The principal changes met with are found in the nervous system, and include distension of the perivascular lymphatic sheaths, congestion and oedema of the brain and spinal cord and of the meninges. Haemorrhages occur into the cerebral ventricles of the brain, especially in the floor of the fourth, and on the surface and in the substance of the medulla oblongata, and the spinal cord.

In addition to these small haemorrhages, collections of leucocytes are met with in hyperaemic areas in the medulla oblongata and pons, sometimes in the cortical cerebral tissue and in the spinal cord, in the perivascular lymphatics of the grey matter of the anterior horns and in the white matter of the postero-internal and postero-external columns. Here also the nerve cells are seen to be vacuolated, hyaline and granular, and often pigmented; thrombi may be present in some of the smaller vessels, and the collections of leucocytes may be so prominent, especially in the medulla, that they have been described as military abscesses. Haemorrhages are also common in the various mucous and serous membranes; hyaline changes in and around the walls of blood-vessels; proliferation of the endothelium; swelling and vacuolation of nerve cells; pericellular infiltration with leucocytes, and infiltration of the salivary glands with leucocytes (Coats). An increased number of leucocytes and microcytes in the blood has also been made out. The virus, whatever it may be, has a power of multiplying in the tissues, and of producing a toxic substance which, in the case of tetanus toxin, appears to act specially on the central nervous system.

In recent years fresh interest has been aroused in the morbid histology of the brain and cord in hydrophobia by the appearance of Negri’s description of “bodies” which he claims are found in the central nervous system only in hydrophobia or rabies (see Plate I, fig. 3). These bodies, which are rounded, oval, triangular, or slightly spindle- or sausage-shaped, when stained consist of a red (acidophile) basis in which stand out small blue (basophile) granules, rods and circles, often situated within vacuoles. A small central point which is surrounded by no clear space is supposed to correspond to the nucleus of a protozoan. But this can be little more than a suggestion. The Negri bodies are certainly present in the central nervous system in cases of hydrophobia, and have not been found in similar positions in any other disease. They are present in large numbers, even at an early stage of the disease, although they are so small that they may easily escape detection, so small indeed that they may pass through the pores of a Berkefeld
PARASITIC DISEASES

filter, the filtrate in such cases being capable of acting as a rabid virus. In the more chronic cases and in the later stages of the incubation period, the Negri bodies may become fewer in number, and may be easily seen under the microscope. They are from 0.5 to 2 μ in diameter—the longer the course of the disease the larger the bodies, these larger forms seldom if ever being met with in specially susceptible animals, which soon succumb to the disease. The Negri bodies may be constricted in the middle, or if somewhat elongated, there may be two or three constrictions which give it the appearance of a string of sausages. They may be met with in almost all the nerve cells of the central nervous system in well-developed cases of hydrophobia, but they are most numerous and are found most readily in the cells of the cornu ammonis, and then in the Purkinje cells of the cerebellum.

Although there are several methods of preparing these organisms for microscopic examination, the following is perhaps the simplest. A fragment of the grey substance, say from the cornu ammonis, is taken from a section made at right angles to the surface and placed on a slide about one inch from the end. A coverslip is now “pressed up” until it is spread out in a moderately thin layer; then the coverslip is moved slowly and evenly over the slide, leaving the first three-quarters of an inch of the slide clear. In making the smear only slight pressure is used, the pressure beginning on the edge of the coverslip away from the end of the slide towards which the coverslip is travelling, thus driving more of the nerve tissue along the smear “and producing more well-spread nerve cells.” The smears are then air-dried, placed in methyl-alcohol for one minute, and then in a freshly-prepared mixture of 10 c.c. of distilled water, three drops of a saturated alcoholic solution of permanganate of potash, and six drops of saturated methyl-alcohol solution of grey glass. The smear is then washed in 5% solution of formaldehyde, and is stained with an emulsion of 5% solution of permanganate of potash in alcohol, which is warmed until steam rises; the stain is then poured from the specimen, which after being rinsed in water is allowed to dry and is then mounted in Canada Balsam.

The nature of the disease produced by the inoculation of saliva from a rabid animal appears to depend upon (1) the quantity of the rabic virus introduced; (2) the point of its introduction; (3) the activity of the virus. Thus by diluting the poison with distilled water or saline solution and injecting small quantities, the period of incubation may be prolonged. Slight wounds of the skin of the limb and of the head are followed by a long incubation period; but when the inoculation takes place in the tips of the fingers or in the skin of the face, where nerves are numerous, and especially where the wound is lacerated or deep, the incubation period is much shorter and the attack usually more severe. This, as in tetanus, is accounted for by the fact that the lymphatics of the nerves are much more directly continuous with the central nervous system than are any other set of lymphatics. The poison appears to act directly upon the cells of the central nervous system.

A rise of recent researches on hydrophobia, two methods of treatment—one of which, at any rate, has been attended by conspicuous success—have been put into practice. The first of these, Pasteur's, is based upon the fact that rabic virus may be intensified or attenuated at will. Pasteur found that although the virus taken from the cerebrospinal fluid of the dog always produces death in the same period when inoculated into the same animal, virus taken from other animals has not the same activity. If passed through a succession of monkeys it may become so attenuated that it no longer reproduces the “dog rabic virus,” which is fatal to the dog, or the “dog rabic virus of the monkey,” which kills in twelve to fourteen days, be passed through a series of rabbits, the virulence may be so exalted that it may kill in about six days: its activity cannot be increased beyond this point by any means at present at our disposal. This intensified virus was therefore named virus faste by Pasteur, and it forms a standard from which to work. He found, too, that under certain conditions of temperature the virus may be readily attenuated, one hour at 50° or half an hour at 60° C. destroying it. A 5% solution of carbonic acid acting for half an hour, or 1 g per 1000 solution of bichloride of mercury or acetic acid or permanganate of potash, brings about the same result, as do also exposure to air and sunlight. The poison contained in the spinal cord of the rabid animal may be dried and stored in a sterile glass flask plugged with cotton-wool and containing a quantity of potassium hydrate—a powerful absorbent of water. At the end of twenty-four hours the activity of the virus is found to have fallen but slightly; at the end of forty-eight hours there is a still further falling off, until on the fourteenth or fifteenth day the virus is no longer lethal. With material so prepared Pasteur treated patients who had been bitten by mad dogs. On the first day of treatment small quantities of an emulsion of the cord exposed for thirteen or fourteen days in saline solution are injected subcutaneously, and the treatment is continued for from fifteen to twenty-one days, according to the severity of the bite, a stronger emulsion—i.e., an emulsion made of a cord that has been desiccated for a shorter period—being used for each succeeding injection, until at last the patient is injected with an emulsion which has been exposed to the air for only three days. In the human subject the period of incubation of the disease is comparatively prolonged, owing to the insusceptibility of the tissues to the action of this poison; there is therefore some chance of obtaining a complete protection or cure if treatment be commenced within a few hours after the bite. The virus introduced at the bite has then no more chance of affecting the nerve centres than has the strong virus injected in the late stages of the protective inoculation: the nerve centres, having become gradually acclimatized to the poison of the rabic virus, are able to carry on their proper functions in its presence, until in time, as in the case of microbial poisons, the virus is gradually neutralized and eliminated from the body. Various modifications and improvements of this method have from time to time been devised, but all are based on, and are merely extensions of, Pasteur's original work and method. As soon as it was found that antitoxins were formed in the tissues in the case of an attack of tetanus, attention was drawn to the necessity of determining whether something similar might not be done in the production of an antirabic serum for the treatment of rabies. Babes and Lepp, and then Tizzoni and his colleagues Schwarz and Centanni, starting from virus faste, obtained a series of weaker inoculating materials by submitting it for different periods to the action of gastric juice. Beginning with a weak virus so prepared, and from time to time injecting successively stronger emulsions (seventeen injections in twenty days) into a sheep, they succeeded in obtaining a serum of such antirabic power that if injected in the proportion of 1 to 25,000 of body-weight, an animal is protected against a lethal dose of virus faste. The activity of this serum is still further reinforced if a fresh series of injections is made at intervals varying from two to five months, according to the condition of the animal, each series occupying twelve days. This antirabic substance stored in the blood has not only the power of anticipating (neutralizing?) the action of the poison, but also of acting as a direct curative agent; as a prophylactic agent, readily kept in stock and easily and rapidly exhibited, it possesses very great advantages over the inoculation method. It must be borne in mind that the longer the period after the infection the greater must be the amount of serum used to obtain a successful result.

As regards the necessity for any treatment it may be pointed out that although the saliva of a rabid dog may be infective, three out of five dogs inoculated with the saliva of one of these animals show the development of any symptoms of the disease death takes place almost invariably within six days of the first symptom. If therefore the animal remains alive for ten days after the patient is bitten, there is no necessity for the antirabic treatment to be applied and the patient need fear no evil results from the bite.
